

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

Water Buffalo

Water Buffalo. This animal is found in the East Indies, China, and other parts of Asia. It is a very useful animal, and is often used for carrying loads.

Water Buffalo. This animal is found in the East Indies, China, and other parts of Asia. It is a very useful animal, and is often used for carrying loads.

THE FARMER'S MAGAZINE.

JULY, 1840.

No. 1.—VOL. II.]

[SECOND SERIES.

PLATE I.

The subject of our first Plate is a Devon Heifer, aged two years and three months, bred by and the property of Mr. Paul, of Compton Pauncefoot, Somerset. This Heifer was exhibited at the first meeting of the Royal Agricultural Society of England, held at Oxford, in July, 1839, and obtained a prize of Fifteen Sovereigns, as "the best in-calf Heifer, not exceeding three years old." This animal, as well as three others of the same breed, for each of which Mr. Paul obtained prizes, were much admired as very complete specimens of Devon Cattle.

PLATE II.

The subject of our second Plate is three Southdown Wether Sheep, bred by and the property of Mr. Jonas Webb, of Babraham, Cambridgeshire, exhibited by him at the Show of the Smithfield Club, in December, 1839, and for which a prize of Ten Sovereigns was awarded to him, as also the silver medal as the breeder. Independent of the known character which Mr. Webb has attained as a breeder of Southdowns, there is an additional interest excited in reference to his flock, he being considered a formidable rival to the old established breeders of this sort of sheep on their native downs in Sussex. We anticipate a hard contest for the prizes for this description of sheep to be awarded at the forthcoming meeting of the Royal Agricultural Society of England at Cambridge, on the 15th instant.

ESSAY,

CONTAINING AN ACCOUNT OF THE IMPROVEMENTS WHICH HAVE TAKEN PLACE IN THE AGRICULTURE OF SCOTLAND SINCE THE FORMATION OF THE HIGHLAND SOCIETY.

(Submitted in competition for the Prize offered by the English Agricultural Society, in 1839.)

Before proceeding to the subject of which he ventures to treat, the writer of this essay begs to premise that it will be his endeavour to avoid entering into any detail, or encumbering the Essay with anything which appears to him not indispensable for accomplishing the task he has undertaken. The limits to which an essay of this kind may be expected to be confined seem to forbid the introduction of lengthened details, either historical or practical, and such elaboration would be the less
OLD SERIES.]

excusable, when the writer recollects not only the extensive knowledge possessed by the honourable gentlemen whose names appear among the directors of the English Agricultural Society, but that the information referred to, may be found in many of the numerous works which have appeared on agriculture. The writer, therefore, humbly conceives, that it would be to impose upon his readers, not only a tedious, but an unprofitable task, were he to do more than trace the leading features in history of Scotch agriculture during the period assigned. He will especially notice those which seem to illustrate the progressive improvement of agriculture, both as a science and as an art; and will point out those circumstances which he conceives have enabled the Scotch farmer, within that period, so successfully to combat the difficulties which soil and climate have presented.

In following out the plan of the essay, it is proposed in the first place, to take a concise view of the state of Scotch agriculture about the year
B [No. 1.—VOL. XIII.

1784, when the Highland Society was instituted, and to point out the chief obstacles which were opposed to the improvement of the art, at that time. In the next place to enquire how far these obstacles have been removed, to trace generally the progress of improvement since 1784, and to notice the nature and extent of the influence which the Highland and Agricultural Society has had in promoting that improvement. And, finally, to describe the progress and present condition of a particular district in which improvements have of late years been carried to considerable extent under the writer's immediate observation.

1. Prior to 1784, there was upon all Scotch farms a recognized division of what was termed infield, or croft lands, and outfield lands, and upon those farms having any proportion of muirs or mountainous ranges, infield or croft lands, outfield lands, and pastures.

That which was then considered the arable land of the country, comprehended what was termed infield and outfield land; the former being that portion of the farm which lay contiguous to the residence of the occupier, was partially enclosed and subdivided, and had been subjected to cropping from time immemorial; the latter being the more distant part of the farm was rarely enclosed or subjected to cropping. At this time the infield land seems to have extended to no more than about a tenth of the whole arable land, infield and outfield.

The pastures comprehending the mountainous ranges and muirs appear to have been equal in extent to more than one-half of all the arable land in the country.

In districts of Scotland, celebrated for their cultivation at that time, enterprising agriculturists were to be found who had adopted plain summer till, and the growing of white and green crops, alternately, on their infield lands, but pasturage did not form any regular part in that rotation, and the sowing of grass seeds and turnips, did not extend over more than a twentieth part of the best cultivated land. The more general practice pursued throughout the country upon the infield land was the system of growing white or corn crops, and green crops without regard to regular rotation, and without the adoption of plain summer till. The system, if it can be so called, was different in almost every county. To the outfield, being about nine-tenths of the whole arable lands, the sowing of green crops had not extended, and when any portion of those lands happened to be cultivated, two or three white or corn crops were taken in succession from the same spot, and then it was left to nature to restore it to grass.

The agricultural plants then generally cultivated in Scotland were the following:—

Wheat. Common beardless, white and red, varieties of *Triticum Sativum*.

Barley. Bere or big.

Oats. Old black; a variety known by the name of white oats, comparatively rare, and the bristle pointed oat in the Highlands.

Rye grass. No particular variety.

Red and white Clover. The same.

Turnips. The common white round; red top white, and green top white.

The following were just beginning, and only beginning to be known, and were introduced but very partially.

The woolly eared wheat.

One variety of two, and one of six rowed barley. The Friesland, Poland, white, Tartarian and Scotch grey and dun oats.

The common grey pea.

The horse bean, and,

Potatoes.

At this time the fertilizing of the soil was entirely dependent upon such manure as was made upon the farm. The application of lime was ill understood, and little practised. To a certain extent shell marle, dug from the bottom of peat mosses, was employed for those purposes to which lime is now applied. This material, however, though it possesses some of the properties of lime, is very far inferior in its adaptation to agricultural purposes. It is always combined with a large proportion of clay, which renders it unsuitable for many descriptions of soil, and from the quantity required for its useful application, the expence of carriage forms an objection to it, almost unsurmountable.

The breeding of sheep and cattle, generally speaking, was entirely confined to the pastures. The former were known by two sorts, the short and long, or black, and whitefaced or Cheviot. The one being considered most suitable for exposed situations and the coarsest pasturage; the other for the sheltered and better descriptions of pasturage.

In cattle, the breeds were more varied, but it would be quite unprofitable here to enumerate these. The differences consisted merely in certain points peculiar to the different districts. In none of the sorts did any of those properties predominate which are favourable to early maturity.

The improvement of the breeds by proper selection not being attended to, and that, in combination with the general practice of overstocking the pastures in summer, and providing no food for the severities of winter, naturally occasioned much mortality, stunted growth in the animals, and a smaller quantity, and inferior quality, of wool, from the sheep stocks. The feeding of sheep and cattle was then carried to a very limited extent, more dependence being placed on the demand from English dealers than on the prospect of being able to bring them to maturity in Scotland. Such cattle as were then fed for the butcher were principally got from the Highlands, the supply from the more southern counties being then very moderate.

Under such circumstances the barriers to improvement, as may well be supposed, were both numerous and formidable.

Agriculturists were still, for the most part, found congregated in villages, or the farm buildings were situated at some extreme point of the farm, in consequence of which the farmer found himself obliged to apply his manure to the lands which lay contiguous to his residence, termed croft or infield land. These lands were but partially enclosed and subdivided. Generally speaking little attention was paid to any regular alternation of white and green crops; and although most farmers were perhaps impressed with the propriety of husbanding infield land to the greatest advantage, few had seri-

ously considered the means of improving it. The drainage of land was imperfectly understood, and but little practised. The economical use and proper application of lime and manure were not properly attended to, and but little understood. There were few varieties of the different grains and the ignorance which prevailed as to the proper adaption of them to different soils and altitudes, the want of convenient markets, and the little attention to the improvement of live stock, all contributed to the hindrance of improvement. The nature of the climate aggravated these disadvantages, and finally the want of roads, the miserable state in which those that existed were kept, and the rude construction of farm implements, were circumstances which, while they afforded proof of the backward state of agricultural industry, contributed at the same time to retard improvement. That most of these impediments have been surmounted, will appear from contrasting the present condition of rural economy with that which has been described.

Subsequent to the termination of the American war, when the paralysed industry of the country began to revive, landowners finding that there was a corresponding movement on the part of the agricultural community, and that the spirit of enterprise and emulation which was evinced pointed at certain methods of improvement, were thus stimulated to enquire to what extent their own interest was concerned in the result, and in consequence of witnessing the beneficial effects produced by the adoption of a more judicious appropriation of the lands into farms, and the advantage derived from providing accommodation on the spot most suitable for the pursuits of the cultivator, were induced very generally to remove, when necessary, the farm buildings to more central situations of the farms, and thus enabled the occupiers to conduct their operations on more certain and economical principles, putting it in their power to secure their crop at the least possible risk and expence, and to superintend the management of it in the most efficient manner. Farmers were thus also enabled to distribute their manure in more regular proportions, and diffuse it more widely over the arable lands, with vast saving of horse labour. The original style of those buildings was very imperfect, both in arrangement and the accommodation they afforded. Subsequently however, about the year 1810, that public spirited and indefatigable patron of agriculture, the late Sir John Sinclair, having his mind ever directed to what was to be beneficial in rural economy, exerted himself in order to rouse the attention of proprietors to the disadvantages that still existed, and succeeded in doing so to a considerable extent. Farms were at that time much enlarged, and new buildings rapidly made their appearance in those districts capable of regular aration. More recently improvements in this respect have been carried still farther, under the auspices of the Highland Society, and now in the most modern construction of farm buildings, due regard is paid to combine, in every respect, what is suitable for the general economy of the farm.

PLANTATION.

When the future productiveness of the soil (as already referred to) seriously engaged the attention

of land owners, it is natural to suppose that the ungenial nature of the climate would occur to them as one of the most formidable impediments in the way. Until that should be ameliorated, it would have been in vain to expect any considerable success in promoting the art of agriculture. Plantation, that essential precursor, became more general, and as the land selected for growing timber was for the most part taken from the outfield lands, or mountain ranges, the bare aspect of these districts underwent a gradual but progressive change, and a sensible benefit was effected by the shelter thus afforded to the surrounding lands. Inroads were thus yearly made on the uncultivated portion of the arable lands, and large tracts subjected to regular aration. The change became more perceptible during the period of the French war, when landlords had the means of expending a portion of their income, not only on necessary, but ornamental plantation. Within the last twenty years the planting of waste and unproductive ground, has been carried to considerable extent, the climate has thus been sensibly improved and an impetus given to the extension of good husbandry. Many proprietors who have distinguished themselves in this respect, might be mentioned, as corroborative of the preceding statement, but it may suffice to allude to the larch plantations on the estate of the Duke of Athol in Perthshire where utility and profit seem to go hand in hand. These extend now to upwards of nine thousand Scotch acres. The late duke found that the larch would thrive at an elevation of sixteen hundred feet above the level of the sea, while the Scottish fir was barely able to live at nine hundred. At this elevation Scottish firs forty-two years old, were not taller than six feet, while the larches ten years younger, were from forty to fifty feet. In a lower part of the plantation the scottish firs were twenty feet, the larch from thirty to forty. This description of larch has been found to grow in height on an average of the first fifty years sixteen inches. In girth it gains one inch per annum, till it be twenty-four years old, and during the next twenty-four years, it gains one and a quarter inch. The soil of the duke's plantations is disintegrated gneiss, clay, slate, and mica slate. On a wet subsoil the larch rots in the heart at forty years old. The plants are set two yards apart, and are thinned from the twenty-fourth to the thirty-sixth year to four hundred per acre. The weedings are worth 12*l.* per acre. The value of the timber at the end of seventy years, taking four hundred trees to the acre, (each containing a load of timber at fifty shillings) may be estimated at 1000*l.* Taking into account the value of the weedings, and the charges of planting and fencing, rating the land at one shilling per acre, and computing at four per cent. compound interest, the value of an acre of planting may be taken at 40*l.*

DISADVANTAGES ARISING FROM THE WANT OF INTERNAL COMMUNICATION.

The obstacles which were opposed to the improvement of agriculture from the want of proper roads, even so late as 1783, were experienced to a lamentable degree. Not only was it impossible to effect improvements from want of internal communications, but the defects of those public roads then in existence operated most prejudicially to the Cultivators who sent the greatest proportion of their produce to markets. Not only was additional expence incurred in doing so, but they were circumscribed in the means of replacing the abstraction of the home manure. By reference to the

evidence given by Mr. Mc. Adam, before the Committee of the House of Commons in 1819, it appears that when that gentleman visited Scotland in 1783, although the Turnpike Acts had been in existence for twenty years, many of the roads were unmade. The new roads afterwards constructed, were productive of the best effects, but still so late as 1811 the system of making them was very defective, as appears from a discussion which took place about that time in the House of Commons, when the Scotch roads were universally admitted to be much worse than those in England, and indeed to be in a most deplorable state. Gradually however, since that period, but more particularly after the Macadamizing system was generally adopted, they began to vie with the best in the kingdom, and thereby every facility has been afforded to the introduction of the most economical method of transporting farm produce, and the procuring of extraneous manures. The roads termed Parish Roads are now much improved, and agriculture has been sensibly benefited in consequence.

ENCLOSURES.

As farm buildings came to be placed in the most advantageous situations and plantations extended, greater attention was paid to the enclosing and subdividing of the land, according to the nature of the soil and the size of the respective farms. Improvements in this respect became most observable over the arable lands during the course of the war. Subsequently greater attention has been paid to the construction of fences when made of stone, and when of thorns to the proper methods of planting and afterwards nursing them. More recently the advantages of enclosures were extended to the pastoral districts, by all which means the Scotch farmer has been enabled to adopt a more perfect system of cropping and pasturing his land.

CROPPING.

Subsequent to 1784 and prior to 1800, no perceptible change, generally speaking, took place in the system of cropping, described in a former part of this essay, with the exception that the growing of green crops, was extended to the enclosed portion of the outfield lands. At this last mentioned period the high price realized for all descriptions of farm produce stimulated to the adoption of growing white and green crops, alternately, farmers then finding that by this means only, the soil could be rendered most productive. Clear summer till, appears then to have been more generally introduced as part of the rotation, and was considered a material improvement, the land being formerly imperfectly laboured, and cleaned. Subsequent to the termination of the war, when the price of farm produce receded, a proportion of pasturage then formed a part, the advantages of which were soon made apparent; the cultivator being thus enabled not only to reduce his general expenditure, but recover the land that had been previously exhausted by a long continuation of uninterrupted cropping. Afterwards, when agriculturists could command the facilities supplied by the introduction of bones, and rape-cake, as manure, turnips were considered entitled to have a greater share in that rotation, being found advantageous, not only as food for the additional live stock upon the farm, but as the means of producing a greater quantity and a superior quality of manure. From these circumstances a vast contrast can now be made. Instead of the attention of the farmer being, as formerly, confined exclusively to the infield land, a regular alternation, strictly enforced

and attended to, now extends over the whole farm. The manure also is now properly distributed, according to the nature of the soil and cropping. The leading features of the present rotation, consists in the growing of white or corn crops, and green crops, alternately, varying the description of crop according to the nature of the soil and local situation. The greatest possible attention is paid to the turning over of the land in proper season,—to the thorough cleaning of the fallow, whether in clear summer till, or in green crops; proper care is also taken to observe the most advantageous time for depositing the seed, and the most proper state of the land for its reception, and particular attention is given to the selection and changing of seed corn, and all the other roots, grasses, &c. now cultivated.

FARM IMPLEMENTS.

The rude construction of farm implements at the commencement of the period to which the observations in this essay principally apply was a great bar to arable culture. Shortly afterwards the plough, (which of all the implements of agriculture is the most indispensable, being the first breaker up of the soil, and the precursor to every after process,) having been reduced to scientific principles by the late Mr. Small, a mechanic in Berwickshire, found its way into the best cultivated districts and supplanted the old unwieldy implement that preceded it, with its expensive accompaniment of oxen in addition to horses. The attempts made by the ingenious mechanic the late Mr. Meikle to substitute the thrashing machine for the flail, excited considerable interest. Until, however, the impetus which was given to agricultural exertion during the eventful period of the war, farmers generally were not in possession of those essential requisites to the perfection of rural labour. The change which then took place, was as rapid as it was important. Farmers with avidity possessed themselves of all the implements which could be procured, and this demand was met by a corresponding exertion of ingenuity on the part of mechanics, and thus the farming community were yearly benefited both by the introduction of new implements, and by improvements in the construction of those then common. The improved state of the roads has enabled farmers to avail themselves of a lighter and simpler construction of carts, drawn by one horse, which has effected great saving in rural economy, more particularly in situations removed from markets, or where extraneous manures require to be brought from a distance. The thrashing machine, one of the most important of agricultural implements, became very general, and conducted vastly to the benefit not only of the agricultural community but of the country generally. It would be difficult to estimate the advantage conferred by this powerful agent, but it may be mentioned that some interesting and apparently sound calculations on the subject will be found in a work published by an intelligent writer on agriculture, the late Mr. Browne of Markle, in 1811, at which times the machines were by no means so numerous as they are at present, nor so highly improved. In his treatise on rural affairs Mr. Browne has presented the following estimate of the profit that might be derived by the public were thrashing mills used in every case in this country for separating corn from the straw. He calculates:—
1. The number of acres producing grain in Great Britain, 8,000,000. 2. The average produce in quarters at three quarters per acre at 24,000,000. 3. The increased quantity of grain produced

by thrashing mills instead of using the flail at one-twentieth part of the produce or in quarters at 1,200,000. 4 The value of that increased quantity at forty shillings per quarter, at 2,400,000l. 5 The saving in expence of labour at one shilling per quarter, at 1,200,000l. 6 The total profit per annum to be obtained, at 3,600,000l. 7 The actual profit per annum on the supposition, that only half of the grain produced were thrashed by machines, 1,800,000l.

Sir John Sinclair's remark upon this is deserving of attention. "It is not then to be wondered at, that he should pronounce the thrashing mill to be the most valuable implement in the farmer's possession, contending that it adds more to the produce of the country, than any invention has hitherto done, and that it ought to be accounted the greatest improvement that has been introduced into Great Britain during the present age. Since that time also, steam has been attached, which has still further increased, in an economical point of view, the advantage of this implement.

DRAINING.

Draining of land in Scotland, on anything like proper principles, was not much understood nor carried beyond the most restricted limits, until the publication of Mr. Jas. Johnson, land-surveyor, in which he detailed the practice of Mr. Elkington, when the object was the removal of land-springs. This work made its appearance about the year 1800, when, fortunately the farming community was in the most favourable circumstances to profit by the hints it contained. It thus proved highly beneficial. As much of the land in Scotland however, is retentive and not applicable to Elkington's system, improvements in this respect were only effected within certain bounds. At a later period, viz., about the year 1813, the Duke of Portland introduced the practice of tile draining upon an extensive scale. He erected three tile manufactories upon his estate in Ayrshire, and thus proved the advantage derivable from furrow-draining by means of such materials. The example of this nobleman, so worthy of imitation, did not at first meet with that attention it deserved, and fully sixteen or eighteen years elapsed before the agricultural community generally, admitted that furrow-draining, by means of tiles and other materials, was the only effectual method of relieving land from excess of surface water. Since the last mentioned period, manufactories of tiles are numerous all over the country, and thus, by means of Elkington's system, in combination with furrow-draining, much has been done to alter the appearance of and encrease the produce of the arable lands throughout Scotland. The former sickly appearance of the crops, the late period of ripening, and the uncertainty and risk attending the operations not only in harvest, but in spring, autumn, and winter, in a climate so variable, have been moderated, or in some degree removed. The land is not liable to poaching. It can be more thoroughly laboured and cleaned; and, generally speaking, ploughed at any season, and in most circumstances with advantage. Labour is economized, the benefits of stimulating and enriching manures secured to the fullest extent, and a more ample produce and superior quality of grain obtained.

With regard to the drainage of land laid out in pasture, the effects have been no less obvious. Rushes, and other aquatic plants have disappeared. The finer grasses have risen more abundantly, and

are not injured by the treading of the cattle. The capabilities of maintaining stock have been thus increased to an incredible extent, independent of the superior size and quality of the stock produced. When cut in hay, the quality of those new grasses is superior and of greater value, and in addition to what has been already stated, green crops can now be grown with advantage on every part of a well-drained farm, and these profitably substituted for a clear summer till, by which last process alone the land could have been previously dressed in a husbandmanlike manner.

The drainage of hill pasture land has been practised to great extent within the last twenty years. This improvement is effected by cutting surface drains about fourteen inches deep, (and generally of the same dimensions in breadth) and directing them obliquely along the declivity. This has enabled stock farmers in these districts not only to adapt a more suitable and profitable description of sheep in many cases to the pastures, but to improve the quality of the old stock, where change was advisable. The unwholesome quality of the plants produced on such pastures, with the other disadvantages attending the sheep treading constantly on land surcharged with water, proved fatal to vast numbers, from various diseases, but more particularly that destructive malady, the rot. Independent therefore of the improvement that has taken place in the description of grasses natural to such altitudes, and the benefits resulting to the occupiers in consequence, the climate of the country has been sensibly improved, and greatly to the benefit of agriculture. The effects of general drainage is peculiarly observable in the rapid increase of the rivers throughout Scotland after rain, and the as sudden subsidence when the weather becomes dry. It is also worthy of remark that agues, so prevalent in Scotland at one time, are now seldom or never heard of.

LIME AND MANURES.

As the country became intersected by proper communications the use of shell marl, as a manure, was gradually superseded by the employment of lime,—which, although brought, it might be, from a great distance, was found to be more beneficial and economical. Some idea of the extent to which it is now employed on land in Scotland may be formed by reference to the Highland Society's published Transactions, (vol. 11. p. 57). From an enquiry instituted by that society in 1834, the lime used as manure in the previous year, 1833, is estimated in round numbers at 5,060,000, bushels. The general application of lime, in combination with drainage, has been the means of reclaiming, and bringing into a high state of cultivation, a very great extent of the outfield lands. More recently ground bones have been extensively used in the growing of turnips, and the use of rape cake, as a manure, has been found very efficacious, and has rapidly increased. So late as 1815, it was with difficulty the Scotch farmer could be induced to make trial of these manures, even experimentally. Both, but particularly bone dust, are now in great request, and some idea may be formed of the extent to which they are employed from the following statements, extracted from a return made to Parliament by the Inspector General of Imports and Exports in 1833.

REPORT OF COMMITTEE OF HOUSE OF COMMONS.

Declared value of bones of animals and fish

(except whale bones) imported into Scotland to be used as manure....In 1821 £ 69 17 0
dododo1829 12,322 4 9
dododo1832 13,908 1 1

} Declared Value.

	cwt.	qrs.	lb.
Rapeseed, linseed, and other oilcakes in.... 1821	none		
do....do....do.... 1822	100	0	0
do....do....do.... 1829	34,587	1	27
do....do....do.... 1832	444,491	3	21

What proportion rapeseed bears to the other materials with which it is combined in this return does not appear, but there can be no doubt the quantity was very great.

Mc'Culloch's STATISTICAL ACCOUNT, 1837, vol. 1. pp. 529.

According to the best authorities the arable lands in Scotland are estimated at about 2,400,000 acres, which are distributed as follows:—

In Wheat.....	220,000
Barley.....	280,000
Oats.....	1,275,000
Beans and Peas.....	100,000
Potatoes.....	130,000
Turnips.....	350,000
Flax.....	16,000
Gardens.....	32,000

2,403,000

When it is considered therefore, that rapeseed is applied, more or less to each of these divisions, or descriptions of crop, in Scotland, it appears evident that the quantity made use of composes by far the larger part of the aggregate amount in the return. It could have been wished that access might have been obtained to a similar official statement showing how far the importation had increased since 1832. But although there is no opportunity of making such reference, the following account, which has been kindly furnished from a source which may be relied upon, will, to a certain extent, supply the defect. It exhibits a statement of the amount of duty upon bones and rapeseed, linseed, and other oilcakes, imported into the United Kingdom for home consumption, during the two years antecedent to the reduction of duty in 1816, and again in the year 1837.

Bones of Cattle, and of other animals, and of fish (except whale-bones).				Rapeseed, linseed, and other oil-cakes, entered at the Custom House, under one general head.			
Declared Value.	Rate of Duty.	Amount of Duty.		Quantity	Rate of Duty.	Amount of Duty.	
In	£	£ s. d.	£	Cwts.	per cwt.	£	
1814	557	31 13 4	176	43,011	1 7	3,395	
1815	585	31 13 4	265	16,897	1 7	1,300	
1837	245,823	1 0 0	2331	795,851	0 2	6,756	

In the foregoing table there is no distinction of the quantities imported into Scotland, but it seems not too much to assume that the ratio of increase in that country has been equal to that which has taken place in other parts of the kingdom. Upon this data it will be found that the declared value of bones imported into Scotland was 37,205*l.*, while the amount in 1832 was only 13,908*l.*, being little more than a third of that amount. Similarly the quantity of rapeseed, linseed, &c., &c., imported into Scotland, in 1837, will be found to be 82,788 cwts., the quantity in 1832 being only 46,238, not much more than the half. There is no doubt the

demand from agriculturists in Scotland has continued to increase. Having alluded to bones and rape cake, in exemplification of the extent to which manure is now employed, the writer may further observe that at no distant date the town of Edinburgh paid many hundreds per annum to induce people to remove the dung from the streets. In 1813, after the adoption of a different method, the sum it sold for amounted to 915*l.*, and what has already been disposed of in this present year, 1838, amounts to 8,890*l.* The quality of this description of manure has been yearly falling off from local causes.

That the better cultivation of Scotland may be attributed to such causes, no one can dispute, and that by the spirited manner in which farmers availed themselves of them, the rent of land has been maintained, is equally undeniable. The growing of turnips and barley has been thus attempted where formerly the hilly nature of the land presented a complete barrier to the application of manure. Independent of the advantages gained from the increased breadth now sown with these crops, in situations removed from large towns and cut off from local advantages, the superior culture of the artificial grasses has been secured. Thus additional facilities for reproducing manure has been sensibly increased.

Farmers in the neighbourhood of distilleries have, in addition, derived great advantage from the use of the offals in feeding their live stock, and improving the quality of the farm-yard composts. Other extraneous manures, such as soot, liquid manure, &c., have been found most beneficial in Scotch practice for certain purposes. In farm-yard dung there has been a decided improvement in its preparation and application. The modern style of farm buildings has enabled the farmer to keep more live stock in the yards, and the general practice of feeding these, in part with linseed cake, has not only increased his means of doing so, but at the same time enriches the manure, whilst greater attention is now bestowed upon the collection and applying of it afterwards.

VARIETIES OF GRAIN.

The introduction of many new species and varieties of grain, and the superior knowledge which has been acquired as to their adaptation for certain soils and situations, in a great measure relieve the farmer of that risk, to which he was formerly exposed, by sowing the kinds not suitable for the land. There is no situation, suitable for cultivation, where a variety may not now be sown, which in an average of years will mature and make a moderate return. However much may remain to be accomplished, it is gratifying to reflect upon the progress which has been made in ascertaining the proper descriptions to be sown, in order to insure the greatest amount of produce. The agriculturist has now the selection of upwards of

55	varieties	of wheat.
17	"	of barley.
38	"	of oats.
163	"	of potatoes.
13	"	of beans.
20	"	of peas.
39	"	of turnips.
17	"	of clovers,

and a much extended and yearly cultivation of natural permanent grasses.

The substitution of stock, instead of sample markets, within a recent period, has been of great utility to the grain growing farmer, and the more

judicious arrangements now made for the sale of live stock at regular intervals, and in central situations, has tended much to facilitate the operations of the stock farmer. In Edinburgh, down to so late a period as the year 1827 there was no stock market. There, and throughout Scotland, grain was sold by sample, a mode of dealing attended with many disadvantages, and peculiarly liable to engender disputes. At the time mentioned, a stock market was opened in the metropolis, and the benefits of it very generally felt. The practice was followed successively in other places, and has now been generally adopted over the country. Few had debts now occur; in general, the farmer can always have an opportunity of either increasing, or decreasing his stock any week in the year, and every transaction can be entered into with the greatest safety, as credit is never expected to be given or received.

LIVE STOCK.

In this branch of rural economy, very great improvements have taken place since the period already alluded to, when pasturage assumed a prominent part in the rotation of cropping practised in Scotland. The introduction of short-horned cattle, and Leicester sheep, led to a comparison between them and the live stock of the country. Observation, experiment, and enterprise, were thus excited, and a much more correct judgment has been imparted to the Scotch stock farmer, of the properties, and habits, both of native and foreign breeds. He has also been led to give more rigid attention to rearing and feeding, and to the propriety of availing himself of the increased facilities for securing early maturity of such stock. These improvements began to appear at the same time with the improvement of pasture lands, which, as has been mentioned, took place since the termination of the last war. Each of those improvements have had a reciprocal effect upon the other, and to those who were acquainted with some of the Muirlands in Scotland at a prior period, the combined effect which they have produced in altering the face of the country, and exhibiting verdant fields where formerly there existed nothing but perhaps a barren moor, has been indeed surprising, and would scarcely admit of being described without risk of appearing to exaggerate.

Other circumstances have been instrumental in promoting the course of improvement. Thus the improved education of the farmers generally, and the desire which has been engendered of obtaining the best information on their pursuits, may be mentioned as having had a powerful effect. This was facilitated by the numerous publications which have issued from the press on agricultural subjects. The surveys of the different counties enabled a comparison to be made of the practices of others; the systems of management detailed in such surveys, being chiefly confined to what had been adopted by the best cultivators; more particularly, however, it may be observed, that much benefit resulted from Sir John Sinclair's statistical account of Scotland, having attracted very generally the attention of Scotch farmers. Indeed the information contained in that work was in a great measure obtained from their own class, and thus an additional stimulus was given to farther enquiry and observation.

PEASANTRY.

It would be unpardonable not to notice with marked admiration, the very great improvement, both physically and intellectually, of the peasantry. That such improvement has gone hand in hand

with the progress of civilization, and the application of science and art to the practice of agriculture must afford an agreeable subject of contemplation to the philanthropist. The peasantry of Scotland are an educated, shrewd, and enlightened class. They have no prejudices against the introduction of machines, for saving labour, and there are few who do not possess very general knowledge of country affairs. The chief amelioration which has taken place of late years in the condition of this class consists in the more general observance of sober habits—the increased taste for personal and domestic neatness and comfort, and the progress they have made (not inferior to that of any other class) in the acquisition of useful information, and the practice of those arts which fall within their sphere.

The establishment of a chair of agriculture in the Edinburgh University has not been without its beneficial effects. That chair was first filled by Dr. Andrew Coventry, whose appointment took place in 1790. This gentleman continued to fulfil the duties with great honor to himself, and advantage to his pupils, until his death in 1831. Upon this event a successor was fortunately found in the present incumbent, Professor Low, whose scientific acquirements and practical knowledge justly entitle his instructions to that respect which they have universally obtained.

The limited capital amongst the farmers 54 years ago, precluded them from carrying any material improvements into effect, but this difficulty was subsequently obviated by the liberal accommodation granted by the Scotch banks, which enabled the farmers to bring their land into a better state of cultivation, and thereby to increase their produce, and derive the greater benefit from the high prices in the course of the French war.

The advantages already alluded to could have operated only to a limited extent, had it not been for the general and indeed almost universal practice in Scotland, of landlords granting leases for a term of years, and the absence of tithes fortunately afforded free scope to that impulse. Finally it may be observed that the recent improvements in steam navigation have been of considerable benefit to the Scotch farmer, in affording the facility of conveying his produce to the best markets.

It is now time to enquire how far the Highland and Agricultural Society of Scotland, has been instrumental in promoting general improvements. There can be no doubt that the meetings and deliberations of the society have had a powerful influence in directing a more general attention on the part of landlords to rural affairs, and thus leading them to acquire a more minute knowledge of farming operations, and of the best means of improving their estates. The premiums offered by the society for essays on agricultural subjects, have induced practical farmers to communicate the result of their experience; and as much judgment was displayed in the selection and manner of publishing those essays, much valuable information was thus diffused, and farmers were stimulated to further enquiry.

The attention of the Highland Society was in the first instance directed exclusively to the improvement of the northern counties, and the amelioration of the state of the inhabitants there. The benefits conferred on those districts by the exertions of the society, exceeded all expectation, but these initiatory steps in the progress of the society, are fully detailed in the society's published transactions, and it seems superfluous here to

refer to them more particularly. The following observations, therefore, will be confined to the consideration of the influence the society has had in promoting general improvement, by subsequently extending its patronage to the whole of Scotland.

The society offered liberal premiums to the occupiers in the different districts of Scotland, for reports of actual improvements of waste or unproductive land, and, in consequence, numerous reports were made by practical farmers. By this means much valuable information was elicited with respect to the method adopted, and the success or want of success of those employed. In general the improvements were effected by draining and liming; the reclaimed land being either continued in permanent pasture, or brought into a regular course of aration, as was considered most applicable to the nature of the soil, or situation of the land. The society having discovered that the method of under-draining was imperfectly understood in Scotland, deputed a person to go to England and study the art under the celebrated Mr. Elkington. On his return, the society patronized the publication of his observations on Mr. Elkington's system, and took every method to ensure an extensive circulation of the work. This report attracted great interest in the farming community, and the draining of land was afterwards pushed to greater extent, and on better principles than heretofore. The society then offered premiums to the farmers who executed the greatest amount of effectual draining upon their respective occupations. Subsequently the attention of the society was directed to furrow draining, and, under its auspices that system has been extensively adopted, with the most beneficial effect. Much valuable information has since been supplied, regarding the different systems practised, and the best methods of manufacturing tiles. The cost of that article has in consequence been much reduced, and the means of carrying on this species of draining have thus been brought within the reach of farmers, in situations of the country, where other materials could not be procured, for rendering that method of improvement practicable. It would be unnecessary to do more than allude to the cultivation of turnips in the southern parts of Scotland, so long celebrated for the superior culture of that valuable root, but in the extension of that system to other districts, the society has borne a prominent part, by offering premiums to the occupiers of land where turnips were not grown, to the extent to be available in the feeding of live stock, the land in those districts being suitable to the cultivation of this important root. Many reports were afterwards transmitted to the society from different competitors describing their mode of culture, and the extent to which they had carried it.

In the improvement of farm-stock the exertions of the society have been most successful. The liberal premiums they awarded to those enterprising individuals who distinguished themselves in the introduction of the improved breeds of cattle and sheep, gave a powerful stimulus to exertion. The imperfections of the native breeds were thus made more evident to stock farmers, and the national prejudices subdued by the advantages which were made apparent, by a judicious selection of females as well as males. Much benefit has been derived from the society obtaining and publishing essays, written by practical men, upon the best methods of rearing and fattening stock, and providing a winter supply of

food for sheep, and thereby increasing their produce, and improving the staple of the wool.

Amongst the many improvements which have been effected in Scotland by the Highland Society, not the least important has been the establishing of a veterinary school, by means of which a knowledge of the treatment of the diseases of domestic animals has been very much improved. This school was established in 1823, under the patronage of the society. For five years previous to that time, however, Mr. Dick, the present professor, had regularly delivered a course of lectures which had been gradually attracting public attention. The patronage of the society gave a new impulse to the energy of the school, and a great increase of the number of pupils took place, which has gradually continued, until the number last session had increased to seventy-one. It may be interesting to know somewhat of the details connected with this subject, the manner in which it is conducted, and the expenses connected with it. The expense of the institution to the society is only 26l. 5s. per annum, as an allowance towards certain extra expenses; all the other burdens connected with it being supported by the professor out of the fees of the pupils. The fees consist of either three guineas for attendance on the lectures each session, or ten guineas as a fee for liberty of perpetual attendance on the lectures, and also for liberty to attend the practice of the professor. The acknowledged zeal and ability of the professor, and the moderation of the fees exacted from the pupils will in some degree account for the gradual prosperity of the school.

The lectures consist of demonstrations of the healthy structure of the domestic animals, making the horse the standard, and comparing the structure of the other animals with him. Having examined the healthy structure, the alterations induced by disease are then shewn and compared with the normal parts, and the means of prevention and cure are then explained. The course extends to about 90 lectures. The practical pupils are examined weekly, and in order to afford sufficient opportunities to the pupil to become practically acquainted with his profession, the professor has established a veterinary dispensary, where he gives advice and medicines gratis, for the animals belonging to the poorer class of carters, hackney men, and cow feeders who apply. The pupils are permitted, after having obtained a sufficient degree of acquaintance with the subject, to perform the requisite operations prescribed for cases, under the directions and superintendence of the professor. The practical pupils enjoy great advantages from the liberality of several of the professors of the university, and the private lecturers allowing them to attend their lectures gratuitously, and the readiness with which animals are procured for dissection in Edinburgh in consequence of the small value of the carcass ensures the pupil being well versed in anatomy. At the conclusion of the second session's attendance the pupil is publicly examined by a committee of medical gentlemen, appointed by the Highland Society, and those who are found qualified receive a diploma. The benefits derived from this institution are such as might have been anticipated. Farmers, as well as country blacksmiths, have acquired a knowledge of the structure and constitution of the horse and other animals, which 20 years ago was scarcely to be found, even among the profession in large towns.

SEEDS, PLANTS, ROOTS, &c.

In accelerating the acquirement of a knowledge of the adaption of the different sorts of seeds, and

plants, to peculiar soils and altitudes, much has also been done by the enlightened exertions of the society. The attention which has been directed to this subject, has led to the improvement of many sorts by careful selection, and culture, to the production of new varieties of superior qualities; and to the introduction into general culture of new genera and species before unknown, or known only botanically.

In the appointment of Mr. Charles Lawson, of the firm of Peter Lawson and Son, as their seedsmen, the society have possessed themselves of a valuable auxiliary, whose extensive knowledge and indefatigable zeal it would be impossible to overrate. He periodically perambulates, not only his own country but the continent, in search of fresh information, which he hesitates not immediately to put the community in possession of, by his publications. At great personal expense he formed, under the patronage of the society, a museum consisting of specimens of seeds, roots, plants, &c., and also models and specimens of all the improved implements used in the cultivation of the soil, the latter of which were supplied from the collection of the Highland society. To this museum the public are invited free of expense. Agriculturists are encouraged to send specimens of the grains, roots, &c., with a description of the circumstances under which they have been produced; and thus by a comparison of all the various sorts collected, the means are afforded of obtaining information as to the most profitable for their adoption.

The annual meetings and exhibitions of this society, shifting, as they have done, from one district of the country to another, have been of great national importance, in congregating on these occasions vast assemblages of all classes of the agricultural community, in the diffusion amongst them of useful practical knowledge, and creating in them a spirit of emulation in their respective spheres of life. Landlords have been brought in contact with the tenantry, in the competitions of their produce. Practical farmers have more duly estimated the real qualities of their own stock, from seeing them placed in competition with others, and have thereby been enabled to form a more correct judgment of the most valuable properties of the domestic animals. The attention of the farmers has at those meetings been beneficially directed to specimens of the most improved seeds, roots, implements of husbandry, drain tiles, wool, cheese, butter, &c., &c., and other useful husbandry articles, then exhibited. The society's patronage has also been given to district exhibitions of farm-stock, and the premiums then given have been attended with great local benefit. Shepherds and other farm servants take great interest in attending those meetings and exhibitions, and it cannot be doubted that their ideas have, by these means, been enlarged and a more perfect knowledge imparted to them in their respective spheres.

The writer will now proceed to the last division of his subject, viz., to allude to a particular district where improvement "can be proved to have taken place." And he selects Peeblesshire, as being one of the most elevated inland counties, and being thus cut off from the advantages of sea-ports, canals, or railroads. It is a district, so to speak, confined to its own resources. It may also be considered as a recommendation for the purpose in view, that Mr. James Allan, one of the tenantry of the district, was the first to carry off the Highland Society's medal for the improvement of waste land. This prize was awarded previous to 1801, and was justly earned by the improvement of 50 acres of barren heath land, situated on the side of a very steep hill, which, in

spite of all the difficulties of soil and situation, was changed in the space of three years from a sterile and unproductive moor, to a field producing excellent crops.

This county lies between 55° 24', and 55° 30' north latitude, and 2° 45' to 3° 33' longitude, west from London. Its extreme length from north to south is about 30 miles, and its greatest breadth from east to west is about 22. According to recent surveys the land cultivated, or occasionally so, is estimated at about 35,000 imperial acres, what has never been cultivated at 206,000; capable of being cultivated 8000, and under-wood nearly 7000.

In taking a superficial view of this county, the impression may be conveyed that it is altogether a pastoral district, as any idea of the extent of the cultivated ground can only be obtained by very minute inspection. The lowest part being 400 feet above the level of the sea, and its highest point 2916 feet.

AMELIORATION OF CLIMATE.

Being one of the elevated districts in Scotland, the climate is naturally moist and unpropitious. Tradition says at one time there was a considerable extent of natural wood; but little remains to bear evidence that such was the case. Even so late as 1800, the artificial wood did not exceed 2000 acres; now there are computed to be upwards of 7000, and the improvement in this respect has been carried on with a view both to ornament and utility. This, in combination with the extensive drainage of the arable land, and likewise sheep pasturage, has ameliorated the climate, and proved highly beneficial both as regards the prevention of disease, and the more early maturity of the cultivated grains, grasses and roots.

THE GREATER EXTENSION OF THE CULTIVATED LANDS, &c., &c.

Formerly cultivation, in its then imperfect state, only extended to what was termed the old croft lands. These lay principally contiguous to water courses, or immediately adjoining residences, and now bear a very insignificant proportion to the arable lands of the county. Accessions were gradually made from uncultivated land, worthy of being cultivated and likewise from what was in a perfect state of unproductiveness, being reclaimed by means of draining, levelling, and afterwards liming. In some cases these were formerly peat mosses, principally under water, or what was covered on barren heath, on gentle declivities.

As cultivation was extended, enclosures were made, and the system of growing white and green crops in regular rotation, with a proportion of pasturage adopted, independent of the manure made upon the farms, extraneous manures are now extensively employed, and the growing of turnip, which, previous to 1800 was hardly practised, is now widely followed over the county, with due regard to their proper management. Within the last 20 years the period of commencing harvest was considered to be a week or two behind the lowland districts of the county. Now it is almost on a par, and the quality of grain produced, more especially barley, may be said to be equal.

The soils are very variable, consisting of moss, clay, sand, and soils having mixtures of these in different proportions. Generally speaking the arable lands are well adapted for the green crop system of husbandry, and as great attention has been paid to enclosures, every facility is afforded for the improvement of the land by pasturage.

It must be admitted, that from the high price of

farm produce during the war, some of the land in this county, as well as many other districts in Scotland, was injudiciously subjected to cultivation. The effects of this are clearly perceptible, and now more rational methods are taken to improve its productiveness. The improved description of farm implements are now common in this district; and it is worthy of remark, that previous to 1800 only 16 thrashing machines were in operation, now there are upwards of 200, and the greater proportion propelled by four and six horse power.

In the recollection of many of the present occupiers, the black faced breed of sheep almost exclusively occupied this county, the cheviot being comparatively rare and confined to one parish (Posso). Now the cheviot breed is computed to bear the proportion of one-half, and, where this change has been judiciously made, much benefit is gained. The calculation may be taken at 100*l.* per annum for every 1000 black faced sheep that have been displaced by cheviots, and this appears still more interesting when, by the last calculation, the number of sheep in the county is estimated at upwards of 102,000.

In the general management of sheep-farms, an improvement has decidedly taken place. Much loss was at one time experienced by over-stocking the pastures, and laying an extra quantity of tar upon the animals, under the impression that it would enable them to bear up better against the severities of winter. Where smearing with tar is still practised, more judgment is displayed, and in many cases stock farmers have adopted other ingredients which are equally efficacious in protecting the animal and does not deteriorate the quality of the wool. More attention is now paid to a proper provision of winter food, to the selection of the rams, and the appropriation of the regular sheep stock to the pastures.

Due attention is now paid to draining those parts of the pastures which are surcharged with water, and thus a more valuable produce from stock is obtained and new sources of wealth opened up.

Prior to improvements taking place on the farm houses and cottages, the Rev. Mr. Findlater, who wrote an able survey of this country, describes the usual construction of the better farm dwellings to have consisted "of a long house of only six feet wall in height; the apartments all upon the ground, the dimensions about 45 by 15 or 16 feet in breadth within walls, no division by partitions within, but the cross partitions effected by close beds, (the close bed is a frame of wood 6 feet high, 6 feet long, and 4 broad) set end to end with a passage between them." The same writer describes that "in one apartment the farmer and his servants sat in the evening, the fire place being in the centre over which there was suspended a frame of lath and plaster, or spars and mats, and reaching within about five feet of the floor. This resembled an inverted funnel which conveyed away the smoke; the inmates sitting round the fire within the circumference of this inverted funnel. The cottages were built with walls of turf, stone buttresses, or wooden posts built into the wall supporting the heavy timbers of the roof."

The general character of farm buildings now, consist of substantial and respectable residences for the occupier, with suitable accommodation in appropriate and comfortable houses to his servants and labourers, and every other necessary convenience required for the farm-stock.

Previous to the construction of the numerous roads which now intersect the county, farm produce

was conveyed to market upon horses, an equal weight being suspended on each side of the animal, and lime was brought home in a similar manner. This method of transport was occasioned and the use of it prolonged by the description of roads to be travelled. Now the county is very well intersected by proper roads and these well kept. The mail-coach travels upon one of them, and the tollamount to near 3000*l.* per annum, independent of what is paid by the post office. Bridges also are now thrown over the river Tweed, which winds itself through the county.

As to what may be the change that has taken place upon the gross rental of the county within the period to which these remarks principally apply, the writer will not hazard an opinion, not being in possession of correct information in that respect. But he may refer to the following statement as corroborative so far of what has been advanced.

Rental of the parish of Peebles in the county of Peebles as taken from the statistical account of that parish, published August 1834.....	7000
Do. as taken from statistical account of said parish published in the year 1794.....	3000
	Increase £4000

Before concluding, the writer may remark that in this attempt to treat, within the compass of an essay, a subject so extensive in its nature as agriculture, and comprehending as it does with its range the well-being of the universe, he may expect to be blamed for the omission of much which may appear indispensable to convey an adequate idea of the unprecedented advance which has taken place within the last 54 years. But his object has been to avoid any reference to the many conflicting opinions of theorists, and to confine himself solely to observation and to practical information derived from those whose skill and experience entitle them to implicit confidence. He has likewise laboured to confine his observations to those connecting links which have mainly contributed to the general result, and to which others are attached in finer gradation. Aware, however, how much remains to be accomplished he respectfully throws himself upon the indulgence of his readers.

A PRACTICAL FARMER.

COMMON SALT FOR CATTLE.

SIR,—“The Farmer's Magazine” being such an excellent medium of communication, I have to thank you that you will allow the following enquiry to pass through it.

Of all medicines Common Salt is perhaps that which is most universally used for cattle; it is cheap, always at hand, and in many diseases excelled by no other medicine. In small doses it is an excellent tonic, in larger quantities, of a pint or so, a powerful purgative; but when given frequently to milch-cows it dries up their milk. Now I have no doubt something may be combined with it to prevent this tendency to dry the milk, without destroying its other properties, and if any person acquainted with the nature of medicine would prescribe a remedy for this defect, and insert it in some of your next numbers, he would be conferring a great boon on farmers in general, and the communication would be thankfully received by

A WELSH FARMER.

May 25th. 1840.

ON THE CULTIVATION OF POOR CLAY LANDS.

It is universally confessed by practical men that no class of soils cultivated by the farmer yield so small a return for the labour expended, and are so difficult and precarious to manage, as the thin clay lands on a very stiff and retentive bottom, which much abound in many parts of the kingdom. Light sands and chalks are very similar in value, but much more pleasure is derived from their cultivation by means of green crops and feeding by sheep, and more profit is obtained from their being used in that way, and in subservience to the other lands on the farm. Agricultural writers, who had no guides but theory and want of experience, have only exposed their ignorance in asserting that all clay lands may be cultivated by means of green crops and leguminous plants; as it is well ascertained that no means known to us will reduce these stiff soils to a state fit to be planted with these crops, and in which they would vegetate and grow. These soils vary in value from 8s. to 16s. an acre, and may be divided into two kinds,—a hard black soil, and often red like brick, on a wet clay bottom, and a soft black soil on a bottom equally wet and retentive. Any attempts to produce green crops on such soils are wholly beyond the question, and beans, pease, and vetches have been recommended as capable of enabling the farmer to dispense with the fallowing of the lands for one year, by which process one crop is lost, with the rent and expense of labour incurred.

But experience has shown that these crops may defer, but cannot take the place of, a summer fallow; spring vetches may be eaten on the ground, and a partial fallow may be afterwards effected, but it will be very imperfect, and the land should be ready for sowing with wheat by the time the vetches are consumed. The quality of the land will very seldom afford a decent crop of the herbaceous green plants, the manuring obtained would be very inconsiderable, and even in the dry season of summer, the feeding of sheep on such soils would be ineligible and detrimental. The wetness of the lands in the spring and autumn, and the late harvests in many places where such soils very much abound, wholly exclude any working of the land before sowing the crops of beans and pease, which require a spring tilth at an earlier period than the nature of the soil will allow; and the greater difficulty remains in applying the manure to the land in a suitable state of tilth and pulverisation. These crops may be sown broad-cast, but then they rank as a corn crop, or they may be drilled and hoed, and then they hold nearly the same position, but on such soils the process of drilling any crops in the spring is very precarious, and in most cases a physical impossibility. The clays on which drilled crops are grown are loamy soils, to admit of that process; but even on good wheat clays, it has been found impossible to substitute these crops for summer fallowing, with equal advantages of crops, and in the state of the land. On the soils mentioned, there need be no hesitation in asserting that no process or means is known by which the land can be prepared for these crops, and the dung applied so as to produce equal effects with a fallowing, either in the state of the land, or in the value of the crops of a continued rotation; no spring working or summer scuffling will reduce and pulverize such soils, which often require the whole summer for that purpose, and to many of

these lands the plants themselves are physically inappropriate as a crop. Even on the best lands they are used as chance crops, in order to defer the fallowing process when the land is in good condition, as the early period of sowing prevents the cultivation that can be effected from becoming a substitute for fallowing, either by green crops or by the summer process. It remains to be seen what difference will be made in the nature and texture of these soils by the modern system of furrow draining: whether it will render them more loose and friable, and more fitted for green plants, or only make them more accessible at different seasons, and easier managed for the usual crop. Some loamy clays may be converted into green crop lands from a previous near alliance, but the stiff clays now mentioned are probably beyond that possibility.

Summer fallowing being indispensable for the working and pulverization of clays, and wheat being found the most profitable crop after fallow, even in the very small quantities that can be obtained, various rotations have been followed and published, including and stating the crops that are most suitable after the fallowing process. The boasted four years course is too short for any soils, and the same plants recur too frequently, although it is very commonly followed on the poor clays now mentioned in the form of—1. Fallow. 2. Wheat. 3. Clover and seeds, cut or pastured. 4. Oats. The grass seeds very frequently "miss," in farmers' language, but the predominant love of corn crops will not allow a prolongation of the term. The oat crop is also very indifferent, because there is no vegetable sward or freshness to yield nourishment to the plants by subsequent decomposition. An improvement has been suggested, by sowing peas, beans, and vetches on the wheat stubble, and thus sowing clovers only once in eight years on the fields alternately. I perceive that I understand the word "rotation" in a different sense from most writers—they apply it to the period when the same plant, cereal, leguminous, or cruciform, is sown on the land under the same preparation, and with manure applied in the same manner, and that the plants may be used in the intervals in a different way, without terminating the rotation; I have been accustomed to understand it as being terminated, when the same plant is sown by the same preparation, and that all the intermediate crops wholly consist of different plants, without any manure being applied. I use it in this sense in the following remarks.

The many rotations that have been published do very few of them apply to the poor clays now mentioned, for they mostly suppose a manuring for beans, and crops to be eaten on the ground by sheep; and some even suppose turnips, which soils belong entirely to another denomination of land. Barley is proposed to be sown after fallows, but on poor hard clays the plant is wholly unfit, and repeated trials have confirmed wheat as the most profitable. The growth of winter and spring vetches requires a loamy softness of composition in the land; they seldom succeed on these hard sterile clays, and when they fail and plant thin, the land is rendered fouler, and no benefit can be obtained from the feeding by sheep, unless the materials of feeding, or the crops themselves, can be obtained, which can only be accomplished by putting the land into good condition by previous fallowing, cleaning, and manuring. Peas are similar in nature to vetches, and the benefits that both crops confer on light dry lands, by

shading, smothering, and manuring, which are certainly not small, have, upon trials, been found incapable of being realized under totally different circumstances in the lands on which they are used. On such soils the crops have been found not worth seed and labour, besides rendering the land much fouler, unless previously in good condition; and beans have been found equally unproductive. Broadcast crops of these plants seldom fail in fostering abundance of weeds, and any partial benefit from hoeing or weeding is a very insufficient check, and produces no effect on the stubborn surface of the soil. The confining of sheep on these bare wet soils to consume clover, vetches, or any crop with a half arable surface, or swarded, would be highly injurious and detrimental; and besides the crop of artificial grasses is mostly so scanty as to yield a very light crop of hay, and sometimes a bare pasturage for one sheep on an acre, and much less a crop to feed a flock for the purpose of manuring the land. In many of the rotations that have been published, two and sometimes three crops of wheat occur in a course of six and eight years—a system of cropping that must suppose very extravagant manuring, and also land of good quality, a ready command of animal manure, either in a putrescent form, or by feeding the crops on the land. Where such means can be commanded, the rotation is unobjectionable, and the requisite skill is best shown in adapting the course of cropping to the support that is available. No doubt can exist that a crop of green herbaceous food, to be consumed on the land at some period between the processes of fallowing, will afford great assistance to the land in producing the future crops; but it must be known that the crops themselves can be obtained, and that other circumstances will allow the full and unqualified benefit. If winter vetches could be produced on these thin soils, the crop could not be wholly consumed before the middle or end of May, and any fallowing effected after that time would be very imperfect, for in general management, a very effectual part of the process is accomplished before that time, and the advantages of early working on stiff clays are well known to every cultivator. On some drier clays, spring vetches eaten on the ground, afford a good preparation for wheat on one furrow: but it is only a catch crop, and delays, but does not dispense with fallowing. In the rotations that have been published in this Magazine, it would be desirable for the writers to state the preparation of the land for beans, the season of sowing, and the mode of applying the manure. It is evident that the lands are much superior in quality to those I have mentioned, both from the crops produced and the repetitions.

Thin clay soils much abound in Durham and Northumberland, in the southern counties, and in many parts of the kingdom. A long practice in cultivating them where the fallows amounted to 150 acres yearly, has induced me to make some remarks on the rotations that might be adopted with most advantage, and on the general culture of that denomination of lands. These soils are generally, but not always, found in situations inland, and distant from extraneous sources of manure; the quantity of turnip land is small or none, and the scanty produce obtained from the lands afford a very limited supply of dung, from the want of green crops and the animal manures that accompany them. Lands badly fed cannot withstand constant cropping, even with the plants

that are found most suitable; the soil must have rest: and since animal manures and putrescent matters cannot be obtained, it remains to produce vegetable matter in the soil itself, which may afford nourishment for future crops, and, at the same time yield a profit during the production. The four year's course soon exhausts these thin soils, manure is only applied once during the rotation, and scantily from want of the materials. In the absence of the knowledge of any crop that would afford to such soils an intermediate support between the fallowings, the whole benefit rests on that process, and wheat has been confirmed by experience as the most profitable and most suitable to be sown on the land prepared in that way. The subsequent crops may be stated as follows:—

Years.	1	Fallow.
	2	Wheat.
	3	Seeds, mown or pastured.
	4	Pasture.
	5	Beans, peas, and tares.
	6	Oats.

or,

Years.	1	Fallow.
	2	Wheat.
	3	Seeds, mown or pastured.
	4	Pasture.
	5	Pasture.
	6	Oats, peas, and tares.

or in a five years course,

Years.	1	Fallow.
	2	Wheat.
	3	Seeds, mown or pastured.
	4	Pasture.
	5	Oats, peas, and tares.

The first rotation may suit the class I have mentioned as being of a softer texture, where leguminous crops have a chance probably of partial success, and the latter course will be more suitable to those of a harder nature, where the chance would be less.

In fallowing these soils of the harder class, the texture should be broken, and the pulverization effected in the early part of the season by mechanical force of the roll and the plough, repeatedly applied; the harrow will not avail much till summer rains have softened the cohesion. On the black and softer kinds, the lands may lay during the early heats and droughts in a rough unbroken state, till they dissolve naturally in the latter part of the season; for if they were reduced by force in the first months, they would be in too fine a state in October for a bed for wheat, and be apt to throw out the plants during winter. With brick-like soils, the case is very different, for they cannot be too much reduced, and there are seldom any weeds in either kinds to disturb the process. Drilling of wheat can seldom be practised: the wetness of the lands, and the very awkward form of the ridges, lying in crooked, unequal, and serpentine breadths, present a great obstacle to any attempt of drilling by machinery; and the precarious season on such lands renders dispatch absolutely necessary in committing the seed to the earth in the best possible form. Ribbing has been practised, but has not been attended with any result, except in a few instances where tall weeds abound to be pulled by hand. The grass seeds should be sown on these hard lands on a pulverized surface produced in the spring by proper harrows, and covered by a single application of the same instruments, and finished by a heavy rolling. It is a very general opinion that grasses will not grow on these lands, and for the best of all reasons, be-

cause they are not sown ; but if the land be properly prepared, a crop of hay and pasturage may be obtained, which will much improve the latter crops. The following list of seeds may be found generally applicable :—

- ½ bushel of perennial ray grass.
- ½ do. of cocksfoot.
- 6 lbs. of dogstail.
- 4 of catstail.
- 4 of meadowfescue.
- 6 of red clover.
- 4 of white clover.

The dogstail will be found a most useful grass on these hard sterile clays, and it ever affords a very grateful herbage ; and pasturage of two and three years will afford a vegetable sward and keep for sheep. The following crops of beans, peas, tares and oats, may be regulated at pleasure, as the nature of the soil and circumstances direct ; but generally speaking, leguminous crops never failed in my observation to render the lands much fouler, as no possibility exists of drilling any spring crops on such lands, except it may be in a particular season of rare and uncertain occurrence, and hoeing and scuffling would be of no avail. Pasture will improve the land, and keep it cleaner ; but if the grasses should partially fail, arable culture may be the sooner adopted. On some drier sorts, spring tares might be eaten on the ground, which would greatly improve the chance of the oatcrop, although that circumstance would depend on the season being wet or dry and if the tares can be produced, which rarely happens on the poorer clays.

In looking at the rotations that have been lately published in this Magazine, I observe that the land is fallowed after the winter vetches are consumed. I have often thought that an imperfect fallowing can be performed on any land after a winter crop, except in some particular turnip soils, and that the state of the soil for the reception of seed is much inferior to the regular process of working after a winter furrow. But as these rotations evidently apply to loamy clays of good quality, no comparison exists ; for the land must possess both these properties, and also a dry and early climate, before winter vetches can be produced and eaten on the ground, and the bean crop be dunged, drilled, or hoed. On clay lands of the best quality, and on which green crops cannot be introduced, it has been found ineligible to postpone the fallowing process beyond six years or eight at the utmost, and the green and grain crops are used in alternation during that period. The old rotation is yet much used on good clays :—1 Fallow, 2 Wheat, 3 Seeds, 4 Oats, 5 Beans, drilled and manured ; 6 Wheat : and also, 1 Fallow, 2 Wheat, 3 Beans, 4 Barley, 5 Tares, 6 Barley, 7 Clover, 8 Beans, and 9 Wheat ; and another, 1 Fallow, 2 Wheat, 3 Beans, drilled and hoed, 4 Barley, 5 Clover manured, 6 Oats, 7 Beans, 8 Wheat. The clover crop is too distant from the fallowing of the land, which presumes the cleanest and most pulverised state of the soil to suit the small and tender seeds of the papilionaceous plants. These and similar rotations, suppose lands of the first quality, and in eligible situations ; the soils I have mentioned are of the most inferior order that are cultivated, and which cannot keep animal stock, to raise manures from want of green crops, and which are unfit for the production and use of the herbaceous plants that are the only known substitutes, except in a very partial degree. It remains to be seen what alteration the modern system of furrow draining (if it ever be performed, as it might have been all done by this time,) may effect in fitting

these soils for green plants, leguminous or cruciform, and if the subtraction of water will render the lands capable of producing them, and for the introduction of sheep to consume them. This essential point is never mentioned in any details we read of the advantages, and the increase of grain produce, derived from draining. J. D.
June 20, 1840.

The disinclination of the farmers to co-operate for any purpose involving their common interest, has long been matter of regret to the most intelligent of that body, and has been frequently commented upon by us. When, therefore, a disposition is manifested to unite in carrying out any legitimate object of mutual interest, it should be encouraged as much as possible.

We observed, some time since, in the *Norwich Mercury*, a notice of a suggestion made at the Midford and Launditch Agricultural Association, by Sir C. Clarke, who takes a great interest in everything connected with agriculture, for the formation of a Benevolent Society for the relief of the "Widows and Orphans of farmers."

We have not had an opportunity of seeing a prospectus or detailed statement of the plan, but we find the following description of it in the *Norwich Mercury* :—

"The leading features of the constitution of the Society are these :—

"The occupation of 200 acres of land, or a rental of 200*l.* per annum, or being the proprietor of 100 acres, with an annual subscription of 1*l.* shall constitute a member. The election to be by ballot (after the 30th of September, 1840), by a majority of at least three-fourths of the members present at a quarterly meeting of the Society, and having been proposed at a previous meeting. That the payment of 10*l.* or an annual subscription of 1*l.* for twenty years, shall constitute the subscriber a member for life. That the nobility, gentry, and clergy, be honorary members, by a donation or an annual subscription. If the subscription remains unpaid one month after notice from the secretary, the defaulter shall forfeit all interest in, and cease to be a member, unless a fine of five shillings, together with the annual subscription, be paid for re-admission, within the space of twenty-one days. The management of the fund to be vested in the life and annual subscribers. The committee to be chosen annually ; to consist of nineteen members, of whom not more than fourteen can have been upon the committee of the former year, and not less than five to form a quorum. No relief to be rendered until two years' subscriptions are paid, in addition to donations received, except in cases of urgent and unforeseen distress, when the committee are to have the power of issuing sums on their own authority, not exceeding 10*l.*, to the widows and orphans of deceased members. The relief to be in the form of donation, and never that of an annuity, even for a limited number of years ; and on the application of not less than seven members the secretary shall be empowered to convene a general meeting of the society within one month from the date of such requisition."

The fact of such a proposition having been favourably received, and having obtained support, is highly gratifying to us as an indication of a dis-

position on the part of the farmers to pursue a course long since adopted by other classes of the community. In considering the matter, however, it naturally occurs to us to inquire, whether the plan proposed is the most beneficial. And here we would wish it to be most especially understood, that in the comparison we are about to make, we do not wish in the slightest degree to prejudice the society to which we are now directing attention. Possessing no other information than that which is contained in the above extract from the *Norwich Mercury*, we are unacquainted with the amount of benefit which the projectors of this society expect to be enabled to confer, by means of the funds which may be subscribed. In order, therefore, to enable those who are directing their attention to the society to make a comparative estimate of the advantages which may be derived from the outlay of one pound annually, as a subscription to this society, or if laid out with another institution expressly dedicated to the interest of the farmers, we beg attention to the following statement:—

As we before stated, we will not speculate upon the probable advantages offered by the first-mentioned society, we will only state, as regards the latter, the "Farmers' Fire and Life Insurance Institution," that the payment of one pound annually for life, by a man 26 years old, will give his widow or children a positive and indefeasible claim for 50*l.* at his decease, supposing that to take place even in the very next year. The payment of the same sum annually, by a man 48 years old, will also entitle his widow or children to 25*l.* at his demise. Should a party be inclined to pay one-half of the premium, and let the other half remain at interest at 5 per cent., to be deducted from his account at his decease, a payment of one pound per annum, with interest at 5 per cent. for another pound, by a man 26 years old, will entitle his widow or family to 100*l.* less the one pound remaining at interest, even should he die the very next year. The adoption of the same plan would give 50*l.* to the representatives of a man aged 48.

Here it should be observed, that neither the amount nor the payment of it depend upon the will of any individual. The representatives of the insured have a positive *right* to the sums named. It is not in the shape of a charitable contribution or donation; it is the result of a contract made by him, and for which his representatives have as clear a legal remedy as for any other purchase he may have made in the way of business.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—Allow me, through the medium of your valuable paper, to make a few remarks on a letter which appeared in the *Mark Lane Express* for June 1st on Cottage Allotments, signed "K," whose views in some points accord with mine (as contained in a former letter to you, on the same subject,) but in others I beg to differ with him, as I think he does not duly appreciate the advan-

tages that ought to be derived from a plan so noble in its nature, and elegant in its design; but I may be wrong also, therefore I will state a few facts, simple in themselves, and leave them for your numerous readers to judge, and to give them that due attention which they need.

Your correspondent recommends, "one-fourth of an acre as the quantity of land best adapted to carry out the Allotment System most advantageously," and further on he says "and best calculated to prevent his encroaching upon that portion of time which should be appropriated to the discharge of his duties to his master."—What advantages will be derived from allotting 1200 square yards to a labourer, with the intent to improve his condition? Not any but keeping him a few evenings from his wife and family, or spending an hour with some fellow friend talking over the affairs of the village. Will he have sufficient corn and potatoes to feed a pig? No. Then what advantage will a pig be to him if he has nothing to feed it with? He will have to spend a shilling or two out of his daily wages to endeavour to support it—and is this improving his condition? Then suppose he sows half his allotment with wheat, and the produce is four strikes; and he plants the other half with potatoes, reserving a portion for cabbages, onions, carrots &c., and he has the rent to pay for the land; where is the improvement in the condition of the labourer either physical or intellectual? He then says "about two and a half acres of land to three strong unemployed boys will be found sufficient, provided the man has regular employment." Would a father trust the tillage of his land to his "three strong unemployed boys?" No—I say he would not, or at least he ought not; if he did, he would be liable to suffer from the effects of idleness and deceit which would cause that cultivation which is unfit for Cottage Allotments instead of that which is so desirable, yea, even necessary, viz. the proper use of the spade. Further on he says, "the straw should be carefully preserved for manure, this in addition to what is collected on the roads by the children, will contribute towards the manuring of more than one-third of his land." Then what quantity of straw will the tenant have for manure? and what quantity will twenty or thirty children collect off the roads? and does not more than one-third of the land want manuring each year? I ask where will the tenant get manure sufficient for the management of his land? On distributing prizes I shall speak of that presently.

Having thus proceeded far, a question naturally presents itself, viz., what advantages should accrue from Cottage Allotments, the best manner of cultivating such allotments, and the quantity of land necessary, so as to improve his condition, physical, moral, and intellectual? The advantages ought to be such, and so managed, that shall improve him in the three conditions just named. First, by allotting a sufficient quantity of land to endeavour to improve his physical condition. Secondly, which by having sufficient necessities of life would remove all outward temptations to steal or defraud his neighbours, and thus tend to increase his morality, and eventually improve his moral condition; and thirdly, by improving his physical and moral condition, he will see the necessity of improving his intellectual. Of the manner of cultivating, and the quantity I recommend to be allotted, (see my first letter in your paper for April 27th 1840).

In any one devising a system, it is rational and natural to inquire how far it will affect self. Your correspondent "K" seemed to have a little regard

for self when he says, "and best calculated to prevent his encroaching upon that portion of time which should be appropriated to the discharge of his duties to his master." The Farmer in proposing a plan of Cottage Allotments looks around him and says, "if we let these people have more land than will grow only a few potatoes and cabbages for themselves, where will our labourers come from?" we shall have either to diminish our farms, or assist in working ourselves; the former is painful to ourselves, inasmuch as they think it will diminish their dignity, while the latter will more so, besides being much more painful to the system generally. But let them not rest here, but look forward. What will be the condition of the labourer ten, twenty, or thirty years hence? we have steam applied to almost every kind of machinery; we have railroads, trains of carriages hurled on by the same power—and this wonderful vapour is not only applied to the various powers of manufacturing instruments of different kinds for agriculture, but is even applied to work those instruments itself; hence steam ploughs, and thrashing machines &c.—We also have instruments invented to be moved by the horse; as the hay-making machine &c., and several other instruments, all tending to diminish the less necessity for manual labour. Mechanics—what will then be their employment? It is a great evil in the present day, to judge of any system by the effects it produces, immediately, or soon after it comes into operation; but to improve the condition of the Poor, it must be done generally, and so combined that it shall not only do good in the present day, but that its beneficial effects shall increase from generation to generation. What effects do railroads produce on the post-houses, and what on the labourer? They ruin the former, while, for a certain time they are of benefit to the labourer, in causing an increased demand for labour. What effect does, and will, steam produce on the welfare of the Mechanics? It will ruin them, while they will be obliged to become labourers; labourers will be in excess; our work-houses will want enlarging; more will want erecting; and there will be a general stagnation in the country. Depredations of all kinds will be committed, and nothing but sin and folly will reign among the people. Then it behoves the land-owners and farmers to look at and prevent this impending calamity; and this I can conceive may be most happily achieved, by apportioning a quantity of land to the tenant that shall exalt his station. We, as a body of farmers, must have less land, managing better what we have, and letting to our humble brethren the remainder. Geological researches inform us, a quantity of land in this and foreign countries, remains open for cultivation; in our country we must diminish our pasture land in order to favour the objects of this system, and agriculture in general. To make foreign lands of benefit to our country, we must endeavour to promote emigration, in order to lay open a wider field for cultivation in our native land; while at the same time we are causing the numbers of our population to diminish. But all this cannot be done without the assistance of the labourer or poor; they must endeavour to decrease the number of their families, by checking those passions which is the inevitable cause of such fruit following. These three plans, the allotment system, emigration, and a decrease of the animal passions, will inevitably improve the condition of the poor; but I would not wish it to be understood that the poor should roam, and manage as they choose; no, far from it: I would still have them under the

restriction of a scrutinizing committee, punishing where deviation occurred, and rewarding where emulation is due;—but a question arises, what is to be understood by *rewards*? (This brings me to notice the subject of awarding prizes.) Rewards are of several kinds, but I shall only notice two; one kind of reward is, where a medal, or some other article is given for some good action performed, this may be called a prize; another is where we, by teaching the poor labourer the theory of farming, and instructing him in the various branches of it, and improve his intellect; this may be called, the reward of pleasure arising from a cultivated intellect; the latter reward appears to me to promise more lasting benefit, the former, while it indulges a spirit of emulation and increases a covetous desire, is soon forgot, while the latter imparts a lasting pleasure, I may say indescribable. Then instead of prizes I would say institute a course of lectures to be given in the dark season of the year, deducting one hour from the daily labour of the labourer, deducting at the same time, his wages in proportion: but an objection may be urged against lectures being given to the labouring poor an account of what I have stated in my last letter to you, namely, that after the exhaustion of the physical power by hard labour all the day, that it was too much to exhaust the nervous power as well. In answer I ask in what way have I provided against this, to diminish the labour one hour. And in addition I would recommend that the lectures should be plain and easy, destitute of those arguments which require an active mind to follow them through all its bearings. But it may be said in reply, is not even this exhaustion? is not this cultivating the mind? I say certainly it is; but is there not a difference between educating the intellect of a child, in driving as it were learning into it, and stating facts simple in their nature, to an experienced, and a mind more easily and more capable of receiving instruction, and more especially a subject in which the labourer would take great delight? I leave these facts to a discerning public to judge of their merits, and asking pardon infringing so much on the pages of your valuable Journal, I remain Sir, your obedient servant,

A FRIEND TO THE POOR.

*Sutton on Trent, Nottinghamshire,
June 5th.*

SHEEP BREEDING.

My present letter will be as much made up of shreds and patches from others' productions, that it will be but the fillet wherewith to bind together the flowers of other men's abilities, and therefore will not puzzle your compositor with making endless quotations, but at once thankfully acknowledge the great helps I am receiving from those who have already so liquidly and forcibly set forth what I am humbly at a distance trying to imitate. Premising—I have heard it objected that "Practical" uses too many technical phrases for ordinary readers. I am not aware of having done so; I give English farmers credit for understanding English language.

It has been propounded that, when we have once got a flock or herd of animals to our mind, they require only to be kept together, without any skill exerted in selection to produce an offspring in no respect degenerating from the so satisfactory stock. Against such doctrines I strongly protest. Far from thinking it possible by such an inattentive mode of proceeding to perpetuate, or even to retain, the valuable properties so acquired,

I am of opinion that from this very want of attention the stock has been both greatly jeopardized and misunderstood, as shown in a want of constitutional hardihood externally indicated by co-existent defective formation in the parts which denote the presence or absence of that important though disregarded requisite.

Fashion, like the fabled Sirens, often leads men astray, and to the magic of a name vital considerations have been sacrificed. Just now a cross holding a name of the Leicester, with a spice of the Gloucester or other fancy pattern forms, with the unthinking, the talisman by which every difficulty of land, climate, and circumstance is to be removed, and every inconvenience avoided. And when a breeder has obtained a flock so constituted, he concludes he has done all that is required, and is, *ab initio*, an accomplished flock-master. This is rote, not science.

Sir John Sebright observes, the existence of a perfect animal is an hypothesis; he cannot admit—therefore, in the animals got together from the four winds of the earth, whose present adventitious appearance constitutes their main recommendation, there must have previously existed defects, though latent for the moment, but which will necessarily again obtrude themselves. As the tree needs pruning—as the garden wants weeding—so does the breeding animal require selection!

In an highly improved breed of animals (sheep) there will exist a constant struggle between the desirable and undesirable qualities, the latter of which being constitutional, and the former, in a degree, or for a time, artificial, Nature will, under mismanagement, or if even left to herself, seek to revert back to her former level, to obviate which, “in and in” breeding, under judicious treatment, is our main defence. May I instance what I mean?

Mr. Marshall (an unwilling witness) says Mr. Bakewell's bull, D, is a fine animal, and is a striking proof of the vulgar error that breeding in and in weakens the breed; D was the son of Two-penny, out of a daughter and sister of the same celebrated bull, she being the produce of his own dam; nevertheless D is the sire of Shakspeare by another daughter of the same bull, and is probably the most robust individual of the long-horned breed—while D himself, at the age of twelve or thirteen, is more active and higher mettled than bulls in general are at three or four years old. Here then is an animal from the closest affinity of blood, that at twelve or thirteen years old, surpasses in stamina and vivacity other animals of three or four years old procured from frequent crossings. Therefore, where there exists in animals great constitutional vigour, and the important points of excellence preponderating very considerably in both parents, surely the system of in-breeding may be adopted with impunity, watchful attention being given to the detection and expulsion of any deteriorating symptoms, and like remarks will justly apply to other kinds of stock.

Mr. Bakewell being dissatisfied with the results of a continual infusion of new blood in his pigs, adopted the plan of using but one and the same boar, which boar eventually became the father of all his swine, the consequence was, the breed, so far from being worn out or weakened thereby, has been highly improved in every good quality. Dr. Johnson remarks that there are no weak or deformed people among the Indians, and with his usual sagacity assigns the reason, which is, that the hardship of their lives as hunters and fishers does not allow weak or diseased children to grow up.

Neither should we allow weak or diseased stock to perpetuate their imbecility. Yet such is the lack of knowledge that not a few of us prize our males for those features which are purely feminine, forgetful that while we are admiring a fine head in the male we are but glozing over disease and infirmity in his constitution.

Those disapprovers of close breeding who have but imperfectly matured their ideas on the subject, with a good tempered air of triumph, enquire whether the improved race of sheep can be perpetuated in its excellence otherwise than by the vigilant exercise of a peculiar management; or whether they may now be left to the process which Nature would pursue without soon exhibiting that they are as capable of becoming worse as they originally were of improvement? I look the enquiry in the face and say,—the improved race of sheep does require incessant vigilance and peculiar treatment; and it is precisely for this careful and peculiar mode of breeding I am now contending, as I am quite sure that if left to the process which Nature would pursue (promiscuous intercourse) we should soon slide back to the kind of flocks our Roman conquerors left us, more like goats than sheep. What I advocate in theory and admire in practice, is the scientific observance of and waiting upon Nature, to train her willingness to melioration, and to prune out her aberrancy.

Mr. Bakewell, to whom all England is indebted for his numerous invaluable discoveries in agriculture, and for *creating a new breed of cattle*, is an honourable instance of what I mean. He waited, not for chance to throw in his way animals fitted for his purpose, he made excursions to various parts of the kingdom, inspected the different breeds of cattle and sheep, ascertaining those which were best of their kinds and most valuable for his purpose. These he purchased wherever they could be found, and this selection was the original stock from which he propagated his own. In the animals thus selected it is to be presumed that much excellence must have existed, yet to improve upon that best stock, and amalgamate it into one blood was a merit at that time peculiar to himself; and as he approximated to the desired point, his animals (sheep especially) evincing so much superiority in wool, symmetry, and constitutional excellence, that he certainly could not, with propriety, use any stock but his own; for having attained this elevated position of excellence, he thereby became and continued an in-and-in breeder, for evidently any other course would have been wilfully and ridiculously to court retrogradation; and having so bred for a great number of years he thereby obtained a new and superior race of sheep, from which he so carefully weeded defects that at last he could give such a character and warranty to his flock as no contemporary could venture to do.

And those few flock masters who have judiciously possessed themselves of his pure breed, and kept it uncorrupted from meaner blood, have now the finest and healthiest sheep in England, with an uninterrupted pedigree and qualification for nearly half a century.

Thus I have arrived at the end, not of the subject, but of my fourth long letter. I will now pause for correction from some of your more experienced and talented correspondents, and then, by permission, will trouble you with the description of what I consider a good sheep, and suggest how to procure, sustain, and perpetuate so desirable a breed.

I am, your's, &c.,

PRACTICAL.

ON THE COMPARATIVE MERITS
OF PLOUGHS.*Pembrokeshire, June 3.*

SIR,—Having read in your magazine an account of Messrs. Handley and Pusey's experiments on the comparative draught of ploughs, and seeing they plainly prove that the same work can be done as easily, and well, by two horses in one kind of plough, as by three in another—a fact so important to farmers, that I have been induced to make a few trials myself, in order to ascertain the draught of the ploughs commonly used in this county, compared with those spoken of by Mr. Pusey, and if you think the results of them worthy of your magazine, they are before you. The ploughs used here by the larger farmers are of two kinds, one having the improved Scotch mould-board, which gives it a narrow breast, and curves out quietly behind; the other is something fuller in the breast, and the mould-board has less of the hollow curve. The small farmers almost universally employ a very light, but clumsily-built instrument, called the old Welsh plough; almost the only iron about it is the coulter, a very narrow share, and a band forming its extremely long solepiece.

Before I commenced the trials, I procured one of Mr. Cottam's gauges, which has a piston that works in a cylinder, filled with oil, attached to the index, which imposes so powerful a check on the rapidity of its vibrations, that the eye is enabled to mark its movements with very tolerable accuracy, which, with any I have seen before, was out of the question; and also, one of Hart's ploughs, as a sort of standard, its draught having been proved before by Mr. Pusey. Besides this, the ploughs were two light iron ones, with the narrow breast, and expanding mould-boards, weighing about 12 st. each. A wooden one, somewhat fuller in the breast, and less of the expanding curve behind to the mould-board, weight 10 st.; and also an old Welsh plough, weighing 6½ st. The ground chosen was an outen stable, light, but hard, from the dry weather, the furrow 5 in. by 9 in.; the draught of Hart's was 13 st., of the wooden one 17 st., of the iron ones 19 st. and 20 st., and of the old Welsh 20 st. I then had Hart's wheel fitted to the wooden plough, which, on the same ground, it reduced to 14 st. From this trial it was evident, that all our ploughs are of heavy draught compared with Hart's; but I think it owes this lightness rather to its open mould-board, which so greatly reduces the surface exposed to friction, than to its full breast, which must push off the furrow slice at once, just at the point where it is severed by the coulter and share, and where, of course, its resistance must be greatest, and leaves very little for the hind part of the mould-board to do, and this little, for want of a curve outwards, it does very imperfectly, as it leaves the furrow standing too much on its edge, whereby the surface grass and weeds are not destroyed; and this was still more evident in the work of the old Welsh plough, which has a still straiter mould-board; while the Scotch mould-board, by means of its expanding curve behind, threw it quite on its back; that the full breast adds to its working draught in Hart's, is also apparent, from the distinction Mr. Pusey has made between that and its surface draught; and still more so in the old Welsh plough, where the surface draught was 4 st., and the working 20 st. Of the advantage of a wheel I think there can be no question, for, besides keeping the plough constantly to the same

depth, it seems always materially to lighten its draught; and I think the reason is plain, for, when at work, much of the surface draught must be transferred to the wheel, from its resisting the tendency the share has to draw the plough downwards.

There is another point I should very much like to see fairly determined, which is,—at which distance from the plough is the best place for the horses? From several trials I have made, I am inclined to think there is no difference in the draught of the plough, but there may be much in the power of the horses. I cannot agree with Mr. Pusey about the value of an uplifting force, for I imagine the share acts merely as a wedge, and that any producible uplifting power would go a very little way towards overcoming the resistance of the soil upon which it acts, and that little must be counteracted by the ploughman, or the share would come to the surface, and it cannot be advantageous to bring two antagonizing forces into operation together. I intend to try if I cannot improve the work of Hart's plough by changing its mould-board for one of the same dimensions, but with the hollow curve, which will give it a narrow breast, and, I think, throw the furrow slice more on its back; and as the weight of a plough seems so greatly to effect its draught, I have sent to Mr. Ransome for the irons of his F. F. plough, to which I propose to adjust a wooden beam and handles, and also one of Hart's wheels, whose plough I then expect it will equal in lightness, and beat in the quality of its work. If it prove so, and you think my communications worth insertion, you shall hear from me again.—Your obedient servant,
L. M.

It has been a matter of dispute for some time whether the preference should be bestowed on oxen or horses as beasts of draught; and both sides have contested the point with too much prejudice, and sometimes with too much animosity; this is one reason why the question has never yet been decided, and why no positive results have yet been arrived at on the subject.

The preference must certainly be given to horses on the following considerations:

They are capable of all kinds of agricultural labour, they adapt themselves to every road, and to every degree of temperature. Where horses are kept there is no occasion to select the particular kind of labour to which they may be applied, they may be employed in any work which presents itself, and attached to all implements. They perform all kinds of work very expeditiously, and are capable of sustaining their speed for a considerable length of time; consequently the conductors are kept fuller employed while working with horses, than when working with oxen. Although less steady at heavy draught than oxen, the rapidity of their motion and their spirit enables them to overcome all obstacles of short duration, which would frequently stop a team of oxen.

Oxen, on the contrary, have the following advantages in their favour:—

They can execute most of the agricultural operations, ploughing, draught, &c., equally as well as the horse, and when well fed, are capable of enduring almost as much fatigue. Many persons consider that they are more useful in ploughing in corn than horses.

Their keep is much less expensive. The original price of an ox is generally far below that of a horse;

their harness also is much less costly; their food is much cheaper.

Oxen so far from diminishing in value when they are well fed and not overworked, frequently become more valuable, and on being sold often fetch more than their original price, thus almost paying the interest on their capital; whereas horses decline in value as they grow older, until they are worth little more than their skins, and the capital expended on them is thus completely absorbed. Oxen are also less liable to accidents and disease.

They require less cleaning and attention; a cowherd can take care of thirty oxen, when other men work with them alternately.

Lastly, they produce a greater quantity of dung, and the manure derived from them is generally more useful than that which is obtained from horses.

We shall be able clearly to demonstrate that which must already be apparent, that even that portion of agricultural labour which can be properly executed by means of oxen, will not be executed so cheaply by them as by horses. If all the operations on a farm were of such a nature as to be easily performed by oxen, these animals only ought to be made use of. Although the operation of harrowing is far better executed by means of horses than by oxen, yet this does not, in my opinion, form a sufficient consideration to induce the adoption of the former. But in most farms there are many operations which oxen are still less calculated for, or at least which they perform exceedingly slowly. This would be a sufficient motive for keeping a certain number of horses, regulated of course by the amount and extent of these operations.—*Von Thair.*

ANIMAL OIL FROM WOOL USED AS A MANURE.

TO THE EDITORS OF THE LEEDS MERCURY.

Gentlemen,—Observing in your paper of last week an extract taken from the *Mechanics' Magazine*, relative to a series of experiments made in France, to ascertain the value of oil arising from the washing of sheep's wool, I beg to observe that in this county, as well as in Cornwall, the wool is not washed previous to clipping, as in the upper counties, consequently a very much larger proportion of animal oil, or what is termed *yolk* in this neighbourhood, passes off in the manufacturers' wash pans, intermixed with soap suds, and where business is carried on to a great extent, an immense quantity can be obtained, varying I should say from 10 to 20 and upwards to 100 hogsheds per week. The benefit arising from this article as a manure, properly applied, is incalculable; the writer of this has been making the experiment within the last eight or ten months, by applying it on a large quantity of earth collected from different parts of the estate, and after properly mixing and turning it over once or twice, it is thrown up in ridged heaps to carry off the rain water; this spring we have carted out sufficient to cover over from ten to fifteen acres of ground, laid down to grass, and I feel confident that it is equal, if not superior to any farm yard compost that can be obtained in the usual way.

I state these observations in consequence of seeing the subject broached in your valuable paper; and if it leads the manufacturers in the north of England, who may be agriculturists as well, to try the experiment, it may, I consider, act as a stimulant to those who are more largely interested; and it may be also the means of inducing the manufacturers to offer for sale, for the benefit of the community at large, what hitherto has been deemed as useless by them.

Gentlemen, your most obedient servant,
Ashburton, Devon, 11th May 1840. S. T., Jun.

A COMMENT ON FORMER COMMUNICATIONS.

TO THE SECRETARY OF "THE LABOURER'S FRIEND SOCIETY."

SIR,—The last number of your Magazine affords evidence of the vast utility of the allotment system, both affirmatively and negatively. From it I shall, in a running commentary, endeavour to shew how much is yet to be done, and how perfectly secure the course of further improvement is to the labouring classes. The materials alluded to in the April number shall be those only to which I shall at present invite attention, with such observations as appear to me arising naturally out of them. Commencing with Mr. Acland's report respecting Sussex, and taking for granted what he states, it appears that the population is 300,000, and the number of acres 903,000, or three acres to a man. The estimated number of agricultural labourers, 20,000. The condition of the labourers such as to give an average of twelve shillings a week for the married men with families, and nine or ten shillings for the unmarried, which he seems to think an unfair distinction. "It is the custom," he says, "in Sussex, to make a broad distinction between the married and the single husbandmen; to pay the former higher wages than the latter; to get husbandry work done at a price relatively not to the value of the labour, but to the exigency of the labourer. And this practice may be said to prevail, more or less, throughout the agricultural districts of the kingdom. A labourer is paid wages in proportion to his imprudence, rather than with reference to his industry and skill."

"The effect," he says, "of the practice complained of must be either to drive the bachelor husbandmen from their native land, in sheer disgust at the gross injustice with which they have been treated, or to prompt them to early and imprudent marriage, in relief of that heavy discount upon their industry to which as bachelors, they have been most unwisely subjected. In the one case the farmers lose their best men; in the other, they make a premature provision for a pauper population."

The tolerably confident and arbitrary decisions of Mr. Acland are based on the gratuitous assumption that a married man cannot or does not labour so well as a bachelor, and yet the common practice is to reward or pay him more. Mankind are generally swayed by their interests, and when the great body approve of and practice a mode of securing their interest, it may be fairly assumed that they have as good a chance to be right as he who so roundly condemns them. But the common sense, as well as the common experience of mankind, may be appealed to in this way—that a married man having a greater interest at stake, having provision to make for more mouths than one, cannot on this account be supposed to labour less than he who has only to provide for one. The married, then, may reasonably be supposed to do rather more than less on that very account. He cannot so easily shift his quarters as the bachelor, and on that account, not an unimportant one, be surer at all times to be had for the service of his employer; whereas a more ambulatory labourer is not likely to be so generally useful, on that very account, that he can quit his location at any time, and without previous notice or warning. Again, the family of the married man becomes useful to him in the way that he is so to his employer, and helps, too, in youth and to manhood, as a labourer more likely to be had at all times, than a more isolated bachelor. And, again, unless the labourers married and had families, where and how is the succession to be kept up, and the ranks of the 20,000 to be supplied as they die off?

In short, it may be well questioned whether Mr. Acland's notions have any solid foundation in either fact or theory. My course hitherto has been confined to the single position of the parties in respect of interested motives, and the mere supply of animal wants; and here I would observe, that great addition may be made to the comforts of the labourer, in which the married man will

be no incumbrance to the farmer, but the reverse; I mean by the allotment system of, say, a quarter of an acre to each, *at the farmer's rent*.

Before, however, going into this matter, let me go on a step further from Mr. Acland's evidence. He says the greater portion of the married labourers of Sussex have garden-grounds attached to their cottages, an average of nine rods, or the eighteenth part of an acre, at the moderate rent of twenty-three pounds per acre! or about twenty times the farmer's rent! This is to aid him and his family. And yet at this exorbitant rent, tenants are found.

Many have no gardens to their cottages, and these pay for a quarter of an acre fifteen shillings, or *three times only* the rent of the farmer; and over the leaf we find that for potatoe ground they pay *four times* the rent, and clear the land for the farmer by the same operation.

My readers, I hope will go with me in this commentary, and bear in mind the appalling facts disclosed. All these I shall class as negative evidence of the benefits of the allotment system. For the positive, we have only to turn a very few pages back to the infinitely more pleasing, humane, and gratifying address of the Rev. W. B. Whitehead, Vicar of Chard, who says that "If the allotment amounted to a quarter of an acre and was well cultivated, the direct increase of income which it afforded him, the labourer, could not be calculated at less than two shillings and sixpence, independent of the great advantages of health which a constant variety of wholesome and nutritious food at all seasons of the year afford."

Turn we again to Mr. Acland, in the account given of the week's wages of twelve shillings, which leaves not a farthing for clothes, and gives less, by 2½d. per head, to the labourer's family than is provided for the pauper in the workhouse. Taking all this for granted, then the allotment system, as stated by Mr. Whitehead, would supply two shillings and sixpence a week more, thereby making up, in all probability, for the otherwise destitute and deplorable state of their family. This is positive evidence, and demonstrates as clearly on the one hand, as the negative on the other, the extreme value and utility of the system; for be it again and again repeated, *no one loses, and every labourer gains by it*.

Having opened the business thus far, let us now see what sacrifices, as it is supposed, are needed to put the 20,000 labourers in possession of a quarter of an acre each. Five thousand acres would suffice, and this deducted from 903,000, leaves still 898,000 for all other classes. Why, if it were deducted as an actual loss, and that taken solely from the uncultivated or waste acres, it would scarcely be felt by the aggregate proprietors. But if, as is manifested, not in many cases, but in every instance without a single exception, that the benefits are reciprocal, in that the rents are as well paid as the farmers, then does not all doubt vanish as a vapour or a cloud, that passes away almost as soon as seen? On this part of the subject, independently of all experience which is as above, it may be firmly stated that the proper security for all rents, of great or small farms, is in produce. The produce of the allotment tenant is generally double of that upon large farms, sometimes treble, and in some instances quadruple. Is there not then double, treble, and quadruple security, in the more abundant produce for the rent, *if that rent be as it ought to be*, the same in proportion as the larger farmers? Here, again, who loses? No one. Who gains? The labourer; and by his own exertions too, without other aid of any one.

Turn we now to another part of the same magazine, page 59, as to the mode of making manure for the allotment tenant. This he can do even without a pig, and effectually too, and on a principle that never fails. The more produce the more manure, or means for making it. Again, the more manure, the more produce, generally speaking; thus giving a double reward and encouragement to the industry of man. A very little, indeed, is needed to better the condition of every labourer in the kingdom. That little is no more than what every one is entitled to, for it is in that way only,—*there is no other*,—that the Divine command can be obeyed, which

being the first with promise, is of universal and never-ceasing obligation. "Be fruitful and multiply, and replenish the earth and subdue it."

Without at all examining into the relative population of Sussex and its cultivated or productive lands, I shall now advert solely to the 110,000 acres that are called waste. To bring this waste into the same state as the rest would need a greater proportion of labourers than for the acres already in cultivation. But even at this rate the 110,000 acres, at 40 acres for each labourer to cultivate for others, would give employment to upwards of 2,700 labourers, in addition to the 20,000 now engaged in agriculture. If so, and there seems to be no doubt of it, then the labourers may marry and have families, for a considerable time to come, with great advantage to the community, even on the statement given in Mr. Acland's summary. The waste acres must inevitably remain waste until there are more human beings to cultivate them; so that the premium, as Mr. Acland terms it, on marriage, is not so ill founded as he would make it appear. But my readers will, probably, be greatly surprised to be informed that on evidence given before the Emigration Committee, seven years ago, thirty-six individuals in Ireland extracted a subsistence from six acres of land, or six to an acre. In Sussex the population is three acres to a man, a difference of eighteen to one. Take only one-half of this increase, and we come to a capability in Sussex to maintain an increase to the population of 2,400,000 souls.

This seems astounding, yet it is not unfounded; but what becomes of Mr. Acland's theories and facts in the teeth of such evidence? Recollect this is so far hypothetical only as it is untried, and must remain untried for ages to come probably, but is no more problematical than the plainest demonstration of past experience in what has been, and therefore what may be done again when necessity requires it.

J. I. B.

FOREST TREES OF GUIANA.—The fitness of the timbers for naval architecture is unparalleled, and in some instances is said to surpass the teak. The greenheart, the mora, and souari or sewarri, of all other woods, are most unquestionably the best adapted for ship-building. Within the last ten or twelve years a considerable quantity of brown greenheart has been sent to Liverpool and Greenock; and I have been told that builders and others interested in shipping are now of opinion, after about ten years trial of the wood, that in strength and durability it is superior to any oak, and it actually commands a higher price. Had these woods been introduced, and extensively employed in the royal dock-yards fifteen or twenty years ago, it is the opinion of competent judges that we should not now hear much of dry-rot and Kyan's patent; and not to mention the rapid decay of vessels built of English and African oak, and the consequent frequent repairs, with what saving to Government would it not have been connected! If, therefore, the attention of the navy-board could be drawn to the important fact that British Guiana can furnish the finest and most durable wood in the world, in sufficient quantities to supply all the ship-building establishments in Great Britain, a double benefit would arise from it, namely, the saving to government and the increased demand for the natural production of the colony. The first experiment might be made to establish a dock-yard for the repair of such of her Majesty's cruisers on the West India station as draw not more than eighteen or nineteen feet water. The outlay of such an establishment would be trifling, if the importance of ultimate success be considered. The woods, which are qualified for ornamental purposes, vie in elegance, if polished, with any in the world. The want of labourers is the great cause that these treasures lie comparatively hidden, and have scarcely excited attention. The demand in the colony has been so great for native woods, that these who are at present employed in that trade are not able to meet it.—*Schomburg's Description of British Guiana.*

MACHINERY EXPORTED.

RETURN to an Order of the Honourable the House of Commons, dated 24th March, 1840;—for an ACCOUNT showing the several Countries to which Machinery has been exported, with the Official Value thereof, in each Year, from the 1st day of January, 1830, to the 1st day of January, 1840, inclusive.

Inspector-General's Office, Custom House, London, }
13th April, 1840.

WILLIAM IRVING,
Inspector-General of Imports and Exports.

CENSUS OF AGRICULTURE IN THE UNITED STATES.

We are happy to perceive that this important subject has been taken up in the proper quarter, and that we are at least to have such an enumeration of the agricultural products of this country, as will furnish some safe estimate of the quantity produced, and the districts in which they are grown. In reply to some suggestions made by us on this subject, Mr. Deberry, the chairman of the committee of agriculture, has kindly forwarded us a copy of the instructions for the use and direction of the marshals and their assistants, from which we find that the following series of inquiries are to be propounded to every farmer. Although there are some products it would be perhaps desirable to have introduced into this list in order to render it complete, yet it contains all the most essential items, and if carried out in the spirit in which it seems to have been conceived, it will be a collection of vast importance and value to the country. Had such a census of our agriculture

been taken at every ten years, the comparison of the tables at different times would be of the greatest interest, as determining the increase in the product of our fields, and the districts in which the greatest fluctuations have taken place.

We have one suggestion to make in regard to this matter, which we consider of very great importance. It is this. Let every printer of a newspaper in the country, and in all the cities that print journals for distribution in the country, give a place to the questions which we copy below, and which will be propounded to every farmer in the United States. As it is to be hoped that there are few or no farmers who do not receive some journal, agricultural or otherwise, such a course would be the means of bringing the subject to their notice, and enable them to prepare their answers with greater correctness than they might otherwise be able to do. If every farmer who receives a copy of these interrogatories, would at his leisure sit down, and write against each one the proper reply, not only would the labours of the marshals be greatly expedited, but, which is of more consequence, a greater degree of accuracy would

be secured. The marshals will commence in June next, and proceed through their districts as soon as consistent with accuracy. The interrogatories refer to the crops of 1839, and to the products of that year must the answers relate.

AGRICULTURE—INTERROGATIONS.

What is the number of your horses and mules?
 How many neat cattle have you?
 How many sheep?
 How many swine?
 What is the estimated value of your poultry of all kinds?
 How many bushels of wheat did you grow in 1839?
 How many bushels of barley?
 How many bushels of oats?
 How many bushels of rye?
 How many bushels of buckwheat?
 How many bushels of Indian corn?
 How many pounds of wool?
 How many pounds of hops?
 How many pounds of wax?
 How many bushels of potatoes?
 How many tons of hay?
 How many tons of hemp and flax?
 How many pounds of tobacco?
 How many pounds of rice?
 How many pounds of cotton have you gathered?
 How many pounds of silk cocoons?
 How many pounds of sugar?
 How many cords of wood have you sold?
 What is the value of the products of your dairy?
 What is the value of the products of your orchard?
 How many gallons of wine have you made?
 What is the value of your home-made or family goods?

As intimately connected with these, may be added those relating to horticulture—which are as follows:

What was the value of the produce of your market garden in 1830?

What is the value of the produce of your nursery and green house?

It is hoped that editors friendly to the cause of agriculture, or who have readers in the agricultural districts, will give a place to the above interrogations, and invite the attention of those interested, that they may be in readiness with their replies. Let the first effort for an agricultural census of the United States, be met in a manner that shall ensure the desirable accuracy of the measure.—*Albany Cultivator*.

ON DRAINING.

TO THE EDITOR OF THE NEWRY TELEGRAPH.

SIR,—I perceive in your Paper of Saturday last a letter from Mr. D. Gardner, of Kirklandholm, in which he says he would, in one or two instances, willingly refer to some particulars contained in a letter from Mr. Kinmonth, which appeared in your columns some time since the month of February last.

Both the writers are unknown to me, except by name, and I beg to state that I have only seen Mr. Gardner's last letter, and that one of Mr. Kinmonth's, to some statements in which Mr. Gardner says, in his last, he would willingly refer. If Mr. Gardner is not able to write more correctly on agricultural subjects than he is to quote from Hudibras, "*God help poor Gardner and his readers too*," Mr. G. says,—

"CONVINCE a man AGAINST his will,
 He's of the same opinion still."

This is pure, unmixed nonsense. No created power could convince a man against his will—not even the greatest tile-maker the world ever produced. Dr. Butler, the author of Hudibras, possessed too much knowledge of human nature ever to think of work-

ing such a miracle as convincing a man against his will. What he has written is perfectly possible, and at the same time good sense:—

"He that COMPLAINS AGAINST his will,
 Is of HIS OWN opinion still."

But, as Mr. Gardner says, "in whatever part of the world he has been (*'he has seen, and sure he ought to know'*) he has invariably found that 'ignorance was the parent of prejudice;'" so I, who have lived at home all my life, have always found that ignorance and error are twin-brothers. But now for the draining.

If I have understood Mr. Kinmonth aright, his plan is this:—At the bottoms, or on the sides of sloping ground, or hills, or on any other ground, rising with a certain or gradual ascent, he would run a cut from the bottom, or lowest part, right up through the middle of the wettest part, to the source of the spring, or softest portion, at the upper end of the field. This drain, or conductor, I shall liken to the trunk of a tall aspen tree, the root or butt end of which, suppose to represent the drain, at the bottom, or lowest part of the ground, about to be reclaimed; and the top part thereof, the upper or higher end of the same trunk. Now it will, I think, appear obvious to the simplest agriculturist, even of the "*houseless wilds of Connemara*," that, when springs, or soft boggy ground lie on either side of this conductor, a little collateral sewer, like a side branch of the aspen tree, running off somewhat like a leg of the letter Y, judiciously directed, at an upward angle of less than 90 degrees from the trunk, into the upper side of the wet and "seepy," will produce on that portion the desired amendment. And going along this conductor, on either side, in any part where wet oozes out, make a judicious side cut, till all the wettish ground be thoroughly dried. This is Mr. K.'s system, which Mr. G. tries to mystify, and pretends not exactly to understand. Mr. K. does not mean that his transverse, or as I have called them, collateral cuts might fail in laying the land dry to the extent they run on either side; but he means that in case of the field about to be drained being so great in extent, that these side drains could not, in many places, be extended sufficiently far to catch all the water, you must choose your ground for another trunk, another parallel conducting cut, and to it, in the proper parts, attach or run the branch drains. Mr. Gardner again endeavours to obscure the plain sense of Mr. Kinmonth's observation about using clay for a manure. How clay taken from a transverse could be better than from a parallel drain, is more, Mr. Gardner says, than he can tell, and Mr. Kinmonth has not disclosed the secret. This remark has no wit in it. In writing the opinion "that clay (no matter whence procured) is to a light soil what it requires, and acts as a manure," Mr. K. had his mind fixed upon the much larger proportion of it that would be left out of drains, three-fourths of which were filled with stone, than there should be remaining after closing drains, of which only about one-fourth should be filled by tiles placed at the very bottom.

And now permit me briefly to offer my opinion on the comparative merits of stone and tile for forming these little aqueducts. Wherever there happen to be rugged stony "*knoces*" and waste scraggy patches abounding with loose or easily quarried stone, every preference should be given to it.

"Those rugged patches which deform the field
 Reward your labour. Raise the stone they yield,
 And form your drains; thus toil, with double aim,
 Dry knolls and swamps together to reclaim."

In many places the soil is so filled with loose stones, a little under the surface, that turning it up, and collecting them out from the earth, would leave the ground of much more value, so much so as, in many instances, to remunerate you well for the labour, even if the stones were not required for sewers. Mr. Gardner waxes most indignant at Mr. Kinnmonth's jest about tile-kilns springing up in Scotland like mushrooms. What is it to us how many manufactories of this kind there may be in Ayrshire? Would Mr. Gardner be so good as to inform us how many might be sufficient for the county of Meath; and how he would burn tiles there? In large districts the principal fuel, of even substantial landholders, is stubble, raked from the wheat or oat field, and the withered stalks of potatoes, collected with the nicest care. I suppose, if, like the Israelites in their Egyptian bondage, the *Meatheans* were to "gather the stubble throughout all the land," it would not burn one million of tiles, exactly the one hundredth

part of what Mr. G. calculates would be sufficient for the 400,000 acres that are practicable and worth draining in Ayrshire, at 3000 tiles to the acre.

If Pharaoh, when building the pyramids of Egypt, had possessed such an overseer as Mr. Gardner, he would have been of more service to him than ten Josephs. But to conclude for the present; in serious earnest, I do not see the least use in Mr. G. showing to us *Puddies* how very much he knows about Ayrshire, its extent, draining, &c., &c., and what it may be made in 35, nay in 20 years. Let Mr. G. enquire of Mr. M'Grath, of Claret Rock, near Jonesborough, how he reclaimed a large tract of half hilly, half mountainous, cold, springy, stony land; and what good he supposes 150,000 tiles buried in the trenches he cut would have done for him? But I trespass too long. Pray pardon your very obedient servant,

S. B.

Hill-street, Newry, April 27.

AN ACCOUNT OF BRITISH WOOLLEN MANUFACTURES

EXPORTED FROM THE UNITED KINGDOM IN THE YEAR 1839;

SPECIFYING THE COUNTRIES TO WHICH THEY WERE SENT.

COUNTRIES TO WHICH EXPORTED.	Cloths of all Sorts.	Napped Coatings, Duffels, &c.	Kerseymeres.	Baizes of all Sorts.	Stuffs, Woollen or Worsted	Flannel.	Blankets and Blanketing.	Carpets and Carpetings.	Wool-lens mixed with Cotton.	Hosiery, viz., Stockings, Woollen or Worsted.	Sundries:—Consisting of Hosiery not otherwise described, Rugz, Cover-lids, Tapes, & Smallware	Declared value of British Woollen Manufactures, Exported from the United Kingdom.

ON FURROW DRAINING.

TO THE EDITOR OF THE FARMER'S MAGAZINE.

SIR,—Being a reader of your valuable Magazine, I observe in your number for April, page 244, an article written on FURROW DRAINING, by a "FURROW DRAINER," from whose opinion regarding some points I would beg to differ.

It is alleged by your correspondent that furrow draining is a first-rate improvement in modern agriculture, and I am sure to this allegation every intelligent agriculturist will be ready to give his unqualified assent. Furrow draining is undoubtedly, on all clay or humid land, with a retentive subsoil, the ground-work of every agricultural improvement, and has been the means of facilitating much noble agricultural enterprise and profitable experiment; in fact it completely forms a new era in the management of the farm.

A "Furrow Drainer" goes on to state the period when draining commenced in the district from which he writes, giving a description of the manner in which drains are cut, to be filled with turf, wood, and stones, with the estimated cost. In describing the mode of filling drains with broken stones, which appears to me a good plan, he says, "and a covering of turf, furze, or straw, is put on, to prevent the small mould from getting amongst the stones." A "Furrow Drainer" does not contemplate that in putting furze or straw in a drain, above stones or tiles, these substances very soon decompose, and become a vegetable mould, very friable, and consequently calculated to go down amongst the stones, or be washed through the interstices of the tile channel by the filtration of atmospheric moisture, and in the course of a very short period will form little banks or impediments in the drain, and of course retard the current of water, or altogether destroy its usefulness, especially when in a level situation where little fall or run can be obtained. I am aware that the practice laid down by a "Furrow Drainer," of covering stones or tiles in drains with furze, straw, or litter of any kind, preparatory to filling in the earth, is quite prevalent in almost every district where I have seen draining executed, but, because common, it is not the less liable to mistake, and it has been proven so, very satisfactorily to my own mind, from practical observation. Draining, both deep and furrow, is an operation which I have studied much, and paid particular attention to the practical results of every experiment which has been made in that department of agricultural improvement, within my knowledge, and confidently assert that I have universally found those drains stand longest entire, and make the least discharge, that have been covered with a thin tough sod or scraw, above the stones or tiles, laid the green side undermost. This I have known to endure longer, and answer the purpose better, than any other article I have seen used; besides, a thin turf or sod can generally be got at no extra expense, and with little trouble, because when the contractor or workman has the line of drain marked out with the spade on both sides, (supposing the operation of draining to be executed in a lea field, which is now commonly the case, at least in this district,) the workman has only to take his spade, and carefully pare off a thin sod or turf from the site of the drain, and lay it to the opposite side to which he intends throwing the earth, and it is quite at hand when he wants it, at the filling process.

A little farther on, in a "Furrow Drainer's"

communication, he states that "the greater part of the carse being hard bottomed, soles are not thought necessary, and therefore not much used." It appears to me that furrow drainers have fallen into error on this point of no inconsiderable amount. If, in commencing any operation from the mere impulse of having seen the good effects of an experiment in any neighbouring district, without taking into consideration the varied results which must necessarily be effected under a multiplicity of circumstances connected with that operation, we are sure to be misled; and it is too often the case, that furrow draining is performed just as we see our neighbours do it, or perhaps the system changed to suit the opinion or caprice of some one who is supposed to have a knowledge of the matter, without ever giving ourselves the trouble of reflecting on the subject at all. I by no means, however, apply these observations to a "Furrow Drainer," but merely state what I know to be a fact, and which inert state of indifference regarding a thorough knowledge of furrow draining I have laboured to quicken and overcome. Now, I strenuously contend that furrow drains, in every description of soil, whether on a soft subsoil, or on the most tenacious clay or impervious till, ought to have soles. Where drains are made in moss or bog land, or wherever the bottom is soft, so as not to carry the tiles, and having a great flow of water, soles are indispensably necessary, but I consider them also necessary on other descriptions of subsoil, for the following reasons:—

1st. Where the ground is level or nearly so, the water runs much better on a well laid sole than on the earthy bottom; and also where the drains have much fall, and a strong current, soles are particularly suitable to prevent pooling.

2nd. A sediment is not so likely to be formed in the channel of a drain with a well laid sole, as when the water runs along the bottom of a drain finished with the shovel, which unavoidably leaves many little interruptions.

And last, although not least,—during summer, drains on a retentive till or clay bottom, generally discharge no water. Now, it is evident that the bottom of the drain becomes hard, and a crust is formed upon the surface, which, when the oozing springs again begin to issue forth, is thrown off, becomes softened or disunited by the increasing supply of water which runs the scaly mass along the bottom until it meets with some obstruction, forms itself into little mounds, which accumulate, and ultimately stop the drain.

In an earthy or sandy subsoil the evil increases to a greater extent. The crust affected by the action of the air in the drain, when free from water, and the earth thrown up by worms, form a greater depth, and to a greater extent, than many people are aware of, or are apt to suppose, and being of a finely pulverized substance, is easily washed into little embankments in the drain, and to a certainty, in no very considerable space of time, will destroy the usefulness of furrow drains to a great extent if not altogether. Besides, moles are apt to raise earth in furrow drains that have no soles laid, and so choke them up; whereas, when soles are used, none of the evils above enumerated can possibly take place: so, we ought always to keep in our minds' eye that the beauty and value of every improvement, whether in agriculture or otherwise, is in having it complete, and work to our satisfaction.

A "Furrow Drainer," in continuation of his subject, gives a few valuable hints regarding the

propriety of having tail or main drains, well sunk, and regularly cleaned out, which are essential points to be attended to; and after adverting to the depth he finds it necessary to make tile-drains, in the Case of Gowrie, (which in my opinion ought to be varied according to the nature of the soil and locality to be drained,) he ventures an opinion altogether contrary to the principle of furrow draining, and assuredly contrary to the testimony of not a few individuals who have had occasion to drain tenacious clay land: he says "and I am of opinion that, although the clays were perfectly consolidated above them, (the till channels,) they would still prove efficacious."

This is contrary to the clearest practical results. Many unsuccessful experiments have been tried in draining clay land, or land having a retentive subsoil, by open channels a certain depth beneath the surface. For instance, hay or straw ropes have been made of a certain size, and laid in trenches cut to the depth of from twelve to eighteen inches, and the earth or clay again replaced in the trench, above the rope, which no doubt soon became consolidated as the surrounding ground, and of course proved a fruitless attempt in the system of thorough drainage. Drains have been cut, too, in heavy clay land, in the form of a wedge, with spades made for the purpose, and the stamp cut out laid carefully on the side of the drain; and the covering process was performed by having a pole or round piece of wood, of a manageable length, and three or four inches diameter, which was laid in the bottom of the drain, and the stump or wedge-like piece of clay first taken out of the drain, being dressed on the bottom, was laid to rest upon the pole, and neatly fitted into the drain; when so much of the drain was filled in this way, the pole was drawn out, and the work carried on progressively until the whole was completed. The surface, under this system of drainage, was not destroyed, and in a short time the sward above the drain was equal to, if not superior, to the other parts of the field. Heavy cattle, of course, were not allowed to pasture for a considerable time, on land so drained, until the clay wedges, or covering of the drains or sewers, became perfectly united with its neighbouring parts; but this plan, too, was a failure in the system of furrow draining, experience clearly proving that so soon as the clay substance above the channel of the drain became perfectly united, and impervious to water, the land was in no better state than before the operation was commenced. I have, likewise, known drains cut in heavy clay land, and in land with a light top, and close retentive subsoil, and carefully laid with tile, but, from the want of stones or gravel being laid above the tile, or friable mould mixed with the clay to prevent cohesion, the drains in a short time became perfectly unavailable in rendering the land completely dry. The effect of the drains at first was very remarkable, but so soon as the clay surface became thoroughly mixed, during the operation of green cropping, and the particles of clay uniting together, and hardening into a solid crust, the ground during wet weather contained the atmospheric moisture to the same extent as before draining, even immediately above the drain, and I am sure the experience of many a furrow drainer and practical agriculturist will go to prove the same disheartening and disappointing circumstance.

Trusting that these remarks may be useful, and that you can give them a place in your valuable journal. I am, Sir, your very obedient servant,
Culhorn, 20th May. J. C.

TO THE EDITOR OF THE MARK LANE EXPRESS.

Allow me through the medium of the Mark Lane Express to answer the enquiries of "A constant Reader," with regard to the means used to kill yellow weed, which I suppose to be what is called (in Surrey) yellow boy—though the term yellow weed is, like yellow boy, rather indefinite, as there are other weeds bearing yellow flowers. If it is yellow boy, and growing on stiff land, a good dressing of chalk is the first step; if on lighter or sandy land, a light coat or dressing of chalk, or what I think is rather better, a dressing of soap-ashes. The following quantum of chalk on heavy cold land per acre, say 8 or 10 waggon loads; on light sandy land 5 waggon loads will be ample, even less would do; there is a danger of over chalking on light land, it should only be applied as medicine; 4 waggon loads of soap ashes has been found to do well; as a further help I should deem it necessary to drill and hoe. I consider the hoe, well applied, a great friend to the farmer. The above remarks are supposing (if the land is wet and cold naturally) that the draining thereof has been FIRST OF ALL attended to, because I am convinced it would be of incalculable benefit; indeed, if my observations are correct, the best land in the kingdom has been neglected more than any other—and draining ought to be the first act of the farmer; the landlord (at least) finding the materials. I have often thought the landlord's future interest would be found in his causing (by contributing the MAIN OF THE EXPENCE) his land to be well drained. If the above is worth insertion I shall be glad to contribute again. CLODPOLLE.

P.S. If "the constant reader" should be ignorant of the real nature of the weed spoken of, and it should turn out to be what is variously termed, but generally known by being called "Kilck or Charlick", my observations and recommendations would not apply, except the draining clause, which will be found of use on all cold wet lands, and as chalk acts on such land as a pulveriser, consequently such weeds as charlick can be easier got out of the soil, though not DESTROYED by the effect of the chalk. Clodpole, though a practical farmer, has never attempted to scribble for the public before, and though he regularly takes and reads the Express, he is not aware whether or no he is incurring any expense by writing thus; a hint on that head would oblige Clodpole in next—if his story is worth attention at all.

THE SHEEP SPIDER FLY.—Sheep are seldom at any period, or in any condition, wholly free from this fly (*Melophagus*), but its attacks are always most vigorous on hogs, and such as are in an unhealthy state. The irritation caused by the insertion of the proboscis and strongly hooked claws into the skin is so great, that the animal tries to obtain relief by tearing the wool with its teeth whenever the affected part is within reach of the mouth. This propensity occasionally gives rise to a singular accident. When the neck is much bent in the effort to reach the place irritated, the teeth sometimes become fastened in the wool so firmly, that the animal cannot extricate them, and soon loses the power of its neck. If relief is not afforded, it necessarily perishes in a short time. In such a case shepherds say that the sheep dies by being bridled.—*Quarterly Journal of Agriculture.* The same periodical says one of the best remedies against this pest is the process of smearing with spirit of tar, tobacco liquor, corrosive sublimate, and other substances of a similar kind.

IMPORTANT SALE OF SHORT- HORNS, &c. &c.,

AT MR. PARKINSON'S, AT THE BADWORTH FARM,
NEAR RETFORD, NOTTINGHAMSHIRE, BY MR.
WETHERELL, ON FRIDAY MAY 20TH, 1840.

The sale, although advertised to take place at eleven o'clock, did not commence until after one, at which time a very large company had assembled. Amongst the rest we noticed H. B. Simpson, Esq., Fairfax Fearnley, Esq., T. W. Edge, Esq., Strelley; G. S. Foljambe, Esq., F. T. Foljambe, Esq., Wm. Ladds, Esq., Ellington; Henry John Yorke, Esq., Thrapstone; Charles Barnett, Esq., Beds.; G. P. Harrison, Esq., Darlington; W. Beaufort, Esq., Biggleswade; R. M. Jaques, Esq., Richmond; J. Bradley, Esq., Blyth; William Holdsworth, Esq., Wm. Marris, Esq., Winterton; Frederick Walker, Esq., Blyth; Wm. Cartwright, Esq., Tathwell; Samuel Wiley, Esq., Easingwold; Henry Machin, Esq., Gateford; J. Clover, Esq., Cambridge; Rev. W. Fenton, Mattersey; Rev. F. O. Morris, Ordsall; Rev. Charles Eyre, Carlton; Rev. T. Cator, Messrs. Rose, Cottam; Hodgkinson, Torworth; Sharpe, Scarthing Moor; Clarke, Bamby Moor; Allison, Bilby; Short, Martin; Parkinson, Leyfield; Parkinson, Muskham; Henry and John Beavor, Blyth; R. Hodgkinson, Sen. and Jun., Morton Grange; G. Shaw, J. Rogers, Ranby; Weightman, Torworth; Bentley, Rotherham; Gyles, West Retford; Hall, Wiseton; Bower, Moorgate House; Wilkinson, Lenton; Booth, Cotham; Crofts, Ranskill; Cattle, Burghley; Robinson, Bletsall; Thompson, Arnin; Smith, Raisin; Wilkinson, Lenton; Booth, Louth; Codd, Grimsby; Wiley, Bransby; Wharton, Hatfield; Sandy, Homeclave, &c. &c. &c. After the conditions of sale had been read over and agreed to, the sale proceeded as follows:—

LOT COWS AND HEIFERS.

- 1 *Catalani*, roan, 6 years old, 28 gs.—Mr. Clover, Newmarket.
- 2 *Clementina*, roan, 5 years old, 30 gs.—Mr. Clover.
- 3 *Minster*, roan, 8 years old, 23 gs.—Mr. Kirkham.
- 4 *Fume*, roan, 7 years old, 24 gs.—Mr. Morley, Booth Flery.
- 5 *Brilliant*, roan, 6 years old, 25 gs.—Mr. Carter, Howden.
- 6 *Red Cherry*, red, 4 years old, 24 gs.—Mr. Barnett, Stratton Park.
- 7 *Sandal*, red, 5 years old, 20 gs.—Mr. Barnett.
- 8 *Junio*, red and white, 8 years old, 31 gs.—Mr. Barnett.
- 9 *Blanch*, white, 9 years old, 22 gs.—Mr. Beaufort.
- 10 *Palmblom*, white, 9 years old, 24 gs.—Mr. Kirkham, Hagnaby.
- 11 *Miss Salt*, roan, 6 years old, 24 gs.—Mr. Clover.
- 12 *Abess*, roan, 8 years old, 41 gs.—Mr. Hood, Nettlesham.
- 13 *Landlady*, red, 7 years old, 32 gs.—Mr. Beaufort.
- 14 *Nidia*, white, 5 years old, 41 gs.—Mr. Barnett.
- 15 *Evelina*, red, 6 years old, 28 gs.—Mr. Morley.
- 16 *Funny*, roan, 3 years old, 27 gs.—Mr. Clarke.
- 17 *Bellina*, roan, 5 years old, 30 gs.—Mr. Long.
- 18 *Minna*, roan, 8 years old, 30 gs.—Mr. Trims.
- 19 *Durham*, roan, 5 years old, 45 gs.—Mr. Codd, Holton.
- 20 *Elta*, red, 4 years old, 36 gs.—Mr. Jaques.
- 21 *Crotchet*, red, 6 years old, 30 gs.—Mr. Ladds.
- 22 *Aravice*, roan, 8 years old, 33 gs.—Mr. Hood.
- 23 *Fashion*, red, 5 years old, 46 gs.—Mr. Jaques, Easby.
- 24 *Sunflower*, red and white, 5 years old, 31 gs.—Mr. Townsend.
- 25 *Zuima*, roan, 9 years old, 25 gs.—Mr. Morley.
- 26 *Miss Smith*, red, 7 years old, 34 gs.—Mr. Beaufort.
- 27 *Pink*, red and white, 5 years old, 22 gs.—Mr. Hammond.

Lot

- 28 *Ione*, roan, 6 years old, 27 gs.—Mr. Morley.
- 29 *Caradori*, roan, 3 years old, 25 gs.—Mr. Broomfield.
- 30 *Rosalind*, roan, 4 years old, 30 gs.—Mr. Barnett.
- 31 *Lily*, white, 3 years old, 28 gs.—Mr. Yorke.
- 32 *Innocence*, white, 3 years old, 31 gs.—Mr. Booth.
- 33 *Alba*, white, 6 years old, 23 gs.—Mr. Yorke.
- 34 *Madeline*, dark roan, 3 years old, 31 gs.—Mr. Booth.
- 35 *Coriana*, roan, 3 years old, 29 gs.—Mr. Barnett.
- 36 *Adelaide*, roan, 4 years old, 220 gs.—Mr. Ingham, Halifax.
- 37 *Quicksilver*, roan, 3 years old, 21 gs.—Mr. Maw.
- 38 *Fleur-de-lis*, 4 years old, white, 17 gs.—Mr. Beasley.
- 39 *Marcia*, roan, 5 years old, 33 gs.—Mr. Morley.
- 40 *Rarity*, white, 5 years old, 34 gs.—Mr. Morley.
- 41 *Capable*, red, 5 years old, 41 gs.—Mr. Beaufort.
- 42 *Stately*, red and white, 5 years old, 26 gs.—Mr. Barnett.
- 43 *Pensive*, dark roan, 4 years old, 30 gs.—Mr. Frost.
- 44 *Tertia*, roan, 5 years old, 25 gs.—Mr. Hood.
- 45 *Vesper*, roan, 3 years old, 27 gs.—Mr. Hammond.
- 46 *Morea*, roan, 4 years old, 30 gs.—Lord Galway.
- 47 *Pine Apple*, red and white, 4 years old, 21 gs.—Mr. Barnett.
- 48 *Laura*, red and white, 5 years old, 40 gs.—Mr. Barnett.
- 49 *Clara*, roan, 4 years old, 35 gs.—Mr. Topham.
- 50 *Flora*, red and white, 3 years old, 29 gs.—Mr. Clover.
- 51 *Victoria*, roan, 2½ years old, 60 gs.—Mr. Jaques.
- 52 *Bracelet*, roan, 2 years old, 27 gs.—Mr. Jaques.
- 53 *Buxom*, roan, 2 years old, 27 gs.—Mr. Taylor.
- 54 *Quintina*, red, 2 years old, 20 gs.—Mr. Clover.
- 55 *Cara*, roan, 2 years old, 22 gs.—Mr. Clover.
- 56 *Opera*, white, 2 years old, 18 gs.—Mr. Clover.
- 57 *Constantia*, red and white, 2 years old, 25 gs.—Mr. Clarke, Bamby Wood.
- 58 *Dolphin*, roan, 2 years old, 26 gs.—Mr. Clarke.
- 59 *Specimen*, roan, 2 years old, 27 gs.—Mr. Kirkham.
- 60 *Stella*, red and white, 2½ years old, 37 gs.—Mr. Morley.
- 61 *Advice*, roan, 2 years old, 30 gs.—Mr. King, Brinkley.
- 62 *Daphne*, roan, 2 years old, 31 gs.—John Booth.
- 63 *Bluebell*, roan, calved Jan. 31, 1838, 42 gs.—Mr. Ingham.
- 64 *Susan*, red and white, 1½ years old, 27 gs.—Mr. Thompson.
- 65 *Lumatic*, white, 1½ years old, 18 gs.—Mr. Clover.
- 66 *Siberia*, white, calved May 1, 1838, 25 gs.—Mr. Brooks.
- 67 *Drusilla*, roan, calved April 23, 1838, 40 gs.—Mr. King.
- 68 *Cora*, red and white, calved June, 1838, 35 gs.—Mr. Sandy, Holm Laec.
- 69 *Flavia*, roan, calved July 4, 1838, 54 gs.—Mr. Ingham.
- 70 *Lerna*, red, calved Aug. 21, 1838, 15 gs.—Mr. Bircham.
- 71 *Adeline*, white, calved July 31, 1838, 61 gs.—Sir Edward Mostyn.
- 72 *Lina*, roan, calved October 9, 1838, 30 gs.—Mr. Thompson.
- 73 *Caprice*, red, calved Oct. 12, 1838, 13 gs.—Mr. Maw.
- 74 *Miss Cartwright*, roan, calved October 22, 1839, 22 gs.—Mr. Clarke.
- 75 *Madam*, roan, calved March 10, 1839, 30 gs.—Mr. Codd.
- 76 *Semele*, roan, calved March 22, 1839, 26 gs.—Mr. Clarke.
- 77 *Hecate*, white, calved April 14, 1839, 26 gs.—Mr. Barnett.
- 78 *Fatima*, roan, calved Aug. 18, 1839, 30 gs.—Mr. Jaques.
- 79 *Neva*, white, calved July 17, 1839, 16 gs.—Mr. Broomfield.
- 80 *Zenobia*, white, calved Aug. 20, 1839, 10 gs.—Mr. Smith, West Raisin.

LOT

- 81 *Arrot Lass*, roan, calved Sept. 12, 1839, 22 gs.—Mr. Booth, Kelston.
 82 *Dead*.
 83 *Margaret*, white, calved Nov. 17, 1839, 13 gs.—Mr. Townsend.
 84 *Justina*, roan, calved Nov. 28, 1839, 18 gs.—Mr. Booth.
 85 *Lucia*, roan, calved Jan. 18, 1840, 16 gs.—Mr. Townsend.
 86 *Mentha*, white, calved Jan. 31, 1840, 13 gs.—Lord Galway.
 87 *Penelope*, red and white, calved Feb. 22, 1840, 12 gs.—Mr. Beasley.
 88 *Dead*.
 89 *Clariada*, nearly white, calved Feb. 29, 1840, 12 gs.—Mr. Townsend.
 90 *Dead*.
 91 *Ebricty*, roan, calved April 23, 1840, 16 gs.—Mr. Jaques.
 92 *Flirt*, white, calved April 9, 1840, 10 gs.—Mr. Clarke.
 93 *Sauce*, roan, calved April 13, 1840, 11 gs.—Mr. Clover.
 94 *Bustle*, red, calved April 14th, 1840, 2 gs.—Mr. Thorold.
 95 *Dead*.
 96 *Conceit*, roan, calved April 20, 1840, 16 gs.—Mr. Booth.
 97 *Dead*.
 98 *Lavender*, calved in 1834, 30 gs.—Mr. Bower.
 99 *Letitia*, calved in 1835, 29 gs.—Lord Galway.
 100 *Bertha*, calved in 1837, 27 gs.—Mr. Frost.

BULLS.

LOT

- 1 *Collard*, (own Brother to Clementi, sold at the Strelley Sale in Sept. 1839, for 200 guineas,) roan, calved Sept. 4, 1839, 290 gs.—Mr. Fox, of Foxhall, Ireland.
 2 *Duvertion*, white, calved May, 1838, 70 gs.—Mr. Ladds.
Grachus, roan, calved Sept. 1838, 52 gs.—G. W. Hutten, Esq., Gate Burton.
 4 *Bob Logic*, red and white, calved March 27, 1837, 25 gs.—Mr. Bower.
 5 No bid.
 6 *Brentwood*, roan, calved March 12, 1839, 35 gs.—Mr. Perceval.
 7 *Dead*.
 8 *Shirley*, red and white, calved Jan. 3, 1839, 25 gs.—Duke of Rutland.
 9 *Julius*, red and white, calved March 1839, 40 gs.—Mr. Clover.
 10 *Plymington*, roan, calved March 20, 1839, 21 gs.—Mr. Hickson.
 11 *Bez*, roan, calved April 14, 1839, 21 gs.—Mr. Holmes.
 12 *Stevens*, red and white, calved June 8, 1839, 25 gs.—G. S. Foljambe, Esq.
 13 *Hudibras*, roan, calved June 7, 1839, 17 gs.—Mr. Cromdy, Aberdeen.
 14 *Salamis*, roan, calved July 29, 1839, 13 gs.—Mr. Allison.
 15 *Pollington*, roan, calved, Sept. 10, 1839, 9 gs.—Mr. Sanderson.
 16 *Lemnos*, roan, calved Aug. 14, 1839, 33 gs.—Mr. Clover.
 17 *Bourbon*, white, calved Oct. 28, 1839, 26 gs.—Mr. Thompson.
 18 *Brigand*, roan, calved Dec. 12, 1839, 14 gs.—Mr. John Hood.
 19 *Fergus*, red and white, calved Feb. 19, 1840, 6 gs.—Mr. Outram.
 20 *Marshall Soult*, white, calved March 6, 1840, 8 gs.—Mr. Clover.
 21 *Quibbler*, red, calved April 3, 1840, no bid.
 22 *Quirk*, white, calved April 3, 1840, 7 gs.—Mr. Clover.
 23 *Bechebor*, white, calved April 24, 1840, 4 gs.—Mr. Clover.

Lot

- 24 Another calf, 6 gs.—Mr. Clover.
 25 Ditto.—Ditto.
 26 Ditto, 3 gs.—Mr. Bromley.
 27 Beast, 22 gs.—Mr. Dirk.
 28 Ditto, 23 gs.—Mr. Bower.
 29 Ditto, 11 gs.—Mr. Thoroby.

NORTH SUFFOLK AND SOUTH NORFOLK AGRICULTURAL ASSOCIATION.

The second Spring Show of this Association took place on Friday, May 22, at Harleston, when the attendance of agriculturists was considerable.

The stock was exhibited in a meadow belonging to Mr. Shipston, and the whole displayed considerable merit; for though the number of animals was small, in comparison with the show of last year, yet the appearance of the stock indicated that great attention has been paid by the breeders, not only to symmetry, but also to what is of greater importance, blood and constitution. Mr. Case, of Thorndon, Mr. Dykes, of Braiseworth, Mr. Taylor, of Starston, and Mr. Ebdon, of Fressingfield, shewed some good cart mares and foals; particularly the latter gentleman, whose stock attracted much notice, but which unfortunately arrived too late for competition. A cart gelding, also shewn by Mr. Taylor, was a clever animal. There was a splendid Suffolk bull, belonging to Lieut. Gen. Sir E. Kerrison, M.P., the President, which was greatly admired; but this animal having before won a prize, could not enter the lists of competitors at this exhibition. Mr. Case, and Mr. Dykes, shewed some Suffolk cows; and cows of other breeds were shewn respectively by Mr. Spelman, of Aldburgh, Mr. Theobald, of Starston, and Mr. Harvey of Harleston. The latter gentleman also shewed a dairy of eight Durham cows, and a bull, which were reckoned by competent judges to be very superior animals; but some of these had also successfully competed at former exhibitions. Mr. Dykes shewed a good Suffolk, and Mr. Harvey, a good Durham heifer, for the dairy. This description of stock was particularly good. As to sheep there was very little competition. Mr. Harvey, of Harleston, produced some good shearing Southdown ewes with lambs, and also some good Southdown ewe hoggets. Sir Edward Kerrison had some of the latter on the ground, which attracted much notice. Mr. C. Etheridge, of Starstone, shewed a capital Leicester ewe hogget, which was much admired for symmetry and texture of wool: Mr. Muskett, of Roydon, a very good fat Shearling Wether Sheep, and Mr. Harvey, two Southdown Shearling Rams, which were much noticed by graziers. Amongst the fat stock, of which there was only a small exhibition, Mr. C. Etheridge shewed a home-bred heifer, which like the stock generally belonging to that gentleman, possessed considerable merit. Mr. Harvey also, who is reputed to be a good breeder and an equally good judge of stock, exhibited a very fine half-bred Durham heifer, twenty-four months old, which was greatly admired, also as extra stock, a fat white Durham heifer, three years old; this was reckoned a good specimen of the breed. The quantity of swine was unusually small. We noticed only two fat hogs the property of Lord Henniker, and Sir E. Kerrison, and both were considered to be good animals.

The Judges were Mr. James Cooper, of Blythburgh; Mr. Louis Cottingham, of Reydon; and Mr. S. Robinson, of Henstead.

During the day there were present N. S. Holmes, Esq., the Rev. W. Lee, the Rev. J. P. Spencer, the Rev. R. Donison, the Rev. T. Sewell, T. C. Brettingham, Esq., W. Hazard, Esq., Dr. Crisp, Dr. Bunn, T. Utten, Esq., L. Taylor, Esq., B. Bond, Esq., the Rev. H. Harrison, C. Etheridge, Esq., F. W. Etheridge, Esq., J. Gedney, Esq., J. Clarke, Esq., James Ebdon,

Esq., Mr. H. Kersey, Mr. James Hill, Mr. E. Kersey, Mr. G. Gedney, Mr. R. B. Harvey, Mr. Flowerdew, Mr. Cooper, Mr. Cottingham, Mr. S. Robinson, Mr. Cuse, Mr. Peck, Mr. James Warde.

The Prizes were adjudged as follows:—

FOR STOCK.	£	s.	d.
To the owner of the best Suffolk cart mare, with foal at foot: Lombe Taylor, Esq., of Starston	3	0	0
To the owner of the best two-year-old cart filly, no competition	2	0	0
To the owner of the best two-year-old Suffolk cart gelding: Lombe Taylor, Esq., of Starston	2	0	0
To the owner of the best Suffolk bull: C. Etheridge, Esq., of Starston	3	0	0
To the owner of the best bull of any other breed: no competition	3	0	0
To the owner of the best Suffolk cow: Mr. P. Dykes, of Braiseworth	2	0	0
To the owner of best cow of any other breed: Mr. R. B. Harvey, of Harleston	2	0	0
To the owner of the best two-year-old heifer, for the dairy, of any pure-breed: Mr. R. B. Harvey, of Harleston	2	0	0
To the owner of the best five shearing Southdown ewes, with lambs by their side: Mr. R. B. Harvey, of Harleston	2	0	0
To the owner of the best five shearing ewes of any other pure-breed, with lambs by their side: no competition	2	0	0
To the owner of the best five Southdown ewe hoggets: Sir Edward Kerrison, Bart., M.P.	1	10	0
To the owner of the best five ewe hoggets of any other pure-breed: C. Etheridge, Esq., Starston	1	10	0

PRIZES FOR FAT STOCK.

To the owner of the best five fat shearing wether sheep: Mr. C. Muskeitt, of Roydon ..	1	10	0
To the owner of the best fat Suffolk or Norfolk home-bred steer or heifer: C. Etheridge, Esq., of Starston	3	0	0
To the owner of the best fat steer or heifer of any other breed: Mr. R. B. Harvey, of Harleston	3	0	0
To the owner of the best fat hog: Sir E. Kerrison, Bart., M.P.	1	0	0

SWEEPSTAKES:

A sweepstakes of ten shillings each, with two pounds added by Lord Bayning, for the best hackney mare or gelding, not less than four years old, not exceeding 15½ nor less than 14½ hands in height, was awarded to Mr. R. B. Harvey, of Harleston, beating Sir E. Kerrison, the Rev. J. Beddingfield, and Mr. G. Edwards.

A sweepstakes of ten shillings each, for the best Suffolk two-year-old cart gelding.—Not filled.

A sweepstakes of ten shillings each, for the best Suffolk two-year old cart filly.—Not filled.

A sweepstakes of ten shillings each, for the best shearing Southdown tup, was awarded to Mr. R. B. Harvey.

A sweepstakes of ten shillings each, for the best five shearing Southdown ewes, was awarded to Mr. R. B. Harvey.

A sweepstakes of ten shillings each, for the best Suffolk bull, was awarded to Sir E. Kerrison, beating C. Etheridge, Esq.

A sweepstakes of ten shillings each, for the best bull of any other pure-breed, was awarded to Mr. R. B. Harvey.

A sweepstakes of ten shillings each, for the best Suffolk cow.—Not filled.

A sweepstakes of ten shillings each, for the best cow of any other pure-breed, was awarded to Mr. R. B. Harvey.

A sweepstakes of ten shillings each, for the best Suffolk two-year-old heifer, was awarded to C. Etheridge, Esq.

A sweepstakes of ten shillings each, for the best

Suffolk yearling heifer, was awarded to C. Etheridge, Esq.

A sweepstakes of ten shillings each, for the best two-year-old heifer of any other pure-breed, was awarded to Mr. R. B. Harvey.

A sweepstakes of ten shillings each, for the best five pigs of the same litter, not less than three or more than six months old.—Not filled.

A sweepstakes of ten shillings each, for the best breeding sow, was awarded to Mr. P. Dykes, jun., of Eye.

SHEEP-SHEARERS.

Twelve Shearers on this occasion, all Norfolk men, entered the lists, and each having had assigned to him three half-bred Leicester sheep, belonging to Mr. Theobald, of Starston, the work began, the shearers laying the sheep on the ground instead of using a platform, as is the practice in some other counties, and which we believe is the practice in Suffolk. The men were not required to clip the sheep within a given period, but each was permitted to take his own reasonable time, that he might do the work well. The whole of the shearing was highly creditable to the several competitors, the wool being clipped close and even, with hardly a scratch upon the skins of the animals. The fleeces weighed from 6½ to 8½ lbs. each. The judges having examined the work, the prizes were awarded as follows:—

The first prize awarded to George Gooch, Watton	2	0	0
The second prize awarded to Charles Ray, Aldburgh	1	10	0
The third prize awarded to John Shanks, jun., Needham, near Harleston	1	0	0
The fourth prize awarded to W. Francis, Dickleburgh	0	10	0

THE DINNER.

About half-past four o'clock nearly 70 gentlemen partook of an excellent dinner, provided by Mr. Edwards, of the Magpie Inn. In the absence of Sir Edward Kerrison, in the House of Commons, the chair was taken by the Rev. W. Lee, who was supported on the right by the Rev. W. P. Spence, and on the left by C. Etheridge, Esq.: T. Utton, Esq., officiated as Vice-President. There were also present nearly the whole of the gentlemen whom we observed in the Shew Field. After the usual loyal toasts, the prizes were awarded: after which the company drank the health of the honourable and gallant President, amidst enthusiastic cheers. The other toasts were, "The Bishop and Clergy of the Diocese," "The Lord Lieutenants of the two counties," "Prosperity to the North and South Norfolk Agricultural Association," "Lord Bayning, with thanks to his liberality to the Association," "Lady Kerrison," "Lady Henniker," "Mrs. Holmes," "The Vice-Chairman," "The Venerable the Archdeacon Oldershaw, Rector of the Parish," "The Judges of the Stock," "The Treasurer and Secretaries," "The Successful Candidates," "The Royal English Agricultural Society of England," "The Unsuccessful Candidates," "The Members for the Two counties," "The Vice-Presidents."

HOW TO EXTIRPATE MOSS.—Your magazine of last month contained a query, "How to extirpate moss from the pleasure ground, without removing the turf?" I beg to recommend your querist to apply a top-dressing of wood-ashes in the proportion of 160 bushels to the acre, or thereabouts. I would not recommend it to be done in summer, as it will be too soon dissipated by the heat. Spring or autumn is the best time; if done in autumn, the ground, the following spring, should have a top-dressing of rotten dung, or other rich earth, mixed. If the ground is wet, draining will be highly necessary. It will thoroughly eradicate the moss, and bring the herbage of the most beautiful green colour and fine texture. As I have had ocular demonstration of what I write, I feel a pleasure in recommending it to the consideration of your querist—Jno. M'Envoy.—*Marnock's Flor. Mag.*

SPECIFICATION OF A PATENT FOR AN IMPROVED MOULD- BOARD FOR A PLOUGH;

GRANTED TO SAMUEL WITHEROW, OF GETTYSBURG, IN THE COUNTY OF ADAMS, IN THE STATE OF PENNSYLVANIA, AND DAVID PIERCE, OF THE CITY OF PHILADELPHIA, OCTOBER, 1839. PATENT ASSIGNED TO SAMUEL WITHEROW.

To all whom it concerns: Be it known that we, Samuel Witherow of Gettysburgh, in the county of Adams and State of Pennsylvania, and David Pierce of the city of Philadelphia, in the same State, have invented an improvement in the manner of forming the mould boards of ploughs, denominated by us the cycloidal mould board; and we do hereby declare that the following is a full and exact description thereof.

It is a principle resting on mathematical demonstration that a cycloidal arc, is that which offers the least resistance to a descending body; and it is hence deducible that an ascending body will pass up a cycloidal curve with less resistance than up any other.

The construction of our mould boards is dependent upon this principle. In forming them we employ the cycloidal curve in two ways, namely, to the formation of the concave of the mould board in the lines of ascent of the sward or furrow slice, in the act of ploughing. The second application of the cycloidal curve, is in the convex curve along the sole of the plough, constituting the part which enters and cuts the ground horizontally.

FIG. 1.

In the accompanying drawing, fig. 1, represents a mould board, A, being its point, and B, its heel; the line A, B, is that of the sole, constituting the lower edge which cuts the furrow slice horizontally. This curve in a plough which has been essayed, and has been found to answer well, was generated by a circle of eighteen inches in diameter.

In fig. 2, the curve C, D, E, may represent the cycloid generated by the circle F, the point D, which is that of the least curvature, corresponds with the point A, of the plough, fig. 1, the cycloidal line continuing to the hind part, or heel, at B. It will no doubt be advantageous to vary the curve according to the nature of the soil, a point to be determined by experience, but whatever variation may be found useful in this respect is still to be made in conformity with the principle upon which we proceed, namely, that of making it cycloidal.

The line I, H, along the upper part of the mould board, and in a plane parallel to that of the plane of the line A, B, we also make to fit the same cycloidal gauge.

In the plough which has been put in operation for the purpose of testing the principle, the lines of the ascent of the furrow slice, which govern the concavity of the mould board, were regulated by a cycloidal gauge made to a curve, generated by a circle of sixteen inches in diameter. Let C, D, G, fig. 2, represent such a gauge, and the lines a, a, fig. 1, to be assumed as those of the ascent of the furrow slice on the mould board; in forming said board we place the gauge in the direction of the line a, with the part D, which is that of least curvature at a, and thus proceed on until we arrive at the hinder part, B, H, withdrawing, or lowering the gauge at its lower end at each successive application, so that a smaller portion of the least curved portion towards D, and a larger portion of that towards C, shall touch the mould board; these successive depressions may be indicated by the division at b, upon the gauge. The degree in which the mould board shall curve, and hang over at H, for turning the furrow slice, may be varied according to the judgment of the maker, the curvature being governed by the diameter of the generating circle, and the degree in which the gauge is depressed at every successive application of it.

Having thus fully set forth the nature of our invention, and shown the manner in which we carry the same into operation, what we claim therein is the giving to our mould board the segment of a cycloid, convexly on its face in line leading from front to rear, and concavely in the lines of the ascent of the furrow slice, in the manner and for the purpose herein described.

SAMUEL WITHEROW.
DAVID PIERCE.

REMARKS BY THE PATENTEE.—A principal object in ploughing is to pulverize the soil, and the only way in which this can be effected by the plough, is by bending the furrow slice on a curved surface, so formed as that it shall also twist it somewhat in the manner of a screw. Such a surface will be formed by taking a strip of iron, and twisting it after the manner of a screw auger; and if there is given to this piece of iron a greater twist at one end than at the other, cycloidal curves may be thereby produced. Now as the curvature of the cycloidal mould board generally increases from the lowest to the highest point of ascent, it follows, necessarily, that the furrow slice in passing along it will be more and more bent as it ascends.

By forming the fore part of the mould by means of that part of the cycloidal gauge which has the least curvature, and the hinder portion by that part which has the greatest, the bending of the furrow will continue, and be increased, as it passes horizontally, as well as in its ascent.

By forming the lines of ascent cycloidal concavely, and horizontal lines cycloidal convexly, the twist in the mould board will gradually increase from the fore to the hinder part, as the curves contract, which will operate very advantageously in pulverizing the soil. The convex cycloidal form given to the horizontal lines will cause the furrow slice to leave the mould board in a direction well calculated to prevent it from falling off in segments. The advantages possessed by this mould board, as has been abundantly proved in practice, are, that it will run light, and that it will turn the furrow slice over in a connected sheet, well pulverized.

ON A NEW METHOD OF FEEDING SHEEP ON TURNIPS.

BY JAMES STEWART MENTEATH, ESQ., YOUNGER,
OF CLOSEBURN.

(From the Quarterly Journal of Agriculture.)

"No person ever deserved better of a country than he who first cultivated turnips in the field. No plant is better fitted for the climate of Britain,—no plant prospers better in the coldest part of it,—and no plant contributes more to fertility. In a word, there has not, for two centuries, been introduced into Britain a more valuable improvement."—*Lord Kames's Gentleman Farmer.*

Of all the domestic animals of our island, sheep are of the greatest importance to the farmer and the community. Sheep can be reared in situations where scarce any other animal can subsist. In their fleeces they supply a valuable article, which, by its manufacture in the woollen trade, gives employment and a living to thousands, and thus contributes, in no small degree, to the productive labour, the commercial prosperity, and the opulence of every country, in which these animals are bred on a large scale. Sheep husbandry, being so very valuable a branch of rural economy, well deserves the utmost attention of the farmer, who derives no small part of his profits from it. Though much has been done to improve the breed of sheep in Scotland, and to supply them with better food at all periods of the year, much yet remains to perfect the feeding of these animals when folded on turnips; and as every exertion is now making in our northern part of the island to render land more productive by drainage and subsoil ploughing, why should we be left behind other parts of the kingdom in making every proper effort to fatten our sheep in the shortest space of time, at the least possible waste of food, and in supplying greater quantities of butchers' meat, now so necessary at all times of the year for the sustenance of a population, whose numbers are yearly on the increase?

* "It may serve to afford some idea of the extraordinary increase and improvement of live stock in Scotland throughout the whole period (from 1723 up to the present time), and the extent to which the feeding process has been carried, to state, that Glasgow, in 1763, though that city had then a population of 30,000, the slaughter of cattle, for the supply of the public market, was wholly unknown. The number of sheep and oxen there required now does not materially differ in proportion to the greatly increased number of its inhabitants from that furnished to the city of London. In 1831, the population of London amounted to 1,472,000; and, at an average of three years, ending with that time, 156,000 head of cattle, and 1,238,000 head of sheep, were annually sold in Smithfield market (*M'Culloch's Statistical Accounts*, p. 586). In the other large towns of Scotland, there is reason to believe, a demand in a similar ratio exists. Such has been the extraordinary improvement in the condition and habits of the people. The whole of this supply of butchers' meat is now furnished to Scotland by her own agriculture; and, besides the large exportation of lean stock to the neighbouring kingdom, a very considerable number of fatted animals are continually being sent thither from the north, east, and south of Scotland,—an amount which has been lately much increased, from the

Great progress has been made in all branches of farming, but no department has undergone greater improvement than the feeding, rearing, and general treatment of sheep. During the late war, the rapid rise in the price of all kinds of meat, and the stimulus also given by numerous agricultural societies,—and, above all others, the Highland and Agricultural Society of Scotland, instituted to spread useful information and excite enquiry,—added to the example of many public-spirited farmers, gentlemen, and noblemen, are circumstances which have contributed, perhaps, to rouse the attention of every agriculturist to place the science of feeding farm stock on the best and most economical principles. How much soever Scotland may surpass the southern parts of the island in other branches of her husbandry, in that of feeding sheep, when folded on turnips, it must be admitted she has something to learn from the eastern counties of England.

The management of sheep, when fed on these roots, is well understood in Norfolk, Lincolnshire, and the Wolds of Yorkshire. The Scotch farmer, studious of his own interest, would do well to direct his attention to this subject. The treatment of sheep in the districts just named is not, perhaps, so generally understood as it deserves to be. We shall, therefore, offer a short description of it, hoping to see it ere long universally introduced into this country.

Since the introduction of turnip husbandry into Scotland, the cultivation of that valuable root has become universal. Abundance of food is thus supplied for the flocks during the winter season; greater numbers of these can be reared; and, by folding them on turnips, her poor, light, sandy, gravelly soils have been rendered fertile, and capable of yielding luxuriant grain crops. The introduction of steam navigation, also, a new era in Scottish rural economy, having brought the markets of the south within her reach, has encouraged many to cultivate more extensively the turnip crop. The demand also for fat meat being continually on the increase, it has become a profitable business to the farmer to feed as many sheep as he possibly can; and, instead of driving his flock southward in a lean state to market, the above facilities, and increased demand, have enabled him to bring them into good condition at home. Owing to all these things, a great revolution has been effected in the management of sheep. It ought, therefore, to be the aim, as it is the interest, of the Scottish proprietor to adopt in theory, and reduce to practice, whatever may enable him, in the readiest and least expensive way, to fatten his stock, and bring it into marketable condition. Towards this, he would be greatly assisted by following the method pursued by the English farmer of the eastern counties in his management of the flock.

It may be remarked, that the soil of the counties of England, where this new plan of feeding is now so generally practised, rests upon the chalk formation. As the soil in almost every case partakes of the ingredients that compose the rock upon which it lies, in the districts of which we speak, it is composed chiefly of calcareous matters,—flint mixed with vegetable mould of a sandy, loamy nature. In other parts of this chalky stratification, as in the Wolds of the East Riding

greater facilities afforded by steam navigation."—*Journal of English Agricultural Society*, vol. I., part I., p. 102.

of Yorkshire, we find more clay blended with the soil; and there is a subsoil in some places, of a reddish clay, verging in depth from a few inches to a foot or two, resting upon the chalk rock. This soil, made up of these constituent ingredients, naturally produces a good pasturage for sheep, though of a close, short herbage. Under a proper arable cultivation, it yields luxuriant crops of oats, barley, wheat, sainfoin, turnips, and mangels. Although this soil rarely possesses a depth of mould of more than five or six inches, it requires every twenty-four years to be top-dressed with chalk, which is raised from underneath out of deep pits, and then spread over the surface, at the expense of from 2*l.* to 3*l.* per acre. If this calcareous manuring be neglected, the grain crops become light and unproductive, the red clover degenerates into a worthless and dwindled plant, and the turnip failing to round and bulb, breaks out into the disease commonly known among the agriculturists by the name of "*fingers and toes*." On the other hand, this top-dressing of chalk, at the interval specified above, restores the productive virtues of the soil, and crops of all kinds are again yielded in abundance. This application of chalk to the soil affords a curious and striking instance of the necessity of dressing all soils whatever with calcareous manure. It is, for example, pursued with immense advantage in Craven, Yorkshire, which is one of the richest and oldest grazing districts in the north of England. This extensive tract is incumbent on the carboniferous, or mountain limestone; and its soil must, as we may well suppose, be highly impregnated with calcareous substances. Still, however, it is found essential to make it produce the grasses in abundance, and of good quality, that it be top-dressed every ten or twelve years, and that very largely, with newly burned lime. It is not unusual, we are informed, to lay on an acre as much as 300 imperial bushels of this mineral manure. Invigorated by this dressing, the grasses and clovers spring up in the richest luxuriance. And if this practice be indispensable in these highly calcareous counties, how much more necessary for all other soils, which, not resting upon a substratum of chalk or of limestone, have little in their composition of those ingredients essential to the promotion of their fertility, and the full development of their strength.* In an interesting article "*On increas-*

ing the depth of soil," by Mr. Johnson, which appeared in this journal lately, the farmer will learn that a large quantity of lime and other earthy substances, are yearly withdrawn from his soil by all the vegetable plants he cultivates on his farm. And he will also be made aware how necessary it is, from time to time, in order to preserve the fertility of his fields, to apply, in addition to animal and vegetable manures, those of lime and other earthy minerals, which the grain, grass, and root crops are every year abstracting from his land. The renovation of the soil by lime, in the method just mentioned, was not, it would appear, unknown to the Romans, while masters of our island. In the Wolds of Lincolnshire, and elsewhere in the chalk range of stratification, chalk pits of very great antiquity occur, and where is the improbability that that intelligent

that of the eastern counties being 26½; and of the western, 37. At Edinburgh it is 23½, whilst at Glasgow it is 29.65 inches. In the eastern counties the harvests are reaped seven days sooner than in the western, and, consequently, at less expense. Surely the western farmer should consider these facts. His fields ought to be subjected to a more thorough drainage, a greater number of them laid down in permanent pasturage, and new and then (the oftener the better) top-dressed with unstinted composts of lime, animal, and vegetable manures, that all the virtues of the soil may be brought out, and abundant vegetation produced. From the high value of dairy produce, and the increasing demand for fat meat, we are sure that a well-managed grazing system of husbandry in the western districts of Scotland, would return a higher profit than that of tillage. In the treatment of grass land, it will be found very useful to pass over it every spring in the month of April, either a heavy thorn bush, or a light barrow, once or twice. Afterwards to follow this scratching with a plentiful sowing of grass seeds, mixing with them some pounds of clover, red and white, and then give it a good rolling. The seeds collected in the hay-loft will go a great way to supply a sufficient quantity for every acre of the field. When the field is a meadow, either under irrigation or not, and mowed for hay, two or three pounds of Catstail-grass or Timothy, the *Fleum pratense*, should always be sown on each acre. No hay is superior to the Timothy in luxuriance and excellence, and in acceptability to the palate of all graminivorous animals. Nature seems to point out to man the necessity of replenishing every year his grass fields with fresh seeds. When she is left alone, she plentifully prepares a succession of plants, by shedding abundantly every where seeds to replace those plants that have disappeared. Since the introduction of sheep and cattle, the stalks of various grasses being eaten, few are left to bear and ripen their seed. Mowing the field, also, interferes with the ripening and shedding of seeds necessary for the production of fresh plants. Thus from constant grazing and repeated mowing of the same grass field, it is found in the generality of soils yearly to become thinner of plants, and yield lighter crops of hay than it had carried in former years. Were, however, this simple management, just recommended, carried into practice, our pasture and hay fields would be annually replenished with an abundance of fresh, healthy vegetation, and consequently would carry a greater number of stock, and yield to the scythe a heavier cut of hay. Whenever top-dressing is laid upon such fields, the same management ought to be applied to it.

* In the management of pasture on grass land there is much room for improvement in Scotland. It cannot be denied that we are too partial to the use of the plough, as if tillage were in every case the most profitable husbandry. Were a much larger extent of country kept permanently in pasture, were the enclosures effectively sheltered by belts of plantations and well drained, and the fields occasionally top-dressed with calcareous composts, we are confident that both landlord and tenant would find their respective interests promoted, their profits greater and also more secure. The climate of all the western parts of Scotland being humid, and saturated with moisture by frequent and copious rains, grazing and dairy husbandry would be found in very many districts to be more advantageous than tillage. It is believed, and, we might add, almost ascertained by actual experiment, that one-third more rain falls on the western side of Scotland than on the eastern. In proof of this we refer to the returns of the rain-gauge. The average quantity of rain that falls in Scotland within the year is calculated at 31 inches;

people, acquainted with the use of calcareous manure in agriculture, had availed themselves of the chalk to dress their tillage land in the districts where it is found? We may farther observe, that, in these light chalky soils, *bone manure* is most extensively used to raise turnips, and great improvement by this application has been effected in these soils.

It is generally allowed, that, in the feeding of all sorts of animals, the sooner their appetite can be satisfied, the sooner will they lie down to rest. In these circumstances, an animal very soon takes on flesh, and becomes fat. The reverse happens, when a long time is taken up in satisfying the cravings of their hunger. It is on this principle that the practice has been introduced into the eastern counties of England, of presenting to sheep, when they are folded on turnips, these roots cut up into long, thin, narrow slices. When this is not adopted, but the animals merely turned in upon turnips, and left to do the whole work themselves, many hours, often a whole day, are consumed, before they have satisfied the demands of nature; and thus little time remains for rest, rumination, and sleep.

The formation of the mouth of the sheep, indeed, points out to the owner of the flock the necessity of assisting the animal by artificial means to eat the turnip. Sheep, like all other ruminating animals, have eight cutting or incisor teeth in the front part of the lower jaw, but none in the upper. They have six grinding or molar teeth, on either side, both in the upper and lower jaw, making altogether the number of twenty-four. Between their front teeth and the grinders, there is a vacant space of nearly an inch and a half. It is very rare to find the newly-dropped lamb with any front teeth; but when a month old, it has a complete set of front cutting teeth. The two front teeth of the under jaw drop out at the end of the year; six months after, the two next to these are shed; and at the end of five years the teeth are all renewed. (See Blacklock's *Treatise on Sheep*, p. 10.) At or soon after Christmas, the two front teeth of the hogg sheep, when put on turnips, either fall out or become so loose as to prevent them from tearing up and masticating the root with ease. And it is believed by some, from the circumstance of these young sheep losing their broad or middle front teeth while put on turnips, that they never have them properly replaced with new ones. As winter sets in, the frost rendering the vegetable harder and more tough, particularly of such sorts as the Swede, whose firmness of texture makes them more durable, it must be evident that the young sheep, having their teeth in this defective condition, will find it no easy matter to obtain their daily meal. Hence the poor animals, in many instances, with bleeding mouths, pass the greatest part of the day painfully struggling to fill themselves; and are deprived of that wanted period for rest and rumination, so indispensable to bring them rapidly forward into condition. The owner is surprised and mortified, after having had his flock confined so many weeks, even months, to find that his hogg sheep, though abundance of good keep was supplied, are very far from being fat and fit for the butcher, and that they require, after the turnip season, to be pastured for some months on grass, to make them fit for the market.

The same remark applies with no less force to the more aged sheep, particularly the old ewes,

whose teeth, from various causes, are often in a decayed and defective state. It is a well-known fact, that, when folded on turnips which are frozen, there is not only greater danger of their falling off, but even of not being able sufficiently to satisfy their hunger. This evil can easily be prevented by cutting down the turnips into small, narrow pieces, and presenting them in wooden troughs. The sheep can take them easily into their mouth, and manage them with their grinding teeth, which are not liable to so many accidents and diseases as the front or incisor teeth, and which do not undergo so many changes.

Besides the defective state of the teeth of young and old sheep disabling them to eat freely the turnips on the ground, Blacklock, in his able treatise on sheep (p. 145), states that there are many varieties of sheep incapable of feeding on turnips, owing to the form of the face, the uppermost jaw projecting considerably past the lower, hindering the chisel-shaped front teeth from being brought to bear upon the root. The sheep, having the jaw in this state, in Scotland, are called *grun-mouthed* sheep, resembling in their profile that of the pig.

Few intelligent flock-masters can be ignorant of the waste and injury their turnips suffer from allowing their sheep, when upon them, to eat them indiscriminately on the ground. Whenever sheep are let into a turnip fold, they run over the whole, and then eat such of the tops as they have not trampled down. Many of the turnips, before they are tasted by the sheep, are liable to have their bark or rind broken by their sharp hoofs, which injury exposes the root to the wet and frost, and thereby occasions unnecessary loss. Others of the turnips are wasted by the sheep partially scooping out only a little morsel, and then leaving them to be trampled upon with great waste. Besides, when the turnips, being traversed over and trodden upon, are bespattered and befouled with urine and dung, and other filth, they must be unsavoury and disagreeable to the taste of the animal. Much complaint, in the last November Agricultural Report for East Lothian for 1839, is made of the sheep that were feeding on turnips confined by hurdles, having been injured by the rainy season, making these roots so foul and dirty. Such destruction of food in our northern climate is a serious loss to the owner. Our severe, backward, and cold spring, so trying to the flock, ought to persuade the breeder to use his utmost endeavours to preserve, by every means in his power, his turnips; and husband them by every precaution he can think of, to enable him to carry his sheep through this season of the year, when they are most pinched for sustenance, and when the ewe and lamb require succulent and nutritious diet. The farmer of those eastern counties of England already named, alive to the loss he suffers by folding his sheep in the usual way, has for some time abandoned it, and adopted another much more economical, and one by which he can bring in a shorter time his animals to market. The successful feeding of sheep, of course, greatly depends upon the quality of food presented to them; and upon the resources which the farmer possesses for supplying it during the severest seasons of the year. It cannot be effected without exact regularity in portioning it out, and strict economy in the management of the different articles on which they are to be supported.

Having thus, in a general way, stated that much remains to be done in Scotland toward the im-

provement of the management of sheep, and advanced a few reasons why this department of husbandry ought to engross a larger portion of the farmer's attention, we now proceed to a short description of the method pursued by the sheep-farmers of the eastern counties of England.

In the first place, a turnip-cutting machine, provided. In the construction of these there is great variety. We have inserted a drawing of one of the most approved form, from which the nature of the turnip-cutting machine will be understood.*

Some idea may be formed of the extent and estimation in which cutting turnips for sheep is held in some parts of England, when we state that Mr. Crosskill, an ingenious maker of agricultural

implements at Beverley, informed us that he had, within these last three years, supplied 400 turnip-cutting machines to the farmers in that part of Yorkshire, each machine costing 5*l*.⁶ To work

* For the information of those of our readers who have not seen this form of turnip-cutting machine, it may be proper to give a short description of it here. A is the hopper into which the turnips intended to be sliced are put, the roots and tops of the turnips having been previously taken off. The inclination given to the bottom of the hopper keeps the turnips always close to the cutters. B is a circular disc of cast-iron, revolving on an axle and driven by a handle. It acts the double purpose of forming a plate, upon which the cutting knives are fixed, and of being a fly-wheel to maintain a steady motion. The knives are of two forms, one a long straight knife for cutting the turnips into broad slices, the others are short ones fastened into the disc at right angles to the long knife, and whose province it is to cut the broad slices into narrow strips. In the ordinary form of the disc, which is cast in the same plane, it is frequently observed that the cut turnips do not freely leave the knives. To obviate this inconvenience, the portion of the disc immediately posterior to the knives is somewhat bevelled or twisted, to afford room to the strips to fall down. They thus freely fall down upon the inclined board C, slip forward upon it, and drop into the troughs on the ground. We believe it was Mr. Slight who first introduced the bevelled form of the disc. The small knives can be removed, and then the machine is converted into a slicer of turnips for cattle. The two wheels give a steadiness to the machine when in use much superior to only one wheel. It may be worth mentioning that we have seen a model of a turnip-cutter very similar to this one, which was made by a wright in the parish of Merton, in Berwickshire, fully thirty years ago,—so slow is the

progress of the improvements in agriculture.—
EDITOR.

* “The economy effected by this simple machine, which costs but 6*l*. or 7*l*., has been stated to us by an authority which would at once be admitted as very high, to be no less than one-third of the whole produce. If it be taken, however, only at a fourth or fifth, why, it may be asked, has not every farm in the country been long since furnished with this cheap apparatus? If a contrivance were discovered in Manchester which should save one-fifth of the cotton consumed in a manufacture (were such a saving possible), not a year could pass before most of the old machinery would be replaced by the new, and such changes are constantly taking place there, at the expense of many thousand pounds; but the turnip is the raw material of the farmer's stock, and the farmer is of the same enterprising race with the manufacturer; why, then, but on account of the separated and secluded scene of his industry, is the spread of agricultural inventions so slow, the extension of those which concern manufacturers so rapid; and what, but a central connection of the cultivators of the soil, can diminish and remove the obstruction?”—(Vol. i., part 1., p. 16, *Journal of English Agricultural Society*.)

We are much indebted to Mr. James Ransome, an able and intelligent maker of Agricultural Implements at Ipswich, for much information, most kindly communicated to us, respecting the management of sheep when fed with cut turnips, as well as for informing us of the best sorts of machinery for cutting turnips. We have similar thanks to offer to Mr. Crosskill of Beverley.

this machine, a man and a stout lad are hired. The two are able every day to cut turnips that will suffice to feed about 300 sheep. It is the general practice to commence using these machines as early as Michaelmas; and on no account whatever to suffer the Swede turnip to be given in any other manner. Wooden troughs are also provided. Each of these is ten feet long and eight inches wide at bottom, and seven in depth. They are placed upon feet or blocks of wood five or six inches high, to raise them from off the ground. The greater number of these are employed to contain the sliced turnips. But as cut hay and straw, salt, and pounded oilcake are daily allowed, some of the troughs are required for these articles. The troughs that hold the salt, oilcake, and cut hay, ought to have a cover over them to protect them from the rain and snow. Very great attention must be paid by the shepherd daily to shift, at least four or five times, the troughs from the place on which they have been standing, to other places within the field. By this attention every part of the ground will be equally well trodden upon and manured by the flock.

In the eastern counties of England the white globe turnip is not so much approved of, and less of it is grown than formerly. The more hardy and nutritive varieties are preferred, as the Swede and yellow bullock turnips differ in the quantity of nutritive matters they afford, which is in proportion to the size of the roots, or according as their texture is solid or spongy; the largest roots containing proportionally the least quantity of nutrition; the middle sized the greatest. At one of the Farmers' Club meetings at Ashbocking, in November last (1839), a Norfolk white turnip was exhibited which measured three feet and one inch in circumference. When cut open, there was only one inch and a half of firm substance within the rind, the rest being unsubstantial as a sponge, thus shewing that size is not the only excellence to be sought in the growth of these plants. The Swede or *Ruta baga* is superior to all other varieties. It is seldom injured by the frost, a matter of the greatest consideration in our climate, where the severity of the winter has, during these some years past, been most destructive of the white globe turnip. Although the Swede may be less productive in some soils in the average weight of crop than the globe white turnip, it contains more nutritive matter, being as three to two, and so ought to be more extensively cultivated in Scotland.* There is scarce any

light, sandy, gravelly soil, where, under proper management, it might not be raised with advantage. An extra quantity of farm-yard manure added to bones, with a few cwt. per acre of pounded rape cake, the poor soils might be made to yield fair crops of this valuable root. On the light soils of Norfolk, it is now pretty generally the practice to plough down the oat stubble as soon as the crop is carried off the ground, and sow rye. In the spring, the sheep, particularly the ewe and lamb, are folded on the rye, as upon turnips. As soon as the sheep have gone all over the field, it is ploughed up, and prepared for sowing those roots. By this excellent management the poor soils, being thus heavily enriched with manure, are made to carry heavy crops of turnips. Were the Scotch farmer to follow in this respect the example of the Norfolk husbandman with his light soils, he would insure abundance of succulent food for his ewes and lambs, at a time he is under such difficulty often to provide it, and he would also, by the rich manuring of his land, look with greater certainty for more abundant root and grain crops. At Holkham, in Norfolk, the Earl of Leicester, the father of English agriculture, who had last year 500 acres of turnip and mangel-wurzel on his own farm, raises, in considerable quantities, the green-top yellow turnip. He procures the seed from Mr. Leslie, seedsman, Old Meldrum, Aberdeenshire. This variety Lord Leicester sows as late as the first week of July. As this sort of turnip strikes its root deep into ground, it is preserved from frost, and by keeping sound to a late period of the spring, it is found a valuable means of support for the ewe and lamb. Where wheat is grown, rape is much substituted for the white-globe turnip, which, being early eaten down by the sheep in the autumn, the land is ploughed, and grain is immediately sown.

To return to the operations in the turnip field: The white globe turnips, as being the most perishable, are first eaten. They are pulled up, the tops and leaves removed, and are laid into heaps of from thirty to forty bushels each. These heaps are so distributed over the field, as to answer the convenience of the shepherd, who, in shifting his folds from place to place, always finds a heap or so at the spot ready to be cut by the machine for

in the autumn weighed nearly 38 tons per acre, and, when cleared of tops and roots, upwards of 34 tons per acre; whilst, on the other part, prepared in the usual manner, it realized in gross only 28 tons, and, when cleared of roots and tops, 25 tons 14 cwt. Mr. Scougall observes—"the result will speak for itself." If the increase here stated be in reality the result of this mode of preparing the land, it will prove to be one of the greatest improvements made of late years in cultivation. The land is admitted to be fertile, but it is a stiff soil, and consequently more difficult to get into a suitable condition to produce a turnip-crop than the ordinary turnip-soils. Here, then, is a method, whereby the produce of soils, until lately considered to be almost incapable of producing a turnip-crop, may be made to produce one-third more weight in food, consequently supporting animals one-third more in number, and ultimately raising a proportionably increased quantity of corn."—*Q. J. Agric.* No. 48, p. 650.

This autumnal management of stiff, heavy, clay land, intended to be in turnips the succeeding summer, is well adapted to Ayrshire, and all the tracts of Scotland which rest upon the coal formation.

* "It was stated, not long since, at a meeting of the English Agricultural Society, in their rooms in Cavendish-square, in London, by Mr. Maxton, that he had grown forty tons per acre of Swedish turnips. He mainly ascribed the increased produce to preparing his land for the turnip crop immediately after harvest, and even sometimes before the crop was removed from the fields. The advantage resulting from this mode of preparation is remarkably confirmed by an experiment upon the home-farm of Sir George Grant Suttie, Bart., at Balgone, in East Lothain, explained by Mr. Scougall. He says—"the experiments consisted simply in having a part of the field, intended for turnips, prepared in November, 1838, and the whole operation completed in the same manner as if the seed had then been put into the ground." The remainder of the field was prepared at the usual time. Upon weighing a drill of equal length in both parts of the field, it was found that the gross weight in that part which had been prepared

his "woolly people." As, in the early part of the season, there is little apprehension of injury from frost, it is thought a sufficient precaution to cover these heaps with their own leaves. But, at a later period, before the frost sets in with severity, the heaps, which are then collected, are secured by covering them with straw and earth. This practice is known in most of the eastern parts of England by the term of "clamping." Before the fold is entered by the sheep, every turnip is pulled up and removed. The wooden troughs, in number sufficient to supply every sheep, are placed at suitable distances, within the sheep-fold, which is fenced in with nets, or bays, or hurdles. The man and boy, having already cut the turnips, these small slices are thrown into the troughs, and during the day, at different and stated intervals, they are replenished. At the same time, great care is taken to disturb, as little as possible, the sheep reposing and chewing their cud. It is of the greatest consequence in feeding every sort of animal, that set and stated times of the day be observed for giving them their food. When sheep have eaten enough, they will lie down and ruminate. On no account whatever ought they at such moments to be broken in upon and disturbed. Their improvement in condition will rapidly go on if they are left to carry on the process of digestion without any molestation.

In the troughs, as we have before stated, cut hay and straw, salt and pounded oil-cake, are placed; occasionally, as a change of diet, bruised oats or barley are given. Of the oil-cake, at the beginning of the season, half a pound in the day is considered ample allowance for each sheep; but this quantity is gradually increased to one pound. After the sheep have remained the number of days that is thought sufficient to manure and tread the soil, the fold is then shifted to another place, the turnips having been previously all taken up, and piled in heaps outside, ready to be cut by the machines.

With this brief description of the new method of feeding sheep folded on turnips, by the farmers of the county of Norfolk, Lincolnshire, and the Wolds of Yorkshire, let us now state the reasons they advance why this improvement in sheep husbandry should be adopted.

1. The first reason has already been delivered in a foregoing part of this paper, and has reference to the teeth of sheep; but as it is a matter of importance to the farmer, it may not be superfluous to repeat it. The pulling and tearing at the turnip loosens the two front cutting teeth of the hogs and old sheep to such an extent, that they are apt to fall out, and, in many cases, actually do so. In this deficient state of the mouth, it is impossible that the younger animals can eat a hard Swede turnip, and in such a quantity as quickly to fatten and be ready for the market. Indeed, if the turnips be not cut, many of the flock can scarcely exist, and, while in the midst of plenty, may be actually starving. The teeth of the more aged sheep, again, from a variety of accidents and diseases to which they are liable, and from having been also much worn down by the hardness of many plants on which they have subsisted, are often, before they are put on the turnips, in a very imperfect condition, which necessarily prevents them from rapidly taking on fat, when folded on turnips, according to the old way. The malformation, also, in the structure of the upper jaw of some varieties of sheep, known in Scotland by the name of *grim-mouthed*, is another reason to adopt the plan of feeding sheep, when

folded on turnips, with these roots cut into thin, narrow slices.

2. That the hogs and the older sheep, when placed on turnips, will feed much quicker and be kept in a more healthy condition, when these roots are cut with machines into small, narrow slices, which they can easily take into their mouths, and which are placed before them in long wooden troughs within the folds; that they will sooner fill themselves, lie down, and ruminate. It is certain that when less time is taken up in eating, the more speedily will the animal become fat; the quicker that flesh can be laid on, the greater economy will there be of food. By treating the young sheep or hogs in this way, at about a year old most of them may be sent from the turnip field to market fit for the butcher. This is a very great benefit to the farmer, not only enabling him to increase the number of his sheep, but also better to prepare his flocks for growing his grain crops.

3. That sheep, penned in a fold on turnips like all animals under confinement, require a variety of food in order to make them fat. The habits of the sheep, both in its wild and domestic state, require its food to be very varied. Linnæus observed that while cattle ate 276 species of plants offered to them, and refused 218; that sheep took 387 species, and rejected only 141. Magendie, a celebrated French physiologist, has shown by experiment that it is impossible an animal in a healthy state can exist longer than six weeks on one article of diet; death often takes place even before the end of that period.* Hence the necessity of supplying the sheep, when on turnips, with a variety of articles of food. On this principle, in the part of England before named, each sheep receives in the day half a pound of bruised oil-cake, and this quantity is gradually to be augmented to one pound, or even more. As much salt also is given them as they will lick, it being a useful seasoning to their food, and indispensable to the health of all graminivorous animals. Steamed potatoes might also be supplied to the feeding flock. And we are confident that, with a proportion of such steamed food daily supplied them, their fattening would be hastened. It has been found very advantageous, while the ewes are nursing their lambs, to feed them with their salted maltcombs, giving about one sack to every hundred of them.† Cut hay is mixed with the scalded maltcombs. In those seasons, when turnips are a deficient crop, this diet is found a good substitute for the roots. These maltcombs, thus prepared with other artificial food, brings on very fast those sheep that are put up to fatten. Cut hay and straw are liberally furnished them in the troughs. These last articles of food are held to be so indispensable for the animal's health that they must always be supplied. Pea straw, when it is to be had, is likewise given cut down, which sheep relish very much. Where there is a number of sheep to be fed, the hay and straw should always be cut by a machine driven either by a horse, or, where the farm admits of the thrashing machine going by water or by horse power, the machinery of either should be made to drive the hay cutting machine. And to these same thrashing machines, a turnip-slicing machine

* Blacklock's Treatise on Sheep.

† In the neighbourhood of Dublin early lamb is raised on a large scale for the supply of the Liverpool market. The lambs have a large allowance daily of cow's milk given them in addition to that which they receive from their dams.

ought to be attached, which would supply the cattle in the straw-yard, and those tied up in the stall, with cut turnips. It is found to be not only healthful for the animal, but far more economical as concerning the provender, not to fit up the stalls or cattle-feeding houses with racks, but to substitute in their place deep, wide mangers; these being filled with the chopped hay and straw, bruised grain, and sliced turnips, there can be no waste. It must have been observed by every one who examines the litter in stables and cattle-feeding houses, that there is much hay trodden under foot. When a rack is crammed with hay, the animal, generally before he begins to eat, pulls out a quantity of it, which, falling down on the ground, he selects from the mass which is most agreeable to his palate; the remainder being rejected, passes into the litter. No hay ought, therefore, ever on a farm to be put into the rack, but always to be cut by the machine into short lengths and placed before the animals in deep mangers. When cut hay with bruised oats (they ought always to be bruised) are put into the manger, the horse feeds with the least waste of provender to his owner, and having soon satisfied his hunger lies down and rests. That cut hay and straw are absolutely indispensable to sheep fed on turnips. These roots being of a succulent, laxative nature, when given to them without any hay, are apt to purge them severely and induce disease. We solicit the reader's attention to the following extract from "Sinclair's Hortus Woburnensis," a work on the "British Grasses," a publication of great practical value to the farmer. He shews in the clearest manner the necessity of supplying sheep with hay, when folded upon turnips.* It is necessary that plants having a bitter

* Sir A. Davy observes, "it appears probable that the bitter abstractive matters of the grasses, are very little nutritive; but probably they serve the purpose of preventing, to a certain extent, the fermentation of the other vegetable matters in the stomach, or in modifying or assisting the functions of digestion, and may thus be of considerable use in forming a constituent part of the food of cattle. A small quantity of bitter extract, and saline matter, is probably all that is needed; and beyond this quantity the soluble matters must be more nutritive, in proportion as they contain more albumen, sugar, and mucilage; and less nutritive in proportion as they contain other substances.

"To these, I may be permitted to add the results of a trial which I made on the *dung* of sheep, that had fed on turnips, as it may afford some information on the nature of turnips as food for sheep.

"1920 grains of the yellow Scotch Turnip, on which sheep were feeding, afforded of nutritive matter 85 grains, which consisted of,
Mucilage 9 grains.
Saccharine matter, or Sugar 73 ..
Bitter Extractive and Saline matters.... 3 ..

"1920 grains of the *dung* of the sheep which had fed on the yellow Scotch turnip, afforded of soluble matter, by means of a large quantity of water, 17 grains, which consisted of,
Animal Mucus and Mucilage..... 3 grains.
Bitter Extractive and Saline matters .. 14 ..

"The most remarkable circumstance here, is the superior quantity of bitter extractive in the *dung*, to that which is shewn to exist in the turnips; but the sheep had hay, on which they occasionally fed in the field, and on examining the insoluble portion of the *dung* (after separation from the soluble parts), nearly one-fourth part in weight consisted of the woody fibre

extractive principle should be supplied, to correct the purgative tendency of the turnip. The plants which compose hay abound in these qualities. With regard to the use of the bitter extract contained in hay, it may be laid down as a well authenticated fact, that it stimulates the stomach and promotes digestion. Turnips contain a large quantity of matter capable of affording nourishment to the body, but yield very little of the bitter principle. In consequence of this, sheep acquire fat rapidly for a time when placed on turnips without hay, but experiencing a want of medicinal bitter, begin with equal rapidity to lose the advantages they have gained. They may, for a few weeks, when on turnips, continue healthy, though no hay should be allowed them. But they will at last fall off. By, however, giving them good hay and plenty of it, they will not be long in recovering their condition.*

(To be concluded in our next.)

QUEEN MARY'S TREE.—This memorable tree, which has braved the blasts of centuries, yielded to the fury of the gale on Monday last. It stood at the east end of the village of Duddingstone, and nearly opposite Lord Abercorn's Park. It was, perhaps, one of the oldest thorn trees in Scotland, and of the greatest dimensions. Its exact measurement we do not at present recollect, but we know that two men, embracing its trunk at opposite sides, could not make their hands meet. It was commonly called Queen Mary's Tree, though it is probable that it was planted before her reign. It formerly stood within a park, but on widening the carriage road, it was brought outside about ten or twelve years ago, and then it seemed on its last legs, several fissures appearing in the trunk, through which the elements of air and water were fast consuming the venerable tree. The road trustees had these fissures filled up with stone and lime, and had it otherwise protected, but the violence of the gale on Monday pulled it up by the roots, laying it along a shattered and withered trunk; and thus another of the memorials of the unfortunate Mary has perished, and in the vicinity of her Holyrood.—*Aberdeen Banner*.

of hay, which evidently had afforded the extra quantity of bitter extractive to the dung.

"The sheep eat of the hay from choice, and not necessity, and it is more than probable that the bitter extractive principle it contained, was, under such circumstances, the most valuable part of its nutritive matter, in supplying the deficiency of it in the turnips.

"It is worthy of observation here, that the leaves, or herbage of the common pasture grasses, contain nearly the like proportion of bitter extract, as that in the dung; the sheep, therefore, in this instance, had taken that proportion of hay, which, combined with the turnips, formed a natural food, or that which had nutritive qualities analogous to natural pasture.

"The dry fibre of the hay or straw given with turnips, may also assist mechanically in correcting the watery, over succulent, laxative nature of the food, in the cold season of the year in which it is given to sheep, when an excess of moisture may be more hurtful than in a warmer season."—(*Sinclair's Hortus Woburnensis, or Treatise on British Grasses, p. 7.*)

* See Blacklock's Treatise on Sheep. It is a work of great merit, containing much valuable practical information on the treatment of sheep. No sheep farmer ought to be without it.

THE DUTY ON HOPS:

TO THE EDITOR OF THE WORCESTER JOURNAL.

SIR,—I think you will be rendering the hop planters an essential service if you will be kind enough to insert this letter in your paper, relative to different opinions held by hop planters respecting a high tax on hops, and a low one. There is about one in every hundred who thinks a high duty in hops will give a high price to the planter: I have made a comparison between the high price on hops obtained when the duty was a penny per lb., and when at the present high duty of two pence; I cannot give you the date when the alteration in the duty took place, but it was early in the French war, when blood money was wanted. I well remember however the time when a Mr. Waddington, a merchant from London, who had the command of a large capital, came to our Worcester market to buy hops, and the prices then were from 8*l.* to 10*l.* per cwt; but from the quantity of money he threw into the market, hops got up to 15*l.* per cwt. Mr. Waddington waited upon Mr. Pitt, then Chancellor of the Exchequer, and told him he might double the duty on hops, as they never would be under from 12*l.* to 15*l.* per cwt. Mr. Pitt took the gentle hint, and laid on this oppressive war tax to assist him with his ruinous war; but how were the predictions of Mr. Waddington verified? In no way beneficial to the planters, for hops in three years went down to 3*l.* per cwt. So much for Mr. Waddington's prediction to enable him to come down to crush the fair trader, and allow him to forestall the market, for which he in the end paid dearly. This completely floors the one planter out of every hundred who would not sign the petition to get the penny per lb. repealed. They say high duty makes high prices; when hops were from 8*l.* to 15*l.* per cwt., then the duty was one penny per lb.; and in three years after, when we paid two pence, hops were at 3*l.* per cwt.; and how is it that hops during the last six years have not averaged in our market more than 3*l.* 10*s.* per cwt. with this high duty? I think this fact makes the few planters' arguments fall to the ground, and the ninety-nine out of every hundred just persons who signed the petition are right, and that the war tax is an oppressive and an unjust tax paid out of capital. Our one planter in every hundred thinks the plantation too large for the consumption, which causes the low prices; but this I deny: the consumers of beer are increased four to one to what they were in 1808, and our plantations are not increased in the same proportion; the cause is obvious to any one: we have had seasons which have suited the growth of hops for many years, quite different from the average of seasons from 1800 to 1820, which were wet and not congenial to the plant, which gave us high prices. I do consider the price of all marketable commodities depends upon the supply and demand, and, above all, the quantity of money accessible to be got at to pay for them. The one great cause of the dearness of hops was, that bankers allowed the trade to draw to almost an unlimited extent in the hop season; now the screw is put on and no such facility given,—we depend upon speculators to invest their money in hops, and if hops are not at a moderate price then we lose that class of customers in the market, which makes the planters speculate upon their own growth. I think, Sir, I have shown you enough to convince any sane man that if a planter pays 100*l.* duty on hops instead of 50*l.*, he loses that sum for ever, as it never can return into his pocket in any way.

Your obedient servant,
A HOP PLANTER.

DUTY ON HOPS.

TO THE EDITOR OF THE MAIDSTONE GAZETTE.

SIR,—Having observed in your paper of last week, a paragraph in which it is advised to apply for a kind of *ad valorem* duty on hops, I think that course would be objectionable, as some machinery must be had to ascertain what is the average price of hops per year; and it would be thought that it exposed the real income of the farmer too much. I would venture to suggest that it would be far better to petition for a reduction of the duty altogether, or at least to the old duty of 9*s.* 4*d.*, for it appears plainly, that the duty is no protection to the Kentish grower against the Sussex grower, as the result of the last years have proved, for although the average price of Sussex hops has varied from 50*s.* to 70*s.* per cwt., yet the plantation has increased in Sussex, and diminished in Kent. Although the Sussex planters must have been losers, yet the duty, as formerly stated by some, has not caused them to desist from planting. I agree with your correspondent that the greater growers are not the most able or willing to pay the duty.

May 4, 1840.

A. Z.

ON THE APPLICATION OF THE MANURE OF COWS.

SIR,—Encouraged with the attention you always pay to matters relating to agriculture, I take the liberty of trespassing on the columns of your interesting Magazine, for information on the best mode of preparing and applying cow-dung as a top-dressing for grass land, hoping thereby that some friend to agriculture, who may be in possession of the required knowledge, may be induced to propagate that knowledge for the benefit of others.

In this neighbourhood many large stocks of dairy cows are kept, which are fed in-doors during winter, and consequently a great quantity of manure is made from them; considerably more than is required for green crops, there being but little of the land in cultivation. There is a general clearing out of this manure from the yards in the month of January; and that which is short enough for spreading is put immediately on the land; but when it is mixt with much straw it is thrown up into a heap lightly for further decomposition, and after lying in this state for a month or so, is applied to the grass.

And now comes the evil for which I want to find a remedy.

If the two following months, namely, March and April, should prove dry, as has been the case this year, there is very little benefit derived from this manure. It soon becomes so dried and hardened that it imparts no more benefit to the land than if so many chips were spread on its surface: and after once getting into this state, it requires an immense deal of rain to dissolve it. Showers have no effect at all on it. I have seen the globules of water remain perfect upon it for a length of time, without the least particle having been taken in, and the sun and wind ultimately dry them up. In fact the ground must have a thorough soaking before it has effect on this manure when once got into this hardened state. We know that when very well mixt into a compost with light earth, this tendency to harden is in a great measure overcome; but it is not always that we have this at command, and therefore I wish to know what other means may be employed to the same end.—Would a mixture of salt have that effect? If so, in what proportion should it be used?

An answer to this enquiry, through the Magazine, would be thankfully received by, Sir,

Your obedient servant,
A TENANT FARMER.

Bangor, near Wrexham, North Wales,
5th May, 1840.

ON THE FORMATION OF WOOL.

We quote from 'The African Colonizer' the following passages relating to the formation of wool, which will be read with interest just now when public attention is particularly directed to the process of felting woollen cloth.

Most animals have both wool and hair as their clothing, (1) but the preponderance of the one over the other differs materially in various animals, and may be altered by climate, and other influences. The sheep, in our portion of the globe, the llama of Chili, the yak of Tartary, the camel &c., are clad, almost exclusively, with wool. Abundance of wool is mixed with the hair of the deer; even the tiger and the seal are not destitute of it; and it abounds in the fur of the hare, the beaver, and the chinohilla and others; (2) but is always overlaid by the hair. From the earliest times, wool has been known to possess the property of felting, and felted cloth is of great antiquity. Pliny observes, that wool, of itself, if driven into a felt, without spinning or weaving, serves to make garments; and that if vinegar be used in the working, such felts are proof against the edge, or point of the sword, and are capable of arresting the progress of fire. (Lib. viii.) Mantles and counterpanes of felt were used at Rome. (3) Now, hair, however long or delicate it may be, does not possess the felting quality. In what, then, consists this property in the one, and to what is to be attributed its absence in the other? And here in justice, reference must be made to Mr. Youatt, (see his work on the 'sheep'), to whom the credit is due of demonstrating the true characters of wool, the principles of felting, and the difference between wool and hair.

Many are the theories upon which the philosophers have attempted to account for the felting of wool. The attraction of cohesion; the elasticity of the fibres, bent in every possible direction, and prevented from returning to their original length by the adhesion of other fibres; the property, which certain hairs and vegetable filaments have, of attaching themselves more and more to each other, in proportion as the fabric into which they are united, is beaten,—the fibres entangling each other in circlets, and, by their elasticity, striving to return to their original condition; these and modifications of similar theories, were accepted as a sufficient explanation. M. Monge was the first who ventured to assert that a feathered, or barbed edge, must be the structure of the surface of wool; that the surface is formed of lammellæ, or little plates, which cover each other from the root to the point, pretty much in the same manner as the scales of a fish cover that animal from head to tail, or like rows placed one over another, as is observed in the structure of horns.' On this theory the truth of which M. Monge assumes, he explains the mechanism of felting, as accurately as though he had seen the serrated edge of the wool. (4).

M. Monge, however, did not see the peculiarity in question, and it was reserved for Mr. Youatt to demonstrate it. (5) The true cause of the felting property of wool, and, at the same time, its distinguishing character, when contrasted with hair, consists, as ascertained by microscopical experiments, in its serrated structure externally. When viewed through a microscope of great power, and as a transparent object, the fibre of wool assumes a ribbon-like form, with serrated edges; but these serrations, when the fibre is viewed as an opaque object, are found to result from the presence of a

succession of inverted cones encircling a central stem, the apex of the superior cone being received into the cup-like base of the inferior one: and each cup-like cone has projecting and indental edges, directed from root to point. These conical, or cup-like circlets, are farther resolvable into distinct scales, or leaves, set regularly around the central stem, and varying in number, size, and degree of projection, in the wool of different animals. In some instances these scales are pointed, in others round. In the wool of the bat, these circlets are so decided as to produce the appearance of a series of cups placed one in another, and having indented edges. Though hair is covered with scales or rugosities, it has no serrations, or tooth-like projections; the hair of the tiger is covered with scales, like those on the back of a sole; while, in the wool of the same animal, the serrations are distinct and numerous, as they are, also, in the wool of the bear, and of the Italian wolf-dog. The human hair, as ascertained by Mr. Gill, is of a cylindrical form, and covered with scales, or rugosities, but without serrations. (6)

The engravings from Mr. Youatt's work serve to illustrate the microscopic characters here detailed, by which hair and wool are respectively distinguished.

The wool of the rabbit is fine, with sharp, angular serrations, to the number of 2880 in the inch, 'being 160 more than in the highly valuable and felting Saxon wool.' The fibre, however, has fewer curls. The hair varies from 1,250 to 1,300 part of an inch in diameter, and is covered with a scaly incrustation, but cannot be said to be serrated.

In the seal, the wool is abundant beneath the compact hairs, and is exceedingly fine, but the serrations are few, and far apart; the hair, having about nine times the diameter of the wool, is beautifully covered with scales, but there is not the vestige of a serration.

In the wool of the bear, which is very fine, the serrations were found to have a curious character; 'they resembled so many spires, projecting at irregular distances, and at an exceedingly acute angle.' In the Italian Wolf-dog (which has a considerable portion of short wool beneath the hair,) the serrations of the wool were found by Mr. Youatt to be 'superficial, and irregularly placed; some of them resembling small spines, and others looking like rounded prominences.' When viewed as an opaque object, the cup appeared to be 'composed of two, sometimes three, leaves, with rounded extremities.'

The wool and hair of the Tiger are then represented. The wool is beautifully fine; it is only the thousandth part of an inch in diameter; its serrations are likewise numerous, amounting to 2560 in the space of an inch. The hair is covered with scales, resembling those on the back of a sole, but with no serrations.

The differences, then, between wool and hair, according to Mr. Youatt, are as follow:—The fibre of wool is crisped, or curled, the curls increasing according to the fineness and felting property of the wool; and, in addition to this, it is decidedly serrated; whilst hair, though sometimes curled, but in a very limited degree, in comparison with wool has its edge only scaly, or rugose, and never truly serrated; and hence it is that hair though it will entangle and harle, to a certain extent, will not felt into a compact mass.

1. The blood-horse of England is destitute of any particle of wool; but the shaggy pony of the moun-

tains of Wales, or of the black Shetland Isles, is half clad with it.

2. "My opinion," says Mr. Plint, "is that, with few exceptions, the covering of quadrupeds is a mixture of hair and wool, varying greatly in their proportions to each other. Let us consider them in their native state: they are exposed to the vicissitudes of the seasons, and therefore need not covering at one time, to throw off the influence of the sun's rays, and, at another time, to retain the animal warmth, when the surrounding temperature would otherwise rapidly withdraw it. Hair and wool are bad conductors of caloric and admirably adapted for both purposes, and they exist in actual and relative quantity according to the altered situation and wants of the animal. Thus, in summer, the fleece of the Arctic Hare is thin, as I believe is that of the Argali; in winter, a fine wool fills up the interstices, between the hair, and protects the animal from the inclemency of the weather. Here is an admirable provision for the wants of animals generally; but we should stop short of the exact adaptation of the fleeces to these wants, if we did not remark how necessary it is that the wool so indispensable to the retention of the warmth of the animal should be protected by a coat of long smooth hair. Just imagine the Argali, or the Hare; or, to instance animals of the carnivorous genus, the Sable, or Polecat, clothed with wool only, and what a miserable plight the poor animal would soon be in! The fleece would prove a constant impediment to its movements among underwood, if indeed it were not entirely stripped off the back of the animal." See Youatt on the "Sheep," p. 57; published by the Society for the Diffusion of Useful Knowledge.

Strong and thick felted covering, dyed with a pattern of various colours, has been found on the body of a mummy from Thebes.

4. "The workman," he says, "presses the mass with his hands, moving them backward and forward, in various directions; this pressure brings the hairs against each other, and multiplies their points of contact. The agitation gives to each hair a progressive motion towards the root; but the roots are disposed in different directions, in every direction; and the lamellæ of one hair will fix themselves on those of another hair, which happens to be directed a contrary way, and the hairs become twisted together, and the mass assumes that compact form which it was the object of the workman to produce. In proportion as the mass becomes compact, the pressure of the hand must be increased, not only to make it closer, but also to keep up the progressive motion and twisting of the hairs, which then take place with greater difficulty." Thus near did M. Monge arrive at the truth.

5. Mr. Youatt thus announces his discovery: "On the evening of the 7th of February, 1835, Mr. Thomas Plint, woollen manufacturer, resident at Leeds; Mr. Symonds, clothing agent, of Cateaton-street, London; Mr. T. Millington, surgeon, of London; an esteemed friend, Mr. E. Brady, veterinary surgeon, at that time assisting the author in his practice; Mr. W. H. Coates, of Leeds, veterinary pupil; M. Powell, the maker of the microscope; and the author himself, were assembled in the parlour. A fibre was taken from a Merino fleece, without selection, and placed on the frame, to be examined as a transparent object. A power of 300 (linear) was used; and, after Mr. Powell, Mr. Plint had the first ocular demonstration of the irregularities in the surface of the wool, the palpable proof of the cause of the most valuable of its properties, its disposition to felt. The fibre thus looked at, assumed a flattened, ribbon-like

form. It was of a pearly-grey colour, with faint lines across it. The edges were evidently hooked, or, more properly, serrated;—they resembled the teeth of a fine saw. These were somewhat irregular in different parts of the field in view, both as to size and to number. The area of the field was one-fortieth of an inch in diameter. By means of a micrometer, we divided this into four, and we then counted the number of serrations in each division. Three of us counted all four divisions; for there was a difference in some of them. The number was set down privately, and it was found that we had all estimated it at 15 in each division. Having multiplied this by four, to obtain the whole field, and that by forty, the proportionate part of an inch of which the field consisted, we obtained, as a result, that there were 2,400 serrations in the space of an inch, all of which projected in the same direction; viz., from the root to the point." The diameter of the fibre was ascertained to be 1-750th of an inch.

"We next endeavoured to explore the cause of this serrated appearance, and the nature of the irregularities on the surface, which might possibly account for the production of these tooth-like projections; we therefore took another fibre, and mounted it as an opaque object." After some difficulty, at length Mr. Powell succeeded; and we were presented with a beautiful glittering column with lines of division across it, in number and distance seemingly corresponding with the serrations that we had observed in the other fibre, that had been viewed as a transparent object. It was not at once that the eye could adapt itself to the brilliancy of the object; but by degrees, these divisions developed themselves, and could be accurately traced. They are not so marked as the inverted cones which the Bat's wool presented, but they were distinct enough; and the apex of the superior one, yet comparatively little diminished in bulk, was received in the excavated base of the one immediately beneath; while the edge of this base, formed into a cup-like shape, projected, and had a serrated, or indented edge, bearing no indistinct resemblance to the ancient crown. All these projecting edges pointed in a direction from root to point.

6. Dr. Goring (see *Brande's Quart. Journal*, 1826, p. 433) describes the appearance of the hair of the human head, beneath the lens of a microscope, as being "indented with teeth, somewhat resembling those of a coarse round rasp, but extremely irregular and rugged; these all incline in one direction like those of a common file; viz., from the origin of the hair towards its extremity." "It is singular," says Mr. Youatt, "that although nine years have passed and the microscope has been considerably improved, since Dr. Goring observed this structure of the hair, and almost every one, who possessed an instrument of much power, has been eager to gaze on this new discovery, no person has been so fortunate as to detect a single serration on its edge." A truly serrated surface is, according to Mr. Youatt, the character of wool only.

Labour well applied is always productive of some profit, and these who spare it act on a false principle of economy; but the best and most judicious method of employing labour and time is the most important of all subjects to the real economist. Many persons learn this method from long experience, and it is true that the tact and coup d'œil thus acquired is peculiarly accurate. But it may be acquired much more promptly and definitely, by the observation of cer-

tain principles from which a theory of action may be deduced without serving a tedious and expensive apprenticeship to experience.

It is far more difficult to apply labour judiciously to agriculture than to manufactures. For the labour which is required for some particular kinds of produce, lasts but a very short time, and is then suspended for a much longer period, during which the farmer depends upon the operation of nature to bring the produce to perfection, and awaits the proper season for gathering it in. After each species of grain has been sown it requires very little, or no attention for some time : whereas in the formation of any kind of fabric, the labour must be continued from the very commencement until the completion of it. In order therefore, that the farmer may make the very best possible use of the force which he has at his command, he should endeavour to arrange the succession of his crops in such a manner that every hour should be devoted to some preparatory and necessary operation. It is also necessary that he should select the produce so as never to have more operations in hand at once than he can accomplish by means of the force which he has at his disposal, or, which is within his reach.—*Von Thaër*.

ON MARL.

Marl, (*mergel*, Dut., *mery*, Sax., *marga*, Lat., from *marceo*, *quod est terra marcida*, *putris et solubilis*, or *μυρον*, *unguentum*, ointment, or drop, and *γῆς*, earth, *quod est unguentum terra, vel ex, μαργαρον*, *quod splendat*, or from *marg*, Ger., *medulla*, an *adeps* or preparation, or fat marrow, *dimin* : *margula*), is a fat, unctuous substance, composed of clay and chalk mixed together in a peculiar state of combination, and forms a calcareous earth, or carbonate of lime. In geology, marl is found in the tertiary formation, resting upon the gypsums, and alternating with it : one bed is white and calcareous, and contains silicified trunks of trees, and several species of plants and fresh-water shells ; the other beds are argillaceous, and of great thickness, and sometimes contain balls of celestine or sulphate of strontites ; thick beds succeed, the uppermost of which contain great quantities of oysters. Marls lie in the second and third beds of this formation, and the former is called a fresh-water formation from its containing few other petrifications than those of fresh-water, and land animals ; the latter concretion joins with the sands and sandstones, and contains marine shells. The fourth and last bed of the formation is a very large one of the fresh-water denomination.

In the natural history arrangement of minerals, marl forms the eleventh sub-species of "limestone," or rhomboidal calcareous spar, which is the second species of the genus "limestone," and the sixth of the order "haloide," which is the first of the second class of the arrangement, having no peculiar sensible taste, no metallic lustre, streak not changed in colour, and the sp. gr. above 1.8. It is divided into two kinds, earthy marl and indurated marl. The latter, or *marga schistosa*, not crumbling in the air, is sometimes spotted reddish or brownish in the rents, and marked with dendritic delineations ; but most commonly smoky-grey, bluish and yellowish grey, in colour ; and much resembles compact limestone ; occurs massive in angular or vesicular pieces, and in flattened balls, and contain animal and vegetable impressions, internally and externally dull and only

glimmering with foreign parts, which may be owing to the presence of particles of sand and mica ; fracture earthy, and passing into splintery, uneven and conchoidal, mostly thick and straight, slaty texture, generally slaty where there is little clay, and not crumbling in the air, fragments angular, blunt, tabular, discoid, laminar and slaty, opaque, yields to the nail ; streak greyish white ; feels meagre, is easily frangible, and rather brittle ; it effervesces briskly with acids, intumesces before the blow pipe, and melts into a greenish black slag : it contains

Carbonate of lime	50
Silica	12
Alumina	32
Iron and oxide of manganese	2
Loss	4

100

Sp. gr. 2.365 : 2.550 : 2.300 : and 2.700.

It occurs in the coal formations, in the new formations that rest on chalk, and in the secondary flint limestones, and also in the flint trap, though not fully understood, and often contains iron pyrites and garnets ; it is found stratified in various parts of the continent of Europe, and is met with in England and in Scotland, in the coal formations, and in the secondary formations that rest on the chalk, in the south of England.

In marls, where the calcareous earth predominates, the substance is called "calcareous marl ;" where aluminous earth is most abundant, it is called "clay marl ;" and "ferruginous" where there is a considerable mixture of the oxide of iron. The latter kind forms "septaria," or "ludi helmontii," found in curious spheroidal concretions that vary from a few inches to a foot and a half in diameter, and are mostly disposed in a regular manner in beds of marl ; when broken in a longitudinal direction, we observe the interior of the mass presenting to view a number of fissures, by which it is divided into more or less regular prisms, of from three to six or more sides, the fissures being often empty, but more generally filled with granular limestone in a crystallized state. This singular production is attributed to the effects of contraction, arising from exsiccation ; but a great difficulty lies in accounting for the uniformity of the fissures, their being confined to the interior of the balls, and their containing substances most likely to be injected externally or from without. These marly balls, or "septaria," abound on the continent, and in the Isle of Sheppey, in Kent, they are very numerous and large, and contain heavy globular spar, with diverging fibrous concretions. They also occur in Derbyshire, and are of a bluish grey colour ; and also in Durham, where the fissures separating the prisms are filled with quartz, and the quartz "septa," freed from the marl, represent the figure of a honeycomb. From these "septaria," that invaluable material for buildings under water, called "Parker's cement," is manufactured.

A variety of indurated marl forms a very beautiful stone called "Florence, or ruin marble," often reckoned a compact limestone. It is called "ruin marble," from the ferruginous infiltrations in the fissures of the substances presenting a number of varied colours when viewed at a distance, resembling the ruins of walls, castles, and bastions, with a representation of landscape perspective. A nearer approach dispels the illusion, which arises from a number of irregular spots, superficial or penetrating the mass. It is very dull in fracture,

and argillaceous in composition, and consequently never used in architecture, but is merely sawn into slabs. Some kinds of it exhibit groups of trees and shrubs, and beautiful arborescent delineations, from an arrangement of black "dendrites," and hence called "landscape marble," and a fine variety is found near Bristol in large oblong pieces, and called "Cottam marble," representing shrubs, trees, and grottos, from blackish brown spots and veins arranged in a dendritic form.

Goodes of marl are found in Italy, and in the south of France, and mostly owe their composition to the destruction of a nucleus originally lodged in the centre; they are either empty or drused over with crystals, mostly of quartz or calcareous spar.

The name of "ludi helmuntii" is also given to those imitative figures or forms frequently assumed by solid pieces of indurated marl, which have got the names of priapolites and zingebrites, or ginger stones.

Bituminous marl slate, "*marga bituminosa*," is allied to marl, being a carbonate of lime united with iron, bitumen, and alumina. It is of a brownish black colour, occurs massive, shines and glistens, slaty and greasy, streak shining and resinous, opaque, soft, meagre, sectile, and frangible; sp. gr. 2.631, to 2.690. It occurs on the continent of Europe, and in the Cordilleras of South America, in fletz limestone, and contains minerals, as copper ore, pyrites, and glance; also blue, green, and native copper; and contains impressions of fishes and plants. It is not found in Britain. It burns before the blow pipe, with a thick dross. The varieties rich in copper ore are wrought as ores of the metal, and bituminous marl slate when decomposed in the air forms an earth highly injurious to vegetation. In this slate remains of fishes have been found converted into coal, in very contorted and convulsed forms, indicating the sudden catastrophe of their destruction, their substance being almost wholly converted into copper pyrites, by some thought to have been the cause of their death, as their number in the slate is generally proportionate to the quantity of copper it contains. In a hard schistose marl, in that great natural curiosity, Monte Bolca, near Verona, in Italy, there have been recognized 105 different species of fishes, belonging partly to all the different seas known, and to fresh water lakes and rivers. This slate passes into indurated marl, and into stinkstone.

Aluminous and calcareous marls are used for the purposes of mortar, and in pottery, and in smelting iron, but the principal use is in agriculture.

Earthy marl, or "*marga terrea*," is of a whitish colour, or yellowish grey, or yellowish white, and sometimes smoke grey, these are the colours when dry; when moist in its bed it is generally blackish brown or brownish black. Some varieties are generally of a brown colour, and emit a urinous smell, and by some considered an earthy stinkstone. The colours are usually lighter than of indurated marl. It consists of dusty particles, dull, loose, or feebly cohering; feels fine, rough, or meagre; soils slightly, and is light; mixed with mica, gypsum, or sand, and with the latter fusible into glass; sometimes contains iron, but very rarely other metals; contains 60 to 80 per cent. of mild carbonate of lime, remainder of alumina, bitumen, and silica; sp. gr. 1.6 to 2.4. It effervesces strongly with acids, and when dry gives out a strong urinous smell, but loses that quality by exposure. It occurs in strata, and in beds in the fletz gypsum, and limestone formations, and

along with stinkstone, and in sandstones, and often immediately under the vegetable earth, and abounds in many places of the continent of Europe.

The two kinds of marl pass into each other, the earthy being considered to be produced by the decomposition of the latter, but the two kinds do not always accompany each other. The component parts of marl are so minutely divided as to be invisible to the naked eye; from this circumstance, and from their containing both fresh and salt water organic remains, and from the fossil structure, it has been conjectured that they have been produced from the detritus of other substances, and that they have subsided from a liquid state. This supposition is strengthened by the circumstance of the substances occurring in the fletz or secondary strata. They are soft, opaque, earthy, light, and miscible with water by agitation, soluble in acids with effervescence, harden in the fire, and vitrify in a strong heat; and to constitute true marls the substances must contain as much clay as to fall into a powder in water, and crumble into minute particles by exposure to the air, generally showing a hoary congelation to the rays of the sun. The quantity of calcareous matter varies from two-thirds to four-fifths, which may be separated by most of the acids, which will wholly dissolve the substance and leave a residue of clay, which is composed as usual of alumina and silica. Porous marl, or "*marga porosa*," is found in various parts of Britain and on the continent; whitish or grey coloured, indurated, porous, and breaking into indeterminate fragments. It becomes reddish when burnt according to the quantity of oxyde of iron it contains, and occurs mostly at the bottom of waters that are or have been stagnant.

Marls, in agriculture, are divided into stony, sandy, clayey and shelly, according to the appearances it assumes in different situations where it is found at various depths under the ground. The first kind is called "rotten limestone," and is thought to owe its hardness and slaty or laminated texture to the presence of sand along with the calcareous and argillaceous ingredients. It is slow in operation, but lasting, and very favourable for the production of grass after a long period of time. "Sandy marl" is most frequent in Ireland, in pits of limestone gravel, and is called limestone sand. The colour is brown, blue, or black, sometimes like lead; contains more sand than clay, and consequently not unctuous, and does not adhere to the tongue, feels gritty and slowly crumbles and moulders down when exposed to the air. It does not much effervesce with acids, as the sand amounts to about 75 per cent. and consequently chalk and sand predominate; but on clayey stiff soils it has much improved the texture of the land when liberally applied. "Clayey marl" is found of different colours, yellow, blue, red and brown, occasioned by the substances to which it has been exposed, and by the subjacent and superincumbent formations—as much as 60 to 80 per cent. of clay being found with 8 to 10 of silica, and the remainder being carbonate of lime with signs of iron. It contains more clay than other marls, and consequently possesses a greater power of absorbing and retaining moisture—has a soft unctuous feel, and in the original moist state is flexible like a paste, but dries and crumbles on exposure; its effects on all light and thin soils, sands, gravels and loams, are very great, as the portion of clay adds to the bulk and consolidation, and also benefits the land by moisture. "Shelly marl" is generally

found in places that have been covered with water, and is supposed to have originated from testaceous animals, being composed of shells connected into calcareous earth, more or less refined and pure, according to the attrition and decomposition they have undergone during a long period of time, and according to the quantity and quality of the substances mixed with them by the decomposition of earthy and muddy matters left by the sediment of the waters. This kind of marl contains more calcareous matters than the others, generally more than ordinary limestone. Most marls effervesce in acids when fresh; after burning the ebullition ceases. But several varieties are used that show no affection by acids, and are found to be great improvers of land, and have been long celebrated as manures. Clay marl effervesces feebly and hardens in the soil, while the more calcareous sorts dissolve into powder, and all the marls are easily vitrified and crumble by exposure according to the solidity of texture, and when burnt, by the attraction of moisture, and feel greasy when they contain particles of mica. Marls are generally found in a moist state, especially the argillaceous sort, and crumble by exposure, which property distinguishes them from lime which is not altered; after calcination, lime falls into a powder by the action of air and water, but burnt marl suffers no change, and marls exposed for years retain the same properties as when newly dug.

Ancient records inform us that marls have been very early and extensively used in Britain, and they are yet applied in some places, though in a great degree superseded by the use of lime, which is rendered by burning much lighter and more convenient of carriage, while the crude and heavy state of marl, and the great quantity required for an effectual application, confine it to the localities where it is found. For the sake of conciseness in practical purposes, marls may be divided into two kinds—shelly and earthy—minute accuracy will make many subdivisions, but these two classes will contain the different kinds in sufficient distinction according as the marls contain more earth or lime in their composition.

Shell marl is generally found under mosses, and in the bottom of lakes, soft and of a bluish white colour, and seems to be a natural deposit where water has been stagnant. The deposition usually partakes of the nature of the surrounding earths, and may properly be considered a compost of organic matters with earths and calcareous materials reduced without the action of fire, and for this reason it would seem to constitute a manure of superior quality. It often occurs in ponds and in land-locked bogs, on the sides of hills and on the banks of rivers, formed by the accumulation and decomposition of wilks and periwinkles, and also of bivalves, lying in beds of different thickness, running horizontally but seldom of great extent. In Ireland, it lies sometimes within two or three feet of the surface in low bogs, and in other places at a depth of seven to nine feet. To reach the true marls, several strata are pierced, as turfy earth, gravel, moss and fossil wood scittle by the spade, and a vegetable stratum of leaves, seeds and berries; then clay with shells used as marl, and then the true marls in beds of four or more feet in thickness, and often contains horns of deer. Marls, from below mosses, have been found to contain as much as 84 per cent. of pure lime, which is more than

is found in the purest limestones; in other trials shell marl was found to contain

Lime.....	41.25
Carbonic acid.....	32.
Silica.....	14.
Argil	4.
Oxide of iron.....	2.05
Inflammable matter.....	2.
Loss	4.70

100.00

In such situations, the depth at which the marl is found prevents much use of it, and the weight of the substance and the quantity required, renders the carriage always very expensive.

Clay marls are found under mosses and in low wet places, at the foot of hills and in the valleys between them. The composition and quality varies much, from 15 to 40 per cent. of calcareous matter is stated as an average, and the remainder of clay and sand; but there are often found mixtures of sand, loam, clay and chalk, in different quantities, according to the animal, vegetable and earthy matters which abound in the locality, and which have been collected and decomposed together. Separate and distinct beds of clayey and sandy marls have been found alternating with clays and limestone, of which clay is the undermost stratum; the marl being of very different colours as it has been exposed to the elements composing and surrounding it, the redness showing the presence of iron, whiteness that of calx, the blue and yellow marking the clayey composition mixed with other substances. It is sometimes found very hard to dig, with lumps of chalk and limestone in it, lying under stiff clays and low black grounds, and very compact and greasy, and of great value as a manure on sandy lands; it is also found breaking into lumps like dice, or flakes like lead ore of a reddish colour, and smooth on the surface, quickly crumbles and of good quality. Other kinds are found so soft and unctuous as to be delved and cut out by the spade; and slate or flag marl of a bluish colour usually found on the sides of hills and rivers, is found to be very good and lasting, and it very easily dissolves and falls down, very readily by the action of rains and frosts. A mixed marl has been found to contain—

Fine sand.....	36
Clay of a soapy kind.....	44
Mould.....	5
Carbonate of lime.....	14
Gypsum.....	1

100

The mixture of the particles of the different ingredients found in earthy marls, is so minute and fine, that not only the eye, but the microscope, fails to discover the constituents of any of the substances, and chemical analysis only is able to separate and detect them. Mixtures of clays and lime in alternate layers have been recommended and employed to produce an artificial marl; but the properties are wanting, and the true character of marls, that of crumbling by exposure, for all calcareous earths are not marls. We are totally ignorant of the natural process of composition, and we may very justly suppose that that composition consists in parts and qualities unknown to us, and which we cannot imitate. The operations of art fail when brought into competition with the modes of working adopted by Nature—the combination and resolution of rocks,

stones and earths into each other, which goes on incessantly, not to mention the changes of the animal and vegetable worlds, have never been approximated in the most distant degree by the labours of man; mortars and cements are a resolution and combination of a kind; but though the original constituents be known, and though they be again applied in the same proportion, we cannot produce the original substance—for with powdered lime, water, and carbonic acid, and the other ingredients in the due proportions, the limestone will not be composed by any means that we can adopt.

Marls much abound in the county of Norfolk, and a kind is found called "dove marl," like pigeons' dung, and of very excellent quality. The chalk marls of that county contain about,

85 grs. of chalk.
10 of sand.
5 of clay.

100

It breaks readily in the air, and incorporates easily the soil—falls in water but is not dissolved in it, and burns to lime with fire, and loses more than one-third of its weight and is used as chalk limes for manure and in building. The clayey marl contains—

clay 50 grs. with some iron.
43 of impure chalk.
7 of sand and granular fragments.

100

The proportion of clay shows the utility of this marl for light soils. The chalks of that county are also very pure, containing 98 per cent. of pure lime.

The marls are reckoned good when they feel greasy and become friable when dry, and the land above them is of good quality, and red, blue and yellow veins are reckoned the best colours. Marls contain no alkaline salt, as they impart no quality, smell, or taste when digested and boiled in water, and have nothing soluble in that element.

Clay has been found of a soapy nature, and is often mistaken for marl; but it has proved hurtful to vegetation from containing sulphur and other mineral substances; and in such cases, a chemical examination of it is necessary before application. Marls are known by crumbling into small pieces by exposure, by the particle of dry marl crackling in the fire like salt, and by throwing up bubbles to the surface of the water in which it is covered, and by gradually dissolving and forming with the water a soapy substance like a paste, and not unfrequently of a liquid nature, the marl remaining dissolved and suspended in the water without any coagulation. But water alone will produce bubbles when poured on certain dry clays, and it is hence recommended to subject marls to water for a time before being tested by an acid. A more correct method of distinguishing marls has been mentioned in banishing the fixed air from a certain quantity of the substance by applying muriatic acid till the effervescence ceases; the loss of weight shows the quantity of air expelled, and the remainder is earth. The quantity of calcareous matter may be ascertained by dissolving the marl in muriatic acid, diluting the liquor with water, passing it through a filtering paper, and then precipitating the calcareous earth from the clear liquid by a solution of some fixed alkaline salt.

Marls much abound in the eastern and western

counties in England and in many parts of Scotland; where the beds are shallow and the presence of it suspected, time and accident, or intentional search, have discovered the substances; where it lies deeper, the boring rod is the surest guide, the supposed indication of its existence by the growth of "*Tussilago farfara*" being about equal in weight with the notion that plants of the "*Chrysanthemum segetum*," show that land requires marling to extirpate the plant, and that "*Triticum repens*" is considerably checked by an application of that fossil. Pits are opened with a sloping entrance on the farms and localities where marl is found, which is dug and conveyed by carts to the lands where it is intended to be applied. The quantity used on an acre of land varies from 10 to 100 loads of two and three-horse carts of 30 to 40 bushels each, and from 40 to 60 loads may be taken as an average application, and often adds an inch to the staple of the soil—the quality of the land, and of the marl, and the expense of the article will have the usual relative influence, and the expense will also vary according to circumstances from 2*l.* to 6*l.* an acre. It is applied on land after tares for wheat, and in a clear fallow, and as a preparation for barley and turnips, where the shallow furrow of the last ploughing is very suitable for covering the marl. A better application is recommended on clover leys intended for wheat, where a period of six months before the land is ploughed, will be of great service in crumbling the marl by the alternations of frosts and thaws, and for securing an even and level distribution over the surface.

An objection arises to this method that the marl has not had sufficient time to fasten upon, and adhere to the ley; it lies loose, and is thrown to the bottom of the furrow, without a chance of exerting any influence from not being mixed and incorporated with the soil. In the application to barley and turnip lands, this objection does not happen as it will be blended with the pulverized soil, by ploughing and harrowing; but there is not a sufficient time to dissolve the marl for mixing, unless it be dry and exposed and turned over in heaps previous to the application, which will add to the expense of the manure. A more effectual and more economical method is used, by laying it on grass lands in autumn, and during the first months of winter when the grass is of little value, and when the changes of weather will effect the decomposition of the marl by the time the grass shoots up in the spring. It will thus ensure a regular distribution over the surface; and the bush harrow and the roll being afterwards applied, the particles will be well reduced and pressed to the roots of the plants. The crop of grass will be greatly improved, and when the land is ploughed for oats in the following spring, the marl will be thoroughly matted with the flag, and the grassy sward thus raised will much promote by its decomposition the subsequent fertility of the land. This mode is preferable in affording time for the crumbling of the marl; the application to turnips and barley in the spring admits of finer blending, provided the reduction of the substance can be accomplished, which may be done by exposure on the land probably between the two last ploughings, if favourable weather happen, and where the composition of the marl itself favours the speedy dissolution. This result may be much assisted in the spreading, and by going over the work with mallets and breaking the lumps, in the same manner as chalk. In whatever way it may be applied,

it is indispensably necessary that marl be reduced as fine as possible, by spreading and breaking the lumps, by rolling and harrowing when dried after rain, and ultimately ploughed into the land with a shallow furrow, and will thus be intimately mixed with the soil by the future operations. Some marls crumble to powder immediately on exposure, or very soon after; others will require the vicissitudes both of the summer and winter seasons, and also some attention in assisting the action of the weather by breaking, harrowing and rolling.

Marl being a carbonate of lime in a peculiar state of composition, produces effects similar to that substance, but requires to be applied in much greater quantity. Though it is a rich manure, it contains no salts, and is supposed to contain a portion of oleaginous matter, and to be an absorbent earth composed of clay and limestone. The chemist refers the whole benefit to the action of his favourite calcareous earth operating as a stimulant, and that the value of marls is in a direct ratio to the quantity contained; but marls are found with little or no calcareous earth in their composition, and when applied in equal quantities, they have produced similar results. The chemical agriculturist adopts the action of calcareous matter, and joins the bulk or addition which the soil receives by the application of the substance, and to the change it creates in the texture and quality of the soil, by mixture and mechanical action, from the mucilaginous nature it contains derived from animal exuvæ. And they are finally driven to the very reasonable conclusion, very useful at all times, ever at command and always available, that the benefits may be produced by the joint action of these supposed modes of operation. If the component parts of any marl, the clay, sand and calx, and the other ingredients, were spread on land in the definite proportions, separately or mixed by any process we may adopt, and multiplied by the quantity usually applied on a given extent of ground, the effects derived from true marls would not be produced, and on such points, Nature laughs to scorn our attempts and speculations. The extremely minute blending of the ingredients of marl has been supposed to constitute the fertilizing quality, each particle having the power of exerting its peculiar property on the soil and on each other, and of retaining or giving out the substances they may form that are favourable to vegetation by the different agencies and combinations. The clay imparts moisture to the sandy parts, and the sand prevents the clay from being too adhesive, and thus the respective qualities are exerted advantageously on each other. An oleaginous nature has been discovered in the composition, arising from the mixture of the substances, and of animal and vegetable matter, and to this property much of the fertility of marl has been attributed. Marls are supposed to be derived from the ruins of the primary and secondary rocks, worn down and carried about, agitated and deposited without any relation to the laws of specific gravity; animal remains are found at considerable depths, and even stones of great weight are met with, where no rocks of the same, or of a similar kind, are known to exist in the surrounding locality, or in the adjacent geological formations. Fire wholly changes the nature of bodies subjected to the violent effects of its influence, and gives them qualities they did not before possess, and banishes others, which they never afterwards recover. Decomposed lavas are exceedingly

fruitful and the heat of volcanoes produces the most luxuriant vegetation in places within its reach, and it has been fancifully conjectured that marl may retain some of the qualities which its constituent substances acquired as rocks by the igneous agency of their production. Such conjectures amuse the speculative, and interest the curious, but convey no information on the quality of marls or its effects when applied on different soils; on these points we must turn to experience, the true science of the art.

On all heathy lands that have been broken up for improvement, the effects of marl have been great, and on sandy lands generally, and on sandy loams, the applications have been very beneficial, while on raw and damp loams, reports have been less favourable, from the marls attracting moisture, and thus increasing the poachy looseness of the soil. Clays are also much improved by marls when applied in large quantities, but the due effect supposes a somewhat similar pulverization of the clayey mass in order to facilitate the fertilizing mixture of the substances, an assimilation not easily, or rather incapable of being produced on tenacious and hardened clays. Practice has directed the application of marls on all light soils, and the use of sandy and shelly marls on heavier lands, but all these substances have been found useful on any soils when judiciously employed. The hurtful effects of marls have been occasioned by an avaricious use of the plough, and to the frequent sowing of corn crops, and the evil has been completely remedied by the adoption of the alternate system of farming. The effervescence of calcareous bodies with acids, shows the presence of the substance but not the quantity; the ebullition will vary according to the strength of the acid, and the compactness, penetrability and other latent qualities of the calcareous bodies themselves. It may be more advantageous to apply marls gradually and at different times, than in very large doses, which in some particular soils might produce too much looseness, and prove hurtful. Marls are often made into composts with earth and with dung, either in layers in the heaps, or in bottoming the fold-yards, when it will be soaked with the juice from the yards, and afterwards mixed with the mass. It has been thought that such a preparation has produced effects when marls have failed; but very probably a supposition has usurped the place of a just and rational conclusion. Rules that have become general from received and very often false opinions, have deterred many persons from using marl, as being hurtful in a great or small quantity, and from land that was once marled not bearing a repetition till after a certain number of years had elapsed, from increasing the dampness of clammy loams, and the openness of light lands, and in some cases producing no effects at all. On coarse heathy pasture, an application of marl produces the usual effect of calcareous matters by banishing the rough foggage, and substituting a close sward of finer grasses.

This result will be obtained from the application of many other substances as well as from the calcareous, provided they be properly prepared for the purpose intended, and applied in sufficient quantity, and the subsequent treatment on arable lands be judicious and well timed. On light soils that are newly broken up for tillage, marl has had and will have great effect, as the land will contain a quantity less or more of vegetable matter; the subsequent benefits will depend on the mode of management that is adopted, if it be scourging or

improving. The desire and need of immediate gain has produced the effects complained of as having followed from the use of marl, which is now restricted in many places by positive agreement.

In all such cases one thing must never escape the memory of the farmer, that land must be fed with animal and vegetable matters by every possible means; and in the case of light lands, that constant or too frequent cropping with cereal plants will infallibly exhaust them; and that they require the constant aid of the green crops being consumed upon them, or of a consolidation produced by remaining a time in pasture, and the consequent result of a sward of grasses and roots to produce vegetable mould by subsequent decomposition. There is no certainty of any substance properly called a manure having proved hurtful in itself; even in the case of being neutral, or producing neither benefit nor detriment, the just inference may be, that the fault lies in the preparation of the land and of the substance itself; and these causes joined with the circumstances of application, may not afford an opportunity of yielding the influence that might be expected from their active combination. Frequent marling of land will not prove hurtful more than other applications, if guided by the prudent maxims of reason and experience.

A marl has been found in the West of England of a red shining clay colour, which has proved very injurious to heavy lands, and the use of it is now interdicted. In Norfolk marls are found, and are easy of access, and have produced very great and permanent results; it has been described of a hard, dry and slaty appearance, sometimes streaked with yellow, friable, and soon crumbling by exposure; other kinds are found of seemingly impure quality, and are equally useful. They are now applied in smaller quantities and more frequent, as large doses are found to form a retentive subsoil like paste. The clays of Norfolk contain a portion of calcareous earth, and are by many eminent cultivators preferred to marl, and many of the great improvements effected in that county are to be attributed to the raising and mixing that subsoil with the lighter and upper stratum. In other parts of the kingdom, clays are also preferred to marls after a long and extensive experience of both substances, but such clays are soft and loamy, and effervesce slightly with vinegar. The great difference of the quality in which all these substances are found, render any rule or general direction wholly beyond the question; a mineral acid will show the presence of calcareous matter, but can give no directions deduced from that circumstance either of the general quality of the substance as a fertilizer, or of the quantity that will be required to produce a result. The presence or quantity of calcareous matter is no certain criterion either of quality or effect, for marls that show little or none by effervescence are good manures, and marls of great difference in colour and in chemical composition have been dug from the same pit where they lay contiguous and almost mixed with each other, and have shown no discernible difference of effect in any of the crops when applied in equal quantities on the same soils. The fairest test would be a trial made of a certain quantity of any substance on a given space, and conducted under common circumstances and on tangible grounds, and divested of the vaunting reports which have seldom been verified, and have tended to throw a discredit on the publications of truth.

J. D.

THE HISTORY OF THE HORSE— THE VARIOUS BREEDS—AND THE SUPPOSED HEREDITARY PREDISPOSITION.

BY MR. G. BAKER, REIGATE.

(From the Veterinarian.)

The value of the horse has been acknowledged from the remotest antiquity; and in tracing his history and utility, I am induced to refer to the inspired volume, because it is the oldest record extant. The sublime description of the horse in the 39th chapter of the book of Job must be known to every reader; and the writer of that book is supposed to have been coeval with Moses, and consequently many centuries prior to Homer, who was contemporary with Elijah.

The proximity of the land of Uz to Arabia may have suggested the description; and the Arabians so passionately admire this noble animal, that they have exhausted all the wealth of their fine language and rich imagination in descriptions of his beauty, spirit, and pride.

Thus Autar:—"Shedad's mare was called Jerivet, whose like was unknown. Kings negotiated with him for her, but he would not part with her. 'Seek not to purchase my mare,' he cried, 'for Jerivet is not to be bought or borrowed. I am a strong castle on her back, and in her bound are glory and greatness. I would not part with her were strings of camels to come to me, with their drivers following them. She flies with the wind, without wings, and tears up the waste and the desert. I will keep her for the day of calamities, and she shall rescue me when the battle-dust rises.'" There are many touches in a similar spirit in the history of the horse, Dalies, which was the occasion of a war among the Arab tribes. At a great feast, when the conversation turned upon celebrated horses, one said of Dalies, "He startles every one that looks at him; he is the antidote of grief to every one that beholds him, and he is a strong tower to every one that mounts him. When a night of dust sheds its obscurity, you may see his hoofs like a firebrand."

The Divine command to the Hebrews not to multiply horses, recorded in Deuteronomy, xvii. 19, has been a subject of much research and controversy with biblical critics. Michaelis, a learned orientalist and biblical critic of the last century, in his interpretations of the law of Moses, &c. gives much curious and valuable information on the subject. The divine command to Joshua to "hough the horses of the Canaanites," chapter xi, was the consequence of the above injunction. We find David also acting upon a similar occasion in the same manner. To hough a horse (the word is of Saxon derivation) is to hamstring it, or cut its thigh-sinew. Michaelis, who has devoted an article to this subject, and to whom we acknowledge much obligation for various illustrative information about horses, observes, that many expositors, from ignorance of military affairs and of the veterinary art, suppose the command in Joshua xi. to mean, not that the horses should be killed, but merely lamed in the hind legs, and then let go. But a horse thus severely injured would fall instantly back, and writhe about miserably until he died. The hamstringing can be done in an instant, and the animals generally bleed to death, or, should they survive, the wound never

heals, so that even if the enemy recovered them alive they were ultimately obliged to destroy them. He adds, it were inconsistent with the humanity of the law-giver to lame the horses without putting them to death: the permanent laming of a horse that would still live would have been extreme cruelty, for, being wholly useless, no one would care for it, or supply it with food.

The practice of hamstringing was not confined to the Hebrews: we find the Romans adopted the same course with the elephants of their enemies, having no desire for the assistance of such dangerous auxiliaries.

I believe the practice of hamstringing the bull is sometimes resorted to in the Spanish bull-fights.

The Israelites employed asses instead of horses for all the purposes of agriculture, &c. Christ entered Jerusalem on an ass, possibly in indirect obedience to the command; for he came not to abrogate the law of Moses, but to spiritualize and fulfil it.

In the 10th Commandment the Hebrews were enjoined not to covet the ox or the ass of their neighbours: if these neighbours had possessed a valuable horse, it would have been much more desirable.

A direct allusion to the absence of cavalry as a cause for a more implicit trust in the power of Jehovah, is frequent in the pages of the Old Testament.

In chapter i. of the 2d book of Chronicles, we find Solomon importing horses from Egypt, not only for his own use, but for the kings of the Hittites and the kings of Syria. There have not been wanting commentators who endeavour to prove that Solomon not only traded in horses, but profited by the supineness of the Egyptians, and their objections to the hazard of exportation by maritime commerce, combined with the facilities of his own dominions to secure a monopoly, while he increased the safety of his own territories by an effective body of cavalry.

It is interesting to observe the price given by Solomon's factors in the wholesale purchase of horses and chariots: each horse was 150 shekels, which, according to the lower or higher value of the shekel (2s. 3d. or 2s. 6d.), would be from 17l. 2s. to 18l. 5s., while the chariots at 600 shekels would be from 68l. 9s. to 75l. It will be observed that the latter sum is four times that of the former, which gives some probability to the opinion, that in this, as in other instances, the word *mercubah*, rendered chariot, denotes the horses belonging to a chariot; and, consequently, as it was then customary to yoke four horses to a chariot, the price of a set of chariot horses quadrupled that of a single horse. The Septuagint, however, understands a chariot to have been intended, and, upon the whole, it was most likely. Michaelis says the fixing of a price had the look of a monopoly, and indicates, besides, that horsemanship was in its infancy; for whenever people have sufficient knowledge of horses, with all their combinations of faults and excellencies, to judge of them as amateurs, one may be worth ten times as much as another, particularly in a king's stable.

In the prophecy of Isaiah (ch. v. ver. 28) of the invasion of Judea by the Babylonians, it is said, "their horses' hoofs shall be counted as flint;" and it is necessary to observe that this people were noted for their power in horses and chariots.

Xenophon, in the 2d book of the *Cyropædia*, represents Cyascares as stating to Cyrus the force

which the allies opposed to him might bring into the field. The number of the Babylonians was set down at 20,000 horse, and 200 chariots, double the number of any other power of Western Asia.

The allusion to the hardness of the horse's hoofs is conjectured to arise from the fact, that the ancients did not shoe their horses by nailing iron plates to the foot. They had, indeed, shoes of leather, gold, and silver; but these enclosed the whole hoof, and were bound or tied on, being used very rarely, and only on particular occasions. Hence the hardness of the hoofs was a very important consideration, and Xenophon lays much stress on this point, observing, that "the good hoof is hard and hollow, and, when struck on the ground sounds like a cymbal." He also suggests means by which the hoofs may be hardened. The necessity of such hard hoofs in war-horses did not escape Homer, who continually applies to them the epithet brazen-hoofed.

The fable of the centaur Chiron, the tutor of Esculapius and Achilles, is conjectured to have originated in the Thessalians having acquired the art of the manege from the Egyptians, who were, we know, acquainted with the value of the horse for riding and driving, first, from the ancient sculptures, in which both are represented; and, secondly, by Joseph's bartering the hoarded corn for horses and asses; and Miriam, in chanting the deliverance of Israel, celebrating the overthrow of both horse and rider.

The poetry of Homer abounds in allusions to steeds and chariots, which, with beauty and armour, constituted the most attractive portions of the spoils taken in battle. The coursers of Rhesus, fleet as the wind and white as the driven snow, were an inestimable prize to Thidides; and it was the hope of obtaining the immortal-bred steeds of Achilles that urged Dolon to the adventure that cost him his life. One of this "heavenly race" was subsequently endowed with the gift of speech and prophecy; but like Cassandra, raised his voice in vain.

The military strength of Greece did not consist in her cavalry, which was composed only of men possessed of estates, and able to furnish horses at their own charge.

The practice of human and veterinary surgery appear at this time to have been exercised by the same person. Hippocrates, the most celebrated Greek physician, and father of medical science, practised indiscriminately on the horse and his rider, (see La Fosse's *Dict. d'Hippiatrique*); and in addition to his medical works, he has written a treatise on the curative treatment of horses. Xenophon has also a treatise on equitation (*De re Equestri*), and an interesting description of the wild ass of the east.

The well-known anecdote of Alexander taming Bucephalus enables us to deduce three conclusions: that Thessaly still maintained its reputation for horses — that Macedon was far behind in the equestrian art — and that horses were of great value, as the price demanded for Bucephalus by Philonicus was no less than thirteen talents, or 2,518l. 15s. sterling.

When Darius advanced to meet Alexander, there were 400 led horses for the use of the king, exclusive of the cavalry, 10,000 of which body were slain in the battle of the Granicus.

At the foundation of Rome, Romulus chose 300 young men of the noblest families to serve on horseback; but, after the institution of the census by Servius Tullus, all persons who were worth

400 sesteritia (3,125), and possessed an unblemished character, had the honour of being admitted into the order of Equities. On being enrolled, a horse and gold ring were given to each, and he was obliged to appear on horseback whenever the state had occasion for his services. This constitution of cavalry continued until the time of Marius: after that period the military affairs (with which under the domain of ancient Rome every thing concerning equitation is inseparably connected), were remodelled. The knights preferred the enjoyment of ease and affluence at home to the dangers and fatigues of war abroad; their places in the army, therefore, were filled by foreign horse, and the title became a mere honorary appendage, unconnected with military duty.

A legion consisted of 3000 infantry, as at first fixed by Romulus; it was afterwards increased to 6000; but the common number was from 4000 to 5000. The Roman cavalry, in battle, were posted on the wings, or two extremities of the enemy, and fought sometimes on foot and sometimes on horseback, as the occasion required. I need not remind the classic reader of the description of the war horse in the *Æneid*, second only to that of Job. The line

"Rings to the solid hoof that wears the ground,"

proves by analogy that the practice of metallic shoeing was not yet established. This was first practised during the dark ages, when the classic term "*veterinarius*," employed by the writers of the Augustan age, became changed to that of "*farrier*," derived from the metal with which the horses were shod.

The Romans delighted in public games: they formed a part of what Bulwer aptly calls the graceful superstitions of paganism; and when, as in the chariot races, they were divested of the sacrifice of animal life, must have been alike exciting and picturesque.

The chariots were named *Bigæ*, *Quadrigæ*, &c., from the number of horses yoked to them: these were always arranged abreast, however numerous; and Suetonius relates, that at the Olympic games, Nero made use of a decemjugis, or chariot drawn by ten horses thus yoked.

Caligula paid divine honours to his horse, and fed him from vessels of gold in a manger of ivory.

The allusions to the horse, and subjects connected with him, become now so numerous in the Latin classics, that we will pass on to an author who has embodied in his writings the plith and spirit of their united productions; namely, Vegetius, a Byzantine nobleman, who flourished towards the close of the fourth century, in the reign of Valentinian II. His works were a sealed book during the long night of Gothic darkness; but on the revival of learning by Francis I., who commanded the translation of the Constantine collection, they were translated into Latin, and thence into the modern languages of Europe. From them we may trace the first work on veterinary subjects published in England, by Blundeville, in the reign of Elizabeth, which was chiefly a compilation from ancient authors who had written on the subject.

The first mention of horses in England is by Julius Cæsar, who remarks that, on his first invasion, the Britons had great numbers well trained to warlike exercises. The Romans, probably, contributed little to improve the breed of horses, since no trace of amendment are to be found during so many ages. There is a tradition, that the Eng-

lish mares and stallions were so valued by the Saxons, that Athelstan prohibited their exportation except as presents.

Roger de Bellême, created Earl of Shrewsbury by William the Conqueror, is the first who is recorded to have made attempts towards the ameliorating our native breed. He introduced Spanish stallions into his estate at Powisland, in Wales; from which that part of the country was for ages after famed for a swift race of horses. Strength and swiftness were then more important than shape, as the form of the horse was entirely hid by the armour at that time in use. The number of horses in the time of Stephen is said to have amounted to 20,000.

In the reign of Henry VII. and VIII. more particular attention was paid to the important improvement of the breed of our horses. The regulations made, and the means employed, were in unison with those unenlightened times, and consisted in arbitrary directions and impolitic restraints, not calculated to advance the intended purpose. Magistrates were empowered at Michaelmas tide to scour the heaths and commons, and put to death all mares considered of insufficient size to bear good foals; and the prohibition of Athelstan to export horses was continued, in particular as regarded stallions.

In the reign of Elizabeth the whole kingdom could not supply 2000 horses to form our cavalry. It was, probably, in consequence of this deficiency that our importation of foreign stock took place, which gradually improved the native breed. In the reign of James, horse-racing became fashionable throughout England. It was a favourite diversion of the Stuarts, and much encouraged by them. Cromwell did not forget that necessary appendage, a stud of race horses. By instituting royal plates at the restoration, additional encouragement was given to horse-racing, and much emulation was promoted among breeders, with the judicious view of perfecting and extending a race of horses fit for the road, the chase, and for war—while an enlightened policy allowed free exportation. From this period to the middle of the last century the system of renovation from the different original foreign stocks has been occasionally adopted; the consequence has been a decided superiority over the parent stock from each country, and a peculiar breed of our own, of all denominations, of superior proportions, speed, power, and utility.

Having traced the horse to a period when it is well known to all, as circumstantially as can be expressed in so limited a space, in continuation of the subject I will, in a future number, offer some observations on the distinguishing characteristics of the different breeds of horses, foreign and domestic, and conclude with some practical observations on the hereditary dispositions to malformations, and the necessity of selecting such animals for breeding as come nearest to the standard of desired perfection.

(To be continued.)

NEW MODE OF DETECTING ADULTERATION IN FLOUR.—An ingenious and scientific gentleman in Paris, M. Sellier, who, it will be recollected, some time since pointed out the intimate connection existing between sound and electricity, having had his attention called to the subject of the adulteration of flour, by its admixture with the fecula

of potatoes, has been so fortunate, in some recent electrical experiments, as to hit on a means which, with but little practice, may be employed by any one for the purpose of detecting the presence of fecula in flour, and showing the actual extent to which the fraud has been carried. M. Sellier's process is this: he takes a plateau or board of a flat surface, over which has been laid a coating of common sealing-wax, and charging part of this surface with positive and part with negative electricity, by means of a Leyden jar, he throws on it, through a barber's puff or small bellows, a small quantity of flour, when, if the article has been mixed or adulterated, even to a fiftieth part, the flour is completely detached from the extraneous matter, and attracted by the negative electricity, and the fecula by the positive. The appearance described on the waxed board by the fecula is what is known among scientific individuals as the figures of Lichtenbergh. The difference is so great between flour and fecula, when examined either through a microscope or magnifying glass, the fecula presenting a variety of bright transparent particles, while the flour retains its dead opaque white appearance, that the most unpractised eye requires but a short space to distinguish the one from the other.

NATURAL HISTORY OF BRITISH WOOL.

Wool has ever been the most pre-eminent of our staple productions. In the early ages of our history, it was one of the principal objects of commerce, and various kings took great interest in it as a valuable article for increasing the revenue. At this time the English were shepherds or wool-merchants, and sent this commodity chiefly to Italy and the Netherlands, where it was manufactured into cloth, and then returned to Great Britain; but this system of traffic proved very disadvantageous, and our English Justinian, Edward III. prohibited the exportation of it, invited, and encouraged the Flemings, who were persecuted in their own country, to settle here, granting them the free exercise of their religion, and many peculiar rights and privileges in return for the benefit derived from the introduction of the weaving branch. It must not be supposed that the manufacture of cloths was first actually brought into this country by the fugitive natives of Brabant and the Netherlands. Mr. Luccock, in his valuable treatise on wool, says "that the Romans not only taught the rude subjects the art of weaving, but succeeded so far as to induce them to exchange the skins in which they had hitherto been clothed for the more comfortable attire of their conquerors."

Winchester was the first place that possessed a manufactory, and hence we may reasonably conclude that through the first nine hundred years of the Christian era, wool in England was not entirely neglected. About the year 925 a fleece was valued at two-fifths of the whole sheep, the value of sheep continuing the same through several centuries; but in 1135 it declined fifty per cent., whilst wool at the same time greatly increased in price. The number of sheep in the kingdom was very inconsiderable before the time of Edgar, on account of the numerous herds of wolves which retarded their increase; but the measures adopted by that prince to destroy these animals, which are the natural enemies of sheep, manifested a degree of solicitude for the preservation of the flocks, which could scarcely be expected at a period so early, and were admirably adapted to promote that attention to them which contributed to their improvement. It appears that the bettering of the fleece did not keep pace with

the inclination of the people for fine clothes. In the reign of Henry II. Spanish wool, on account of its superior excellence, was imported and manufactured in this kingdom, but the policy of the age did not long permit it. The Mayor of London was ordered to burn every piece of cloth made of it. Yet again this tended to destroy the commercial spirit which began to manifest itself, and to throw the best materials into the hands of foreigners. About 1240 the importation of fine cloths into England, began to be encouraged; although the effects upon the fleeces of the country, and upon the interest of the farmers, must have been more pernicious than the manufacture of Spanish wool could possibly have been, had not the restless spirit of commerce counteracted the evil tendency; and carried out the surplus of wool, which it was calculated to create. The surplus of wool continued constantly to increase from the time of Henry II. down to that of Edward III. and exportation as regularly took it off the hands of the growers; accordingly we find in the southern parts of the island, where the manufacture was most attended to and from which the largest quantity was exported, that the flocks were in the best condition, and the quality of the staple most desirable.

Soon after this the importation of foreign cloth was prohibited, and in 1647, Parliament interdicted the exportation of wool,—a law which was finally established soon after the Restoration of 1660. English woollen cloths have now become noted throughout the markets of the globe for their texture, substance and durability. Still it is requisite to blend a foreign kind of wool with the English for furnishing the superfine cloths. It might be asked why does not England introduce that breed of sheep from abroad, whose fleece might supersede the necessity of importation? For these reasons—the British farmer has another object in view, exclusive of the demand for the fleece. Our nation consumes more animal food than most others. In hot climates, individuals would fall victims to the enjoyment of that which is here only moderation; and in cold countries, the inhabitants are too poor to obtain it; our farmers consequently prefer that species of sheep which is best adapted for the butcher. In Spain the Merino sheep are only valuable for their wool, they stand high on their legs, with large heads and long necks, contracted chests, and are sharp on the shoulders—narrow across the loins, having the skin remarkably thin, soft, and loose. The fleece in fineness and flexibility is probably superior to any other breed in the world; they have the appearance of being buried in wool; the length of the staple is from two to three inches. The number of these sheep throughout Spain has been estimated at about five millions, and are divided into two sorts, Trashumantes, and Estantes,—not that they differ in species, but the flocks of the former travel, whilst the latter are stationary. The Merino flocks chiefly belong to the Grandees, or societies of Monks, and one of the most noted is that belonging to the family of Count del Campo Alango, and from which the breed reared by his Majesty has descended. This flock is said to consist of at least 60,000, having the largest carcasses, and the heaviest fleeces, although the wool is not esteemed the finest. The race of the Escorial, is reckoned the finest wool of all.

We are happy to observe that at length every encouragement is given for the propagation of the crossed Spanish breed, which promises in a short time to make us independent of our neighbours for the article of wool; and make a market on the continent from our superior manufacture of cloth. The growth of wool is completed in one year, at the ex-

piration of which it spontaneously decays, and is naturally renewed. Different degrees of thickness prevail in various parts of the sheep, the wool being closer at the extremities than the roots; and that part which grows during the winter is of a much finer quality than that produced in the summer.

When first shorn wool is termed a fleece, and every fleece is usually divided into three kinds, viz, the prime or mother wool, which is taken from the neck and back; seconds, or that obtained from the tails and legs; thirds or that obtained from the breast. This general classification of wool corresponds with the Spanish methods of sorting which are, *Refinos*, *Finos*, *Terceros*; but there are some wool staplers, who distinguish nine different sorts. The following are the principal objects of attention in the present state of our woollen manufactures.

First, the length of the staple—for this regulates the various fabrics to which the fleece is destined. Thus in carding wool, a short pile and a disposition to assume a crumpled or spring-like shape is an object of prime importance. This shiveling quality Mr. Luccock observes, cannot prevail in too high a degree if it be to make cloths requiring a close and smooth surface. Cloth and woollen goods are made from wool possessing this property, namely felting—the short wool is carded, spun, and woven, and then put into the fulling mill, when the process of felting takes place; the stroke of the mill makes the fibres cohere, the piece subjected to this operation contracts in length and breadth, and its texture becomes more compact and uniform. This process is essential to the beauty and strength of woollen cloths; but for cloths where a long and even nap is required, such as stuffs and worsted goods, blankets, &c., too large a proportion of this curling property would be detrimental, consequently a long pile or staple will be preferable, which is deprived of this felting quality.

This is done by passing the wool through iron combs, which takes away the laminæ or feathery part, and approximates its nature more nearly to that of silk or cotton.

Secondly, pliability of wool is another very important quality.

Thirdly, a soft pile is necessary in a good fleece, and in this respect the Shetland wool is the best, its softness depends principally on the nature of the soil on which sheep are fed; those sheep which pasture on chalk districts, or light calcareous soil, produce hard wool, whilst those fed on rich argillaceous soils are distinguished by the softness of their wool.

Fourthly, the specific gravity, or relative weight of the pile.

Fifthly, the smell of wool is not much regarded, provided that no disagreeable odours are emitted; the wool must be pure, as this is necessary for bright colours.

Sixthly, the last property is trueness of hair, or a uniform regularity of pile, in which no coarse or shaggy hairs are perceptible.

There are various modes of classifying wool bearing animals, as long horned, short horned, and sheep without horns, but for the purposes of manufacture, the quality of the wool is obviously the best criterion. Among the longer ranges of long-woolled sheep, the first to be noticed, and the most northern, is situated near to the Tees, a river separating the Bishopric of Durham from the county of York. The second called the Lincoln district, comprehending the south eastern point of Yorkshire, nearly all Lincolnshire, and the Fen Lands of Huntingdon, Cambridge and Norfolk.

This kind of wool is found on sheep frequenting

the smaller marshes of Essex and Kent, which surround the inlets of the sea, but is much more abundant in those of Romney and Guilford. We meet with it in the counties of Dorset, Devon, and Cornwall upon the Cotswold Hills, in some detached parts of Lancashire, Oxford, Bedford, and Stafford, through the whole of Leicester, Rutland, Northampton, and Huntingdon, and along the banks of the larger rivers. It is remarkable that the short wools of the kingdom do not so distinctly range themselves in districts, as those of a longer staple, but fill up the whole space. Besides that which has been noticed as the pasture of the heavier breed of sheep, there are a few remarks which may be appropriately made here; wool of which hats are made is neither spun nor woven, but locks of it being thoroughly intermixed and compressed in warm water, cohere and form a solid tenacious substance. The art of producing from the fleece a warm clothing, was never lost, even during the days of the darkest ignorance. Luccock remarks that spinning and weaving were in use fifteen hundred years before the era of the common reckoning, and whilst the manufacture of cloth was confined to the houses of the grower, and the business of it transacted by his domestics, there was less room for the stimulation and exercise of genius than in after ages; yet in the simplest days of Greece, it was not deemed an employment unsuitable to palaces, nor did a princess degrade her dignity by superintending the labours of the loom, the distaff, and the vat. It was in such occupations, that she contended for the prize of fame, and after with her own hand drew the lengthened thread, or conducted it through the dividing web, happy to form a more splendid, firmer, or richer garment than her rival. By such innocent competitions, they produced the most salutary effects upon the workmanship of each other, the classes immediately below them, and upon the fleeces of their country; doubtless they were at first compelled to exert their ingenuity upon imperfect materials, to attempt the production of soft and attenuated threads, like those which they saw in the linens of Egypt, from coarse and elastic ones, and to give the beautiful colouring of the several flowers, to dark and dingy fleeces. Under such disadvantages, and excited by an almost unbounded spirit of emulation to display their taste and gratify the vanity of their masters, the golden fleece of Colchis must have appeared to them a treasure, sufficiently valuable to become in part the object of a voyage full of dangers, and to be celebrated in the songs of Orpheus.

REMARKS ON THE ROADS IN FRANCE.--

No hedges, no divided fields, no cattle grazing; women doing farm labour; horses talked to, and reasoned with, instead of being beaten. If a peasant wants to get on a little faster, he descends from his *roulage*, and runs on before the horse, who immediately sets off after him. No comfortable-looking houses, to which you may suppose Mr. Jenkins, Mr. Smith, or Mr. Higginbotham to have retired, after a life spent in business. No nice little gardens, with monthly roses, bee-hives, cabbages, onion-beds, in front of the poor man's cottage; no wall-flowers near the door, nor tuft of house-leek over it; no little patches of sweet-william, nasturtium, strawberry plants, currant and gooseberry bushes. Thinks I to myself, "You may grumble at home, my boys: but you would be sorry to change with your own class in France"—that is, as far as I saw of it.—*Journal of Barnes, the Pantaloon, in Bentley's Miscellany.*

WEST SUSSEX AGRICULTURAL ASSOCIATION.

From the above subject we turn to another of an extremely opposite character, and calculated to engender feelings of a very different kind, and in which the high and mighty in the land are found mingling with the lowly and humble, in which those whose rank in society brings them in immediate contact with royalty, and notes them as the first in the land, exalt themselves far above the honours which station can confer, by promoting the mental and physical happiness of the poor and him that hath none to help him, of the man whose lot it is to earn his daily bread by the sweat of his brow. Whether it is that when the mind is brought back from the plodding daily pursuit of business, which leaves little time for the exercise of the finer feelings, the mind becomes more susceptible, we know not, but this we can safely assert, that never have we found our feelings so powerfully operated upon as when witnessing the proceedings at the meeting of the West Sussex Agricultural Society, for the distribution of prizes to meritorious agricultural labourers, on Friday last.

This society has been established five years, and has, during that period, distributed nearly 1,000*l.* His Grace the Duke of Richmond is president of the society, and labours earnestly to promote its prosperity. The best evidence of his zeal and exertion on its behalf, will be found in the fact that although detained in the House of Lords on the debate on the corn laws, which came on on Thursday night, and was protracted until past three o'clock on Friday morning, yet he travelled to Goodwood, upwards of sixty miles, and arrived precisely at one o'clock on Friday, the hour appointed, to take the chair at the meeting. This society is the first which admitted the labourers, successful candidates, to dine in the same room with the members. Upon this occasion the dinner took place in the Tennis Court, on the confines of the park; about 150 gentlemen sat down to dinner, and nearly 100 labourers, to whom the prizes were to be given, at tables at the other end of the room. His grace was supported by the Lord Bishop of Chichester, Archdeacon Wilberforce, C. S. Dickens, H. Hollist, Esq., a large body of the clergy in the counties of Sussex and Hants, several visitors from a distance, and a large number of farmers. The Duke of Richmond occupied the president's chair, and the vice chair was filled by a venerable old labourer, 80 years of age. Animated with the same estimable and benevolent spirit which actuates the noble duke, his eldest son, the Earl of March, took his seat at the labourers' table, and on the few occasions when he was called upon to address the meeting, expressed himself in terms which called forth the warmest marks of approbation from the meeting. As soon as the cloth was removed, the president rose, and having, in very appropriate language, adverted to the recent attack upon the life of her Majesty Queen Victoria, read an address for the approval of the meeting, which he proposed should be presented to her, and which was unanimously approved and adopted. The other useful loyal toasts having been

given, the healths of the Lord Bishop of Chichester, the Archdeacon Wilberforce, &c., having been drunk and responded to, the distribution of the prizes was commenced. The first prize was the gift of the Bishop—a bible and common-prayer book, in large type, adapted for old persons, handsomely bound: it had been awarded to the old man, who occupied the vice-president's chair, and was presented to him by his Lordship with an appropriate address, as were also the other prizes of the like kind. These prizes were in addition to any others awarded to the candidates by the society.

His Grace the Duke of Richmond then proceeded to present the prizes awarded to each of the successful candidates in sums of money from ten shillings to five pounds. The varied remarks made by his Grace to each individual, applicable to the peculiar circumstances of the case, and his local knowledge extending to every parish in the whole of West Sussex, attracted general observation. The instances of long services, in one case amounting to 50 years, of large families brought up without any parochial relief, and of money saved by some of the successful candidates, was surprising, and tells well for the character of both master and man. Nor was the conduct of the females less deserving: in one instance, a widow, having maintained three children without parochial assistance. But the prizes which, above all others, were most calculated to call into action the best feelings of our nature, and the recital of which deeply moved many in the room, were those for both males and females, married and single, who, according to the conditions in each case, after providing for themselves, had "afforded the most material aid to their parents or relatives." Here was seen, in the conduct of the uneducated peasant, the genuine working of the affections of the heart. Here were displayed acts, which, upon reflection, must have humbled the haughty, had any such been present, and, we are persuaded, did elevate the character of the poor working-man in the minds of the lookers-on. Married men, having families, making allowance to, and even supporting, their parents out of their small earnings, brother assisting brother, and lads of 18 and 19 giving up the *whole of their earnings* for the support of a father or a mother, and the rest of the family. Encouragement should be given to good conduct of every description, but in no way will a more decided and marked amendment, be effected in the general conduct, than by the cultivation of the kindly feelings of our nature. The lot of the labourer is one which needs the aid of his superiors in worldly matters; he has, as it were from his very outset in life, a barrier set round him, which he cannot pass; subject to privations even in the best of times, he occasionally experiences hardships, which renders it difficult to resist temptations to transgress those laws which he is told by the wicked and designing, are made to benefit others and to injure him. Relying upon the labour of his hands, if he fail to obtain it, is it surprising that he should be driven sometimes to acts of impropriety? A living writer says:—

"A man willing to work and unable to find work, is perhaps the saddest sight that fortune's inequalities ex-

hibit under the sun. Burns expresses feelingly what thoughts it gave him—a poor man seeking work—seeking leave to toil, that he might be fed and sheltered; that he might be put on a footing with the fourfooted workers of the planet which is his! There is not a horse willing to work but can get food and shelter in requital, a thing this twofooted worker has to seek for, to solicit occasionally in vain; he is nobody's twofooted worker; he is not even anybody's slave."

Let the high and mighty recollect that this is frequently the condition of the British labourer. Let them learn from the statements above, that he has a heart cast in the same mould, and endowed with the same qualities with themselves, and that it is his difficulties and unfortunate position which drive him to acts which, under other circumstances, he would abhor. Let them reflect that he asks only "work," and they will, we hope, be awakened to the reflection, that the goods which they enjoy are held in a great measure in *trust*, and that it is only required of them to exercise that trust in an equitable manner, not in any way disregarding their *own* interest. We earnestly entreat those who have not witnessed a meeting of the kind, to visit the meeting of the West Sussex Society, as we feel persuaded that a conviction of the benefits resulting to all parties from the establishment of such institutions, will be the result. In order to afford information to persons who may be desirous of introducing the system pursued by this Society, we subjoin a detailed account of the proceedings. —*Mark Lane Express*.

The fifth general meeting of this excellent Association, convened for the distribution of premiums to the successful agricultural and domestic labourers, for skill, honesty, industry, and general good conduct was held at Goodwood on Friday, June 12, when there was a large muster of the nobility, gentry, and clergy, to do honour to the occasion, and to testify by their presence and countenance their approbation of the meritorious conduct of those who had so deservedly been awarded premiums. Fortunately the day was fine, but cloudy, a circumstance of some advantage to the shearers. During the forenoon a great number of carriages, with ladies and visitors, arrived to witness the interesting scene exhibited in the competition for the sheep-shearing prizes. This excellent association, one of the first established in Sussex, has continued to increase in importance and utility, and has been productive of much benefit throughout the county, both by precept and example. The business of the day commenced in the park by the sheep-shearers being allocated in their different stations, each having six sheep to shear. There were as many as thirty candidates entered to compete for the premiums offered: the certificates of one, however, were informal. The following were the awards made, with the number of the pen in which the candidate was placed:—

- £3. to William Pryer, jun., of Harting, No. 1.
- £2. to George Brown, of Wymering, No. 11.
- 30s. to John Martin, of Harting, No. 14.
- 30s. to William Quennell, Bexgrove, No. 9.
- 15s. to William Glaysher, Chithurst, No. 26.

About half-past two, dinner having been announced, the members, company, and successful candidates, adjourned to the Tennis Court, Waterbeach, where an excellent dinner had been provided by Mr. R. Wood, to whom this portion of the business of the day was very judiciously entrusted. His Grace the Duke of Richmond, K.G., President of the Association, accompanied by the Lord Bishop

of the Diocese, led the way, preceded by the band, and were followed by a long train of gentlemen.

Two long tables were laid the whole length of the Tennis Court, but these being found insufficient to accommodate the very numerous company on this occasion, a third table was added down the centre. There could not have been less than 300 persons present at dinner, besides whom numbers dropped in after the cloth was removed. The room, which was very tastefully decorated with laurels, flags, and emblematic devices, since the last meeting had been completely enclosed and glazed, and was therefore very comfortable and commodious in every respect.

The Duke of Richmond was supported on the right and left by the Bishop and Dean of Chichester, Archdeacons Webber, Wilberforce, and Hare, C. S. Dickens, Esq., H. Holliet, Esq., &c. In the Vice-President's chair, at the lower end of the room, was the venerable old man who was in the chair last year,—Thomas Gardener, of Appledram, aged 80,—the same to whom the handsome premium offered by the Lord Bishop of Chichester was awarded. Supporting this venerable octogenarian, and mingling with and assisting the labourers, were Lord March, Lord H. Lennox, Mr. C. Osborn, Mr. John Ide, and others. Among the company we also noticed the following clergymen and gentlemen:—the Revs. Messrs. H. E. Manning, H. Browne, W. Miller, E. Miller, H. Atkins, Rusbridger, W. Watkins, Thompson, C. Hutchinson, C. Marriott, H. Legge, T. S. Cogan, H. Cogan, W. Turner, T. Brown, Luxford, Wither Smelt, R. Millikin, S. Fairles, Buckner, S. Westbrook, R. Tredercroft, S. Douglas, J. W. Deacon, L. Johnson, E. Edele; Captains Stracey, Pilkington, R.N., Tucker, Harrison, R.N.; Doctors M'Carogher, and Forbes; Messrs. F. Smith, J. Napper, W. Wagner, C. Teedale, E. and W. Humphrey, J. B. Freeland, E. Freeland, C. Dorrien, B. Martin, G. Henty, R. Elliott, G. Peskett, Putland, Grantham, Cole, J. Sivewright, J. Elliott, H. Comper, sen., W. Dewey, sen., and jun., J. Price, W. Postlethwaite, W. Titchener, W. Gibbs, J. Hack, &c., &c.

On the removal of the cloth, grace having been said by the Lord Bishop, the Chairman rose to propose as the first toast, the health of "The Queen," prefacing it by the following remarks:—Circumstances had occurred within the last few days, which he should ill perform his duty as chairman of this meeting, did he not allude to; and before asking them to drink with becoming loyalty, to the health of her Majesty, he begged of this numerous and respectable meeting to join him in an address of congratulation, expressive of their horror and indignation at the diabolical attempt against her Majesty's life which had been so lately made. (*Cheers*.) He felt that there could be no more fit and proper occasion than the present for such an expression of feeling, when so large and numerous an assemblage were met together, including the Bishop and the Clergy, the Landowners, the Magistrates, the Farmers, the Labourers. He asked of this meeting then, if they agreed with him in his proposition, to give him permission to read to them the draft of an address to be signed by him as their chairman, and forwarded to her Majesty. His Grace then read the address, which expressed horror and indignation at the atrocious and treasonable attempt on her Majesty's life, and congratulation at her preservation from so great a danger. It further expressed deep concern that a being could be found in her Majesty's dominions, base enough to attempt so flagrant and wicked an act; and concluded by

offering an "earnest prayer to Almighty God that he would long preserve to us the blessings we enjoy under her Majesty's mild government, and continue to preserve to us all we hold dear." (*Loud applause and unanimous approbation.*) His Grace then went on to comment upon the coolness and bravery which her Majesty had displayed upon this occasion, proving herself not unworthy of the brave and illustrious stock from which she was descended, inasmuch as she had driven out the next evening in the same open carriage through the same thoroughfares, thereby testifying her confidence in the loyalty and affection of her people. His Grace concluded by proposing the health of "Her Majesty," hoping that she might long be spared to reign over the country with credit to herself, and advantage to her subjects, who owe her allegiance. (*Applause.*)

The healths of "His Royal Highness Prince Albert," and of "The Queen Dowager and the rest of the Royal Family," were then given from the chair, and drank with three times three.

The CHAIRMAN then called upon the company to drink to the health of "The Lord Bishop and Clergy of the Diocese of Chichester." The society which he had the honour to address had received a great deal of support and countenance from the Right Rev. Prelate, who, they were well aware, besides attending at their meetings, had given on this occasion some very handsome premiums to the labourers. Since his lordship had been at the head of the diocese, he had by his affability and courtesy endeared himself to all who knew him, and had exerted himself to the utmost to advance everything tending to promote the spiritual welfare and temporal well being of the labouring population of the county generally. For this they were all deeply grateful to him, and they looked up to his lordship with regard and respect. Of the resident and parochial clergy he need say little, for they were well known to those present—their neighbours and friends—and he was most happy to see so many of them present to-day. They all knew from every day's experience how consistently the clergy performed the duties of their sacred office, how diligently they ministered to the spiritual wants, and sought to advance the temporal welfare of their flocks, how patiently and assiduously they visited the cottages of the poor and the dwellings of the rich, ever ready to afford consolation in sickness or adversity, faithfully preaching the gospel, and more than this, abiding by its truths and following its precepts. He begged they would drink to the health of "The Bishop and Clergy of the Diocese" with three times three.—Drank with musical cheers.

The Bishop of CHICHESTER rose to return thanks on behalf of himself and the clergy. They were indeed highly honoured by the reception they had met. With respect to himself, he was all unworthy of the kind and honourable mention which their president had been pleased to make of his humble services. But it was most grateful and satisfactory to him to hear his brothers of the ministry so highly and respectfully spoken of. They would ever feel much pleasure in promoting the objects of the society in which they had been embodied, and would always be found ready to join in every institution having for its object the honour of God and the good of our fellow-creatures.—(*Applause.*) He believed the general wish of this society—as of the clergy—was to advance first the eternal interest, and afterwards the temporal interest of the people; piety and virtue would ever be found the best foundations of industry and skill, and where a store of heavenly knowledge had been acquired, there honesty, sobriety,

and good conduct would be sure to follow as its natural fruits.—(*Cheers.*)

The CHAIRMAN then rose and said, that having drank, in the manner he knew they would, the Bishop and the Clergy of the Diocese of Chichester, he had now to propose to them "The Clergy of the Diocese of Winchester," for they must be aware their society extended into the county of Hants. From all he had heard of the clergy of that diocese, they were every way worthy of the respect and esteem of the world, and they were honoured to-day with the presence of one of its most distinguished members, in the person of Mr. Archdeacon Wilberforce.—(*Applause.*) When I recal to your minds (said his Grace) the name which he bears (*applause*) that he is descended from one who, through a long life, exerted himself for the amelioration of his fellow-men, although of another colour (*applause*), by removing that blot upon our national character, that anomaly of a free and enlightened people, the upholding and countenancing of slavery, and when I tell you that the gentlemen who here represents the clergy of that diocese is known to inherit all the virtues of his father, that is enough for the farmers of Sussex to receive and drink his health with all due honour.—(*Loud applause.*)

Archdeacon WILBERFORCE rose to return thanks, and said: I really feel utterly unable to acknowledge the kindness with which this toast has been received. You must know, one and all, from experience, that there are some feelings too deep and too sacred in the mind to be expressed at will; and such is my case at the present moment. Your hearty, unanimous, and approving cheers have addressed themselves to the innermost feelings of my heart. My lords and gentlemen, my heart thanks you, though my words may not fully express it, for that remembering acknowledgment of him that is gone (*applause*), an honour which I deeply feel from such an assembly. I have never before been present at such a gathering as this, and I seem never thoroughly to have known before my native land—never to have known what it was that made our own England to differ in God's great mercy from every other land under the sun. I have to-day seen something of these sentiments, which have raised and ennobled the peasantry of our soil, and have lifted England to the preëminent rank in the scale of nations. Those feelings and that true conduct which has taught every man what it is to be a man, and so to fulfil his worldly duties as a man, I do believe from the bottom of my heart, and it is settled in the deepest of my convictions, that to that pure and reformed religion which we profess is England indebted for her greatness of soul—to that spirit of peace and goodwill, piety, and charity, which has taken deep root throughout the land. Upon the foundation of our excellent established church, our own civil and religious liberties are based; and so long as that is preserved, they are secure—so long as we build upon that enduring foundation, we, as a nation, shall endure and prosper.—(*Applause.*)

The CHAIRMAN then called upon the company to fill a bumper, and to drink with three British cheers prosperity to the labouring classes of the empire, more particularly to those worthy friends of theirs, who were their guests on the present occasion—"The successful candidates." He (the Chairman) had to congratulate the members on the manner in which the Society had increased in importance within the last few years. They might remember that the Society emanated originally from a farmer's meeting held at Chichester, at which he was in the chair. The first premium (said his Grace) was pro-

passed by Mr. Charles Osborn, who sits at the bottom of the room, and who I will always remind you was the originator of this very excellent institution. The farmers present at that time agreed with him on the propriety of establishing such an association, and the Society was formed. In 1837 there was only one competitor in class A. In 1839 there were twelve. Two years ago in class B five premiums amounting to 15*l.* were offered, and only four persons appeared to compete for them; at the present meeting, in the same class, there were nearly 50. He would repeat to those assembled around him, and remind them again and again of it, that there was no want of inclination on the part of the clergy, landowners, and occupiers, to find the necessary funds for rewarding merit, honesty, and industry. They all knew individually of the cases of merit, honesty, and industry in their parish, but the great advantage of this Society had been, that by its means they had been enabled to shew to the country at large how much of industry, merit, and frugality there was to be found among the lower classes, of whom they had just reason to be proud as labourers and domestics, and it was a pleasure to have to award them those rewards to which their good conduct had justly entitled them. This society was the first to set the example, which had since been generally followed, of asking the labourers to join them at the festive board: when they behaved well, they felt honoured and not disgraced by their attendance. Gentlemen, (continued the Chairman) I know, and you well know, the temptations to which every mortal is exposed, and the temptations to which the labouring classes are frequently exposed are of no ordinary nature. They are liable to all the diseases which human nature is heir to—and have often to contend with the pressure of want and the sorrows of adversity,—and if accident or sickness throws them out of employ it is satisfactory to find, as in many of the instances which will come before us to-day, that they have made some provision for the future by deposits in savings' banks, or subscription to benefit clubs. These are examples of what the people may do, if they have that active principle of religion and moral rectitude settled in their hearts; for triumphing over all the temptation to which they are exposed—they come to be respected by their neighbours and employers, and an honest, sober, and industrious labourer never need fear that he will want employment, so long as the feelings of the farmers of Sussex continue as they have been heretofore. I would say in conclusion to those labourers present, that if they feel any gratification at having been singled out and distinguished from their fellow labourers, not by favour or affection, but for their own honest merit, they have an efficient manner of showing their gratitude by setting a good example to their neighbours, and by instilling into the breasts of their children the principles of religion, which would guide and regulate their future conduct. I will say to you in conclusion, "Fear God, honour the Queen, live as brothers with your neighbours, and in Christian charity with all mankind."—(Applause.)

The Earl of MARCH rose and said—Gentlemen, I am requested by the labourers by whom I am surrounded, to return you their sincere and grateful thanks for the compliment you have paid them; and while I could have wished the task had fallen into hands better able to do justice to it, yet incompetent as I am to express all they feel on the occasion, I cannot refuse to perform so honourable an office as that which has been imposed upon me. I beg therefore to tender you again the expression of their

deepest and sincerest gratitude; and their earnest hope is, that they may long continue to merit and deserve the high eulogy you have been pleased to pass upon their conduct. The candidates were then severally called up to receive their premiums, each being presented, in addition to the amount he had gained, with a bordered card containing the particulars of the premium, to be hung up as a testimonial in his cottage. A number of ladies having entered the room to witness the interesting scene, were provided with seats behind the chairman.

Thomas Gardiner, the aged labourer who presided at the lower end of the room, having been called up to receive his premium, was thus addressed by the Bishop of CHICHESTER:—I am about to present to you a bible and prayer-book in large type; but before I give them to you, I would call your attention to a circumstance which I am sure you will highly prize, viz., that of the society having given to these prizes the first place of all the premiums—because they are founded upon the sure principle of Christian faith, which will bear you through this earthly pilgrimage, until you arrive at a better place. These books are given, I would have you to understand, not entirely because you have been a regular attendant at church during the whole of a long life—for you could not have expected any such reward, and therefore it proves that you loved your God and wished to set an example to your fellow-creatures, by showing them the fruits of piety and virtue which proceed in general from a regular attendance on the ministry. I have had, in the course of my life, to present many rewards for learning to young as well as to elderly men—but I can assure you I never presented one before which afforded me so much gratification and pleasure, as this tribute to a poor, honest, pious man. (Applause.)

The Bishop of Chichester's gift was (in addition to any other premiums,) to such agricultural labourers, above 50 years of age, who shall produce the best certificates of character, regard being had more especially to their regularity of attendance at church.—First, a Bible and Common Prayer Book of large type. Second, a Bible of large type. Third, a Prayer Book of large type. First prize to Thomas Gardiner, of the parish of Appledram, aged 80.—Second prize to Thomas Canner, of the parish of Oving, aged 73.—Third prize to Jeremiah Meal, of the parish of Sidlesham, aged 85.

The CHAIRMAN then proceeded with the distribution of the other premiums

CLASS A.—For labourers who have brought up the largest families respectably, with the smallest amount of parochial relief. First, 5*l.*; second, 4*l.*; third, 3*l.*; fourth, 2*l.*; fifth, 1*l.*—First prize to William Macklin, aged 59, of the parish of Earnley, employer H. Duke; has six children, eldest 32, youngest 11, one of whom is subject to fits and almost wholly dependent on him—the other five placed out at service—never received any parochial relief. William Macklin gained the second premium in 1838, and therefore could only now receive 1*l.* Wages, 12*s.* and rent.—Second prize, to John Ewens, aged 50, of the parish of St. Pancras, Chichester; employer J. P. Hayllar, for 20 years; has had twelve children, only three now alive. Candidate had the care of bringing up several others who died, one at eleven, another at seven; eldest child nineteen, and youngest seven, has had a great deal of sickness in his family, was drawn and served in the local militia from 1810 to 1815. In 1817 was drawn for the Sussex militia and paid 5*l.* 10*s.* for a substitute. Never received any parochial relief: Wages, 12*s.* to 15*s.*—3*l.* to Michael Cress, aged 64, parish of North Mundham, employer Mr. C. Gatehouse, 37 years on the same farm, has had thirteen children, eight died young in in-

fancy, eldest 38. Four children well placed out; the fifth, a girl, ill from her infancy, died at 17. The united parishes of Chichester allowed that girl 1s. 6d. per week; with that exception, no parochial relief. Wages, 12s.—21. to Joseph Stevens, 49, Westbourne; employer, Mr. W. H. Poate; 29 years on the same farm; wages, 37l. 4s. per annum, seven children, eldest 28, youngest 10, all out except the youngest, a girl, placed out at early ages, are remarkable for good conduct, relief 10l. 8s., none since 1821.—17. to John Boxall, 60, Slindon; employer, Mr. C. Mellish; on the same farm 23 years; wages, 12s.; has six children (boys) eldest 31, youngest 14, all placed out at eight or nine years of age. In consequence of great continued sickness in his family, and of his excellent character, the parish officers, unsolicited, gave him his house-rent for some time, and on the death of his wife he received 2l. 10s.

In addition to the above, the Sub-Committee recommended that the sum of 1l. be given to Daniel Beech, of Donnington; employer, Mr. C. Fogden; 50 years on the same farm; wages, formerly, 12s., now 6s., four children, two died; the eldest, Sarah, had two places in eleven years, when she married, and the other, Richard, two places in 26 years. No parochial relief, except 20s. once during illness.

CLASS B.—For labourers who have supported since the year 1829 the largest families respectably, with the smallest amount of parochial relief. First, 5l.; second, 4l.; third, 3l.; fourth, 2l.; fifth, 1l.—5l. to James Theates, 39, Westhampnett, employer, Duke of Richmond, wages, 14s., nine children, eldest 16, youngest 1½ years, has had to defray considerable expenses in consequence of the ill health of his wife, during the illness of a child for six weeks, and himself for four weeks; paid for medicine and attendance himself. Parochial relief in whole, 3l.—4l. to George French, 45, Racton, employer, C. Dixon, Esq., 24 years on the same farm, seven children, eldest 18, youngest 2 years, no parochial relief since 1829, and previously, in 1838, 2s. during illness.—3l. to Thomas Burchall, 45, Oving, employer Mr. H. Upton, 30 years in the same service, seven children, one died at 18 years, and another at 3. No parochial relief since 1829. Wages, 13s. [From the difficulty the Sub-committee experienced in awarding the remaining premiums in this class, and from the fact that 4l. in class A, was unappropriated, they recommended that the three individuals named below should each receive the sum of 2l.] 2l. to John Cussell, 36, Farcham, employer, Mr. C. Osborne, 30 years on the same farm; wages, 12s., six children; one died in consequence of an accident. His wife has had a severe illness, and he has paid at two different times 11l. 10s. for medical assistance. Previous to his present employ he paid 8l. per annum for his cottage, now reduced to 1s. per week. Never received any parochial relief.—2l. to Thomas Slaughtier, 42, Northmundham, employer Mr. Hollingdale, wages 12s., six children, eldest 11, youngest 1½ years, had previously to his marriage saved 15l. Never had any parochial relief.—2l. to Thomas Jacobs, 34, Racton, employer C. Dixon, Esq., has six children, eldest 10, youngest 2 years, wages 12s. Parochial relief, 20 gallons of flour in the year 1833.

CLASS C.—For widows who have brought up the largest families respectably, with the smallest amount of parochial relief. First, 4l.; second, 3l.; third, 2l.—2l. to Elizabeth Fleet, 40, Slindon, has been 12 years a widow, is exemplary in her conduct, bringing up her family respectably and in habits of industry, her cottage neat and clean, five children, eldest 17 years, youngest 12, earnings very uncertain, was allowed 5s. weekly for four months, which was reduced to 1s. 6d. till 1837, when it ceased.

CLASS D.—For widows who have supported since the year 1829 the largest families respectably, with the smallest amount of parochial relief. First, 4l.; second, 3l.; third, 2l.; fourth, 1l.—4l. to Harriet Pelham, 31, Boxgrove, has been a widow between three and four years, three children, eldest 9, youngest 3, born four months after her husband's death, earnings 4s. per week, her children still dependent on her, the two eldest being girls, paying 9d. per week rent, never received any parochial relief.—2l. to Charlotte Hill, Bosham, widow

seven years, two children, eldest 20, a girl in a sickly state of health from infancy, and always dependent on the mother, youngest 10. The candidate bears an excellent character in the parish for industry and unwearying efforts to maintain herself and two daughters. No parochial relief.—1l. to James Cobb, 50, Funtington, has been a widow upwards of 16 years, four children, one died at 14 and one at 18. Eliza, the youngest, was ill for three years. She conducts herself with great propriety, and turns her hand to any work, and is useful in the fields when wanted. From 1830 to 1835 received weekly assistance from the parish—first 5s., reduced by degrees to 1s.

CLASS E.—For labourers or widows whose daughters have been placed out at respectable service at an early age, and have remained in service with good characters, and whose families shall have made (by their own industry) the greatest improvement in their condition in life. First, 4l.; second, 3l.; third, 2l.; fourth, 1l.—4l. to James Wilde, 48, Singleton, employer Col. G. Wyndham, on one farm twenty-three years, eight children, four daughters, all placed out at service either at ten or eleven, having all excellent situations, which they have kept many years, eldest twenty-six, youngest ten, and single.—3l. to Sarah Sarby, widow, 58, Slindon, six daughters, eldest 35, youngest died at six months, five placed out at service at ages varying from 9 to 12, two are married, the other three have situations in good families.—2l. to Thomas King, 60, Westhampnett, employer Duke of Richmond, has worked on the Goodwood estate twenty years; ten children, four daughters placed out at ages from 10 to 13, one married, one died, two single, have situations seven, eight, and twelve years.—1l. to Edward Callo way, 58, Aldingbourne, employer Mr. J. Burnard, twenty-three years servitude, four daughters placed out at ages from 11 to 16. (Further particulars in class G.)

CLASS F.—For labourers or widows whose sons have obtained employment, or have been placed out at respectable service at an early age, and have remained in employment or service with good characters, and whose families shall have made, by their own industry, the greatest improvement in their condition in life. First, 4l.; second, 3l.; third, 2l.—4l. to George Hutchins, 68, Upwaltham, employer Mr. J. Heath, two services, one of 31 years and of 27; eleven children, seven sons, all began to work at from eight to nine years of age, and were all taken by one master, with whom they remained until they procured situations. (Further particulars in Class T.)—3l. to John White, 53, Mid Lavant, employer Mrs. Dorrien, worked for Mr. W. Shippin 14 years, Mrs. Dorrien eight years; eight children, six boys, eldest 31, youngest 11, placed out at ages from seven to eleven; they have excellent situations, which they have kept for eight, nine, and ten years; he supported a daughter during an illness of seven years, without assistance.—2l. to Thomas King, 60, Westhampnett, noticed in last class, six sons, one died in infancy, the rest placed out at ages from seven to nine; they have kept their situations for periods varying from five to thirteen years.

CLASS G.—For married labourers and widowers, who have been in employment or service the longest period, and who, in reference to their circumstances in life, shall have voluntarily afforded the most material aid or support to their aged parents, or have made provision for old age. First, 4l.; second, 3l.; third, 2l.; fourth, 1l.—4l. to Thomas Harding, 63, Earnley, employer Mr. H. Duke, three children, wages 10s., parochial relief 10s. in the whole; the candidate had in all ten children, supported a son for eleven months during illness, and has since entirely supported his grandchild; he has saved 15l., which is lent on note of hand at five per cent.—3l. to John Luffe, 61, South Hayling, employer C. Osborn, Esq.; in 1833 was run over and unable to work for six months, when he received 30s. from his parish; up to that time he had saved 14l., which was expended during his illness, since which he has saved 30l., till lately in Havant Savings' Bank, and now lent on interest; two services, one of eighteen and

one of nineteen.—21. to Edward Calloway, 58, Aldingbourne, noticed in Class E, for the last seven years has been in the habit of assisting his father and mother with at least 1s. weekly, and occasionally more, as he could afford it; he gives the old couple their Sunday's dinner at his own cottage.—11. to John Budd, 43, South Hayling, employer C. Osborn, Esq., seventeen years' servitude, five children, eldest 18, youngest 7, wages 13s.; within the last three years has saved 71., deposited in Fareham Savings' Bank, and pigs worth 31.

CLASS H.—For single labourers who have been in employment or service the longest period, and shall have voluntarily afforded the most material aid or support to their relatives. First, 41.; second, 31.; third, 21.; fourth, 11.—41. to Jacob Reed, 42, North Hayling, employer Mr. T. Rogers. Two services, one nineteen years and the other five. Wages from 31. to 91. in the house. Paid the expenses of his father's burial five years ago, and for the last ten years the rent of his mother's cottage and garden, 61. per annum. Is a member of a benefit society, and has obtained a premium for his garden.—21. to John Kent, 21, Eartham, employer Mrs. Huskisson, without change, wages 2s. to 9s. weekly. Belongs to a benefit society, and has supported his widowed mother for the last four years.—11. to William Horn, 43, Aldingbourne, employer Mrs. Huskisson, two services, one twenty-seven years and one eight years. Wages 10s., belongs to a benefit society, is very good to his mother, and pays the rent of her cottage.

CLASS I.—For single labourers who have been in employment or service the longest period, and shall have made the best provision for sickness or old age. First, 41.; second, 31.; third, 21.; fourth, 11.—41. to George Barber, 24, Westdean, employer, W. L. Woods, Esq., has had three services, but with increasing wages, from 2s. 6d. to 12s. per week, has 151. in money, a watch which cost 41. 4s., furniture worth 61. Member of a benefit society eight years, paid 11. at his brother's death for medical assistance, and has given his father 30s.—31. to William North, 44, North Hayling, employer, Mrs. Carpenter, twenty-four years servitude. Wages 10s., has 441. 9s. 4d. in Havant Savings Bank, and 181. lent at interest, in all 621. 9s. 4d.—21. to William Chatfield, Fareham, employer, Mr. C. Osborn, six years servitude. Wages, 12s., has 171. 11s. in Fareham Savings Bank, rents an allotment of a quarter of an acre, which is well cropped, and member of a benefit society.—11. to John Forrester, 49, Eartham, employer, Mrs. Huskisson, fifteen years servitude, has 261. in Chichester Savings Bank, and has been twenty-one years member of a benefit society.

CLASS K.—For single labourers under 20 years of age, who have been in employment or service the longest period, and shall have voluntarily afforded the most material aid or support to their relatives, or made the best provision for sickness or old age. First, 31.; second, 21.; third, 11.—31. to George Clarke, 19, South Hayling, employer, Mr. Hellyer, four years, wages, 3s. to 10s., has 151. 1s. 9d. in the Havant Savings Bank, and member of a benefit society.—21. to John Parvin, 18, Westdean, employer, Mr. J. Hipkin, seven years with Lord Selsey, but always on the same farm, wages, 2s. 6d. to 9s.; all his earnings are given to assist in keeping his mother and sister.—11. to James Birch, jun., 18, Warberton, employer, Mr. W. Halsted, nine years, wages 2s. to 8s., is a member of a benefit society, and by his wish and consent all his earnings are given to his father, and applied to the support of the family, consisting of seven besides himself.

CLASS L.—For female agricultural domestic servants who have been in service the longest period, and shall have voluntarily afforded the most material aid or support to their relatives. First, 41.; second, 31.; third, 21.; fourth, 11.—41. to Charlotte Phillips, 24, Upwarden, in the service of Mrs. C. Wyatt five years and a half, wages progressive, from 51. to 81., and during the time she has been in her present servitude she has allowed her parents 31. per annum, with exception only when suffering herself from a long illness, when for six weeks she was an inmate of the Chichester Infirmary;

they have received smaller sums from her at other times.

CLASS M.—For female agricultural domestic servants who have been in service the longest period, and shall have made the best provision for sickness or old age. First, 41.; second, 31.; third, 21.; fourth, 11.—41. to Hannah Pelling, 28, Birdston, in the service of Mr. Walter Calhoun, wages 81. per annum, has 171. in the Chichester Savings Bank, has also assisted her mother at different times during the whole of her servitude, ten years, with Mr. Calhoun.

CLASS N.—For female agricultural domestic servants under twenty years of age, who have been in service the longest period, and shall have voluntarily afforded the most material aid or support to their relatives, or made a provision for sickness or old age. First, 31.; second, 21.; third, 11.—31. to Hannah Young, 18, Oving, in the service of Miss Boniface four and a half years, wages progressive from 21. to 41. 10s., has 71. 10s. in Chichester Savings Bank. 21. to Ellen Ford, 17, Birdham, in the service of Mr. T. Sparkes four and a half years, board and part clothes, wages, first year to 31., has 21. 10s. now by her.

CLASS Q.—For shepherds of flock-masters having the care of not less than ten score of ewes, who have reared the greatest number of lambs with the least loss, regard being had to the circumstances both as to the farm and flock. First, 41.; second, 31.; third, 21.; fourth, 11.—41. to James Ford, Westdean, employer, Mr. James Hipkin. 225 ewes put to ram; 20 two-tooth, 105 four-tooth, 100 sixth-tooth; died during the year, 1; remaining alive, 224. 307 lambs dropped, 16 given away, 1 born dead, 6 died before weaning, 284 remaining alive at weaning, 4 barren ewes. Has lived twenty years on the same farm. 31. to Joseph Chalton, East Lavant, employer Mr. C. Duke. 510 ewes put to ram; 160 two-tooth, 165 four-tooth, 185 six-tooth; 9 died lambing, 5 in other parts of the year, 496 remaining alive at weaning, 614 lambs dropped, 54 given away, 24 born dead, 4 died before weaning, 532 alive at weaning, 25 ewes barren, 6 slips. 21. to Richard Burns, Westdean, employer Rev. L. V. Harcourt. 273 ewes put to ram; 81 two-tooth, 28 four-tooth, 164 six-tooth; 2 died lambing, 4 at other times, 267 remaining alive; 332 lambs dropped, 17 lent, 7 born dead, 13 died before weaning, 295 remaining, 15 barren ewes, 5 slips. 11. to William Mitchell, Eastbourne, employer Thomas Jenner. 500 ewes put to ram; 19 two-tooth, 31 four-tooth, 450 six-tooth; 8 died lambing, 4 during other times, 488 remaining alive, 598 lambs dropped, 9 born dead, 19 died before weaning, 570 remaining alive, 17 barren ewes, 2 slips.

CLASS R.—For shepherds of graziers having the care of not less than 100 forward ewes, who have been the most successful in lambing them with the least loss, regard being had to the circumstances both as to the farm and stock. First, 21.; second, 11.—21. to Edmund Mail, Sidlesham, employer Mr. James Hobgen. 183 six-tooth and full-mouthed ewes put to ram; 6 died in lambing (3 extreme cases, 3 debility), 2 at other parts of the year, 175 remaining alive, 10 sold at Chichester market April 22, 165 remaining, 206 lambs dropped, 4 born dead, 9 died before weaning, 193 alive on May 16 (date of certificate), 15 barren ewes, 1 slip. 11. to William Voller, Westbourne, employer G. Hipkin. 307 ewes put to ram; 20 two-tooth, 35 four-tooth, 60 six-tooth, 192 full-mouthed; 1 died lambing, 2 at other times, 304 remaining alive. 323 lambs dropped, 1 born dead, 4 given away, 8 dead before weaning, 310 remaining alive, 5 slips.

CLASS S.—SHEEP SHEARERS.—The award in this class is given above.

The CHAIRMAN, after awarding these premiums, made some remarks relative to the defeat of the West Sussex shearers in the recent match in the East, observing that it was no disgrace to have been beaten, seeing that it turned upon a question of taste as to the mode of shearing practised in the two divisions, which were essentially different. He should make enquiries before next year as to which was the

preferable mode of shearing, the old plan or the new. Their shearers had proved themselves to be excellent workmen to-day, and more than this, they were never rewarded for skill and industry, unless they produced certificates of good and moral character.

CLASS T.—For the labourer who, previously to the time of his marriage, had made the best provision for his future maintenance in life. First, 4*l.*; second, 3*l.*; third, 2*l.*—4*l.* to George Hutchins, Upwaltham, noticed in Class F.; present age, 63, at time of marriage, 32; was an in-door labourer at 10*l.* per annum; had 40*l.* in Petersfield Bank, a watch worth 3*l.* 10*s.*, furniture worth 14*l.*; in all at time of marriage, 57*l.* 10*s.* 3*l.* to Henry Oakley, Westhampnett; present age, 29, at time of marriage, 24; present wages, 12*s.*, at time of marriage, 10*s.*; had saved 10*l.* in money, a clock worth 2*l.*, watch 3*l.* 3*s.*, furniture worth 8*l.*; employer, Mr. Cogan; in all 23*l.* 3*s.* 2*l.* to William Cooper, Westbourne; present age, 35, at time of marriage, 30; was an in-door tenant at 3*s.* per week; had saved 25*l.*, of which 20*l.* were placed out at interest; employer, Mr. Scardewille.

CLASS U.—To the cottagers who shall have the greatest number of stalls of bees, on the 1st of May, 1840. First, 2*l.*; second, 1*l.* 10*s.*; third, 1*l.*; fourth, 10*s.*—2*l.* to James Keates, Westhampnett, who had on the 1st of May, eleven stalls of bees. 1*l.* 10*s.* to Stephen Stillwell, Upmarden, who had on the 1st of May, eight stalls of bees. 1*l.* to Samuel Hall, Eastmarden, who had on the 1st of May, six stalls of bees. 10*s.* to William Cress, Pagham, who had on the 1st of May, six stalls of bees.

Also a premium of 2*l.* for the best written account of the actual experience of the candidate, of the best method of treating and preserving bees through the winter, with the sort and quantity of food required for the daily support of a hive—the best method of securing the swarms at the time of swarming (stating the number of swarms produced by each hive), the average weight of wax and honey from a certain number of hives—the greatest weight of honey and wax from a single hive—the number of hives lost by natural death in a given number of hives. A premium of 1*l.* for the second best account, containing the same information; the gifts of Mr. J. Hack, and Mr. E. Wyatt.—2*l.* to Stephen Stillwell, Eastmarden; 1*l.* to James Keates, Westhampnett.

MR. JAMES HACK made some observations, recommending that these treatises should be published, and circulated by general gratuitous distribution among the labourers.

The CHAIRMAN said he had already anticipated this subject; and the Royal Agricultural Society of England were disposed to receive these papers on the treatment of bees, and if found worthy, to publish them in their *Quarterly Journal*. It was then open to this Society to order a certain number of copies to be struck off, while it was in type, to be given away to the successful candidates, and to the members of this Society generally.

The Bishop of CHICHESTER remarked that this was one of the most extraordinary things he had ever heard in the whole of his life, that a labourer should receive a premium for writing an essay on the management of bees, and that this essay should be thought worthy of being printed, in order to show other Societies what they were doing, and that other labourers might profit by the hints thus thrown out.

The Dean of CHICHESTER said, that he thought that a toast at the present moment would not be unacceptable to his Grace, as a little relief after the very interesting and onerous labours which he had gone through. The toast he had to propose was the health of "The Earl of March." (*Loud applause.*) He was quite sure that name would call forth enthusiastic applause after what he had witnessed when the name of his noble father had been mentioned,

and knowing the admirable services which the Duke of Richmond had rendered to the county. It was a beautiful spectacle to see a nobleman of the highest rank and station seated in the chair, and the vice-chair filled by a humble labourer. He believed the Earl of March would ever emulate the hereditary excellence of his ancestors, and be what his father had been before, a blessing and a benefactor to the country; and after the sample and specimen they had already had of his conduct, they would hereafter, through a long series of generations, have to hail and bless the name of Lennox. (*Cheers.*)

LORD MARSH, in a neat and appropriate speech, returned thanks.

The CHAIRMAN, in proposing "Prosperity to the other Agricultural Associations of the county," said he was glad to see so many springing up around them. Chichester was the first place to set the example, and there were now institutions at Petworth, Arundel, and Fittle, to all which he wished prosperity; and he would couple with them the healths of Mr. Putland and Mr. Grantham, who were their visitors to-day. He thought he ought to claim some little credit at their hands; for Mr. Grantham was one of the very few who had been able to wrest from him the premiums for South Down sheep, at the Smithfield Show. He must therefore be understood as not drinking prosperity to Mr. Grantham's flock, but only to himself. (*Laughter.*) He trusted, however, that East and West Sussex would never be rivals in any thing, except attempts to improve that stock of sheep which all were anxious to keep up.

MR. H. HOLLIST said, he was obliged for the compliment which had been paid to him and to others, and to the Society which he represented. He did not rise to return thanks for the Arundel Society, which was too well and extensively represented here, nor for Mr. Grantham or Mr. Putland, but for that "baby" institution, as it had been termed, the Petworth Society,—a society which, he hoped, would yet be productive of much real good. At their first meeting, held recently, they had distributed 116*l.* in premiums among 68 successful candidates; and it was no small source of pride to himself that labourers in his employ had carried off five prizes, amounting to sixteen guineas, and that three of the men had been with his father and himself 130 years. He thought that for what they had already done they deserved some credit; and he hoped this society would continue to extend its kind and fostering and parental affection to the "baby" institution until it was out of leading-strings.

MR. GRANTHAM returned thanks for the East Sussex Association, as did Mr. BISHOPP for Arundel, remarking that he should be happy to become a subscriber to the Petworth Association, as well as to this and the Arundel Association.

CLASS W.—To cottagers resident in the following districts, whose cottages and gardens, consisting of not more than half an acre, shall be kept and cultivated in the neatest manner, and the general appearance of whose crops, making due allowance for the natural quality of the soil and the size of the garden, shall be most satisfactory to the judges appointed to view them. No persons shall be eligible for the following premiums who have kept their daughters from domestic service after they have attained the age and strength for such employment.

DISTRICT 1.—To cottagers resident in the united parishes of the City of Chichester, 1*l.* 10*s.*, 1*l.* 5*s.*, 15*s.* 10*s.*—1*l.* 10*s.* to Edmund Collins, Subdeanry; 1*l.* 5*s.* to William Watts, Subdeanry; 15*s.* to James Parson, Subdeanry; 10*s.* to James Farr, Subdeanry.

DISTRICT 2.—To the same in the parishes of Selsey, Westwittering, Eastwittering, Earnley, Birdham, and

Itchenor, 11. 10s., 11. 5s., 15s., 10s.—11. 10s. to George Faith, Bordon; 11. 5s. to James Wells, Westwitting; 15s. to Joseph Voke, Westwitting; 10s. to Elizabeth Cate, Westwitting.

DISTRICT 3.—To the same in the parishes of Sidlesham, Huxton, Donnington, Appledram, North Mundham, and Merston, 11. 10s., 11. 5s., 15s., 10s.—11. 10s. to Henry Chaffer, Sidlesham; 11. 5s. to John Norton, Donnington; 15s. to James Clauter, Donnington; 10s. to Edmund Mail, Sidlesham.

DISTRICT 4.—To the same in the parishes of Thorney, Bosham, Westbourne, Chidham, and New Fishbourne, 11. 10s., 11. 5s., 15s., 10s.—11. 10s. to John Hother, Chidham; 11. 5s. to Joseph Tuckey, West Thorney; 15s. to George Lashley, Westbourne; 10s. to Thomas Medhurst, Newfishbourne, (too old to work).

DISTRICT 5.—To the same in the parishes of Funtington, Racton, Stoughton, Up-Marden, East-Marden, North-Marden, and Compton, 11. 10s., 11. 5s., 15s., 10s.—11. 10s. to Thomas Thornall, Stoughton; 11. 5s. to John Allen, Funtington; 15s. to Thomas Moore, Funtington; 10s. to John Wilkins, Funtington.

DISTRICT 6.—No competition.

DISTRICT 7.—To the same in the parishes of Eastdean, Upwalham, Earham, Slindon, Madehurst, and Graffham, 11. 10s., 11. 5s., 15s., 10s.—11. 10s. to Charles Herrington, Slindon; 11. 5s. to Charles Chatten, Graffham; 15s. to Joseph Kent, Eastham; 10s. to Daniel Dean, Slindon.

DISTRICT 8.—To the same in the parishes of West-Lampnett, Tangmere, Boxgrove, and Walberton, 11. 10s., 11. 5s., 15s., 10s.—11. 10s. to James Keates, West-Lampnett; 11. 5s. to John Triggs, West-Lampnett; 15s. to Will Oakley, West-Lampnett; 10s. to William Shipman, Boxgrove.

DISTRICT 9.—To the same in the parishes of Oving, Aldingbourne, Yapton, Climping, Whyke, and Eastergate, 11. 10s., 11. 5s., 15s., 10s., John Gale, Oving.

DISTRICT 10.—To the same in the parishes of Bersted, Felpham, Middleton, Binstead, Barnham, and Pagham, 11. 10s., 11. 5s., 15s., 10s.—11. 10s. to Edmund Stanford, Pagham; 11. 5s. to William Farr, South Bersted; 15s. to James Richards, South Bersted; 10s. to Jacob Pollington, South Bersted.

DISTRICT 11.—To the same in the parishes of Havant, Emsworth, South Hayling, North Hayling, and Bedhampton, 11. 10s., 11. 5s., 15s., 10s.—11. 10s. to John Bettsworth, South Hayling; 11. 5s. to Charles Biles, South Hayling; 15s. to William Tickner, Warblington; 10s. to Thomas Garnett, Warblington.

During one of the intervals of pause the Bishop of CHICHESTER availed himself of the opportunity to propose the health of the "Lord Lieutenant of the county." His friends at the lower end of the room would, he was sure, do ample justice to this toast, to their feelings and to his own, and mark how strongly they felt the advantage of having such a nobleman to preside over them. On every occasion where good morals, good feeling, and religion were concerned, his Grace was ever the first to come forward and set an example of what was praiseworthy and what was good; and his endeavours had been as successful as they were praiseworthy. Of all the situations in which his Grace had been, or might be placed, there was perhaps none which would cause him more pleasure, when he reflected on it at a future date, than his presidency over this excellent Institution. The time might come, when his Grace too might be called to place his head on a bed of sickness, and how consolatory would it then be to him to think that he had done his duty to the poor on all occasions, whether in providing at these meetings, or at the Board of Guardians, where he listened to every poor man's tale, and by his advice and influence made himself beloved and endeared to all. The fulfilment of such offices as these was more to his honour than any other, however splendid their accompaniments. He hoped that his Grace might long be spared to labour for their good. (*Applause.*) The labourers, in rising to drink the toast, made the room ring with their lusty cheers.

The CHAIRMAN said he felt obliged to the Right

Rev. Prelate for the kind mention which he had made of his name. He was not astonished at the manner in which they had received his health, for he had well known and long experienced the favours of the farmers of Sussex. The Lord Bishop had in his speech made some allusions to the task which he had to perform in reading the premiums, and had hoped therefore he might be spared the labour of returning thanks. It was no labour to him to assure them that he felt deeply grateful for all the favours he had received from them. He had only that morning left the House of Lords at four o'clock, and had had but one hour in bed; but he knew it to be his duty to attend here this day, and nothing but ill health or some very unavoidable circumstance would ever prevent him from presiding over them, so long as they honoured him by placing him in the chair. The influence and benefits of this society would, he hoped, extend not only over the county they loved, but over the kingdom at large—for they met on these occasions not to dispute upon politics and things of that sort, but to co-operate and be of service to their common country. He could only say that although, from a long and intimate acquaintance with most of those gentlemen whom he now saw around him, he found he was not so young as he was twenty years ago, he was not yet prepared to be put on the shelf on the present occasion. (*Cheers.*) It was a duty he owed to himself, to the members of this society, and to the labourers whom they were so happy to see among them, to attend and lend his influence on such occasions as these. He should have time enough to sleep to-morrow; he should therefore continue to read the premiums; and he hoped they would not again request him not to do his duty, for that would be to say he was unfit for it. He would conclude by drinking health, happiness, and prosperity to them and theirs. (*Applause.*)

The CHAIRMAN, in proposing "Success to the Chichester Infirmary," said he had taken the liberty, a short time since, of addressing circular letters to many in the neighbourhood, and of canvassing personally the farmers whom he met in the market. If the farmers generally were aware that an increase of funds was necessary to carry on this excellent establishment, he was sure the means would be immediately forthcoming. He had been very successful on the day when he canvassed, having obtained about 159*l.* in donations, and upwards of 70 guineas in annual subscriptions. But there were many whom he had not had an opportunity of seeing; and he thought there could not be a better occasion than the present for mentioning the circumstance. He had seen to-day one gentleman whom he had overlooked, who, he knew, if he had met him, would have subscribed; and perhaps there were also many others. He believed all would admit that the funds of that institution were very well managed, and were ready to acknowledge the blessings it conferred on the labouring population. There were very many diseases which could not be cured in the cottage of the labourer, and could only receive proper advice and medical attendance, when separated from the family and under the immediate and constant eye of a surgeon. He hoped any individual present, who had not yet subscribed to an institution which was popular with the labourer and with all classes of society, would lose no time in lending it his support. He begged they would now drink to the health of "Drs. MacCaragher and Forbes, and success to the Chichester Infirmary."

Dr. FORBES returned thanks, but in so low a tone as to be inaudible at the middle of the room.

Mr. J. BARTON rose and spoke at some length on agricultural statistics, advocating some plan for the cultivation of waste land and the better employment of capital; but we were not able to catch the thread of his remarks, and on his making allusion to Mr. Villiers' motion on the corn-laws, the Chairman interrupted him by observing that he must know he was touching on forbidden ground by the introduction of politics. It was of the greatest importance that when

they met they should abide by their rules, and avoid the introduction of any discussion on political questions, which would set every one against the other. Here all parties might meet upon neutral ground. He was ready to admit the great services which Mr. Barten had rendered to this institution, and to all the useful societies of Chichester, such as the Savings Bank, the Lancasterian School, &c., &c.; but as their Chairman, and therefore obliged to act without favour or affection, he was obliged to state that he thought he was going rather beyond the bounds of their rules.

The CHAIRMAN then said he wished them now to drink to that profession which, in the days when England's sons were called to foreign climes to fight her battles, exerted themselves to the utmost to maintain the honour and independence of the flag they had sworn to uphold. The British army had distinguished itself during the war, in every battle and in every land; and the greatest pride of British soldiers had been that they had maintained the honour and glory of the British arms and the British flag. He never wished to couple any toast with a political feeling, but he would ask whether there was any man in the world, who, when the British army was drunk, did not naturally look to that great general that had led them on to constant and never-failing victory. He begged them therefore to drink "health and long life to the Duke of Wellington and the British Army." (*Immense applause.*) And may we never want a man with like ability, talents, courage, and coolness to lead our armies in the time of war.—Drank with nine times nine.

The CHAIRMAN said they would now drink to the sister branch of the profession. This was a maritime county, and they knew well the advantage, in time of war, of having their coasts well guarded by the wooden walls of England. The members of this profession had ever rivalled their brethren in arms in mighty deeds; and if they had not had so many victories at the close of the war to boast of, it was because, in the early part, they had swept the seas of every enemy. He would couple with the Navy Lord Minto, and as he saw opposite to him a gallant Captain of this service, he could not conclude better than by drinking to Captain Pilkington's very good health.

Captain PILKINGTON was highly flattered by this individual attack made upon him, which he could not but consider in the light of a high compliment from his Grace. He had fought and bled for his country, and, he trusted, had done every thing to maintain the honour of the British flag in every quarter of the globe; and now that the arms of peace were spread around them, he and the members of the profession to which he belonged would always be found ready to patronize the tillers of the soil from thence they drew their breath, and to advance every thing tending to the welfare of the labouring population.

The CHAIRMAN said the next toast on his list was not a political one, but one intended not only as a compliment to their representatives, but also to those who send them to Parliament; it was to "the members for Chichester and Western Sussex," whose names would be found among their list of Vice-Presidents.

The CHAIRMAN said he liked a convivial meeting as well as any one; and he thought he had proved this by never missing an opportunity of being present among them. But they should take care that the excitement which they occasioned did not lead to any excess, contrary to the example and precepts which they were desirous of setting before their labourers. He had one other toast to propose before he left. It was that of a Society of which he had the honour to be President, formed for the sole purpose of promoting the culture of the soil, &c. The Royal Agricultural Society of England had only been established about two years, and ranked already amongst its members most of the influential farmers of England, numbering nearly 3000 members. It would shortly hold its general meeting at Cambridge; and he now begged they would drink prosperity to this Society, coupling with it the health of their late Secretary, Mr. Shaw.

Mr. W. SHAW rose and said, My Lord Duke and Gentlemen, seeing that there are many other members of the Royal Agricultural Society of England present, I could have wished that some more able advocate had been found to respond to the toast; but I could not hesitate a moment in returning thanks on behalf of that society with which you have done me the honour to associate my name, and which will, I trust, become a national institution and a national benefit. It is but little more than two years since I suggested the establishment of that Society to your Grace, through Earl Spencer; I have taken a deep interest in it, and no exertion will ever be wanting on my part to promote its success. I will not, at a meeting constituted for other purposes, as this is, dilate upon the objects of that society; there is one, however, of the objects, forming a part of the agricultural constitution of that Society, perfectly applicable to the business of this meeting, namely, "To promote the comfort and welfare of labourers, and to encourage the improved management of their cottages and gardens." It is true that little or nothing has as yet been done but much time is needed to arrange the machinery for carrying on such a society! The labourers, however, have not been forgotten, as a proposition for dividing the country into districts for the meetings of the society was discussed at considerable length at a late meeting of the Council; the object of that division being, in a great measure, a preparatory step to facilitate arrangements for giving encouragement and assistance to the labourer.

Mr. HOLIST had permission from their Chairman to propose a toast which he had often given on former occasions, and which had always been received with cordiality and enthusiasm. They had been honoured to-day, for the first time, with the presence of ladies to see the agricultural premiums distributed; and he ventured to affirm that had a lady of the highest rank and first name been in the neighbourhood, it would have delighted her to see the happy countenances of the labourers, to see how they were relieved, and to see how her noble husband was received among his friends, and how her noble son was walking in the footsteps of his father. (*Applause.*) Their noble Chairman, after he had laid down the sword and assumed the ploughshare, sought among his companions in arms for a sister or a daughter who could make his home and his after days happy; and he had found one who set an example which every farmer's wife would do well to imitate. He thought there was no indelicacy in mentioning the circumstance, for his Grace had often alluded to it in public; she had nursed every child that she had had, and they had imbibed with their mother's milk their mother's amiable disposition and excellent character. (*Applause.*) He felt that he should be unnecessarily detaining them at this late hour of the evening, were he to enter into further preface; and he would therefore give "the Duchess of Richmond," and may every unmarried farmer soon have as good a farmer's wife as the Duchess of Richmond. (*Cheers.*)

The CHAIRMAN felt very grateful for this kind remembrance of the Duchess. If she had been in the country, she would have been very glad to be present, and to see these honest labourers in their round frocks, made happy by the rewards they had justly gained. His grace then passed an eulogium on the peasantry of England when they were called into service in the army during the war. The officers fought for fame, for ambition, for glory and honour, and if victorious, were looked up to with admiration and respect; but how many poor men were there who had equally distinguished themselves for coolness and courage and bravery, and whose deeds were perhaps never heard of. Their highest object, then, was to do their duty in the station in which they were placed. He would never take any credit to himself, unless they awarded it to those also who had so gallantly supported him. It was very gratifying to him to have the approbation of those who had known him so long, and who never knew him guilty of a mean or dishonourable action, or of obtaining a cheer by saying what he did not mean. Thanking them all for coming here to-day, he hoped he should

be spared to preside again over them, and that they would rally round him next year.

His Grace and the greater part of the company then left the room, it being nearly seven o'clock. A large party, however, remained, Captain Pilkington being voted to the chair, and maintained the conviviality and harmony of the meeting until a late hour.

ON THE PLOUGH.

(FROM A CORRESPONDENT.)

Among the various subjects brought under the consideration of the Royal Agricultural Society of England, that of the plough may be justly considered of great importance, and when taken in reference to its usefulness, power, and the principle of its construction, must occupy a prominent place.

The experiments tried under the superintendence of Philip Pusey, Esq., and reported by him in the third part of the first volume of the Journal of the Society upon the above subject, are not only highly interesting, but exhibit a clearness of detail, and an industry and discrimination in the investigation of the subject truly laudable.

It is therefore with considerable diffidence that the following objections are submitted to the candid consideration of the Society.

Objection the first.—That although great merit is due to the constructors of the various instruments, and great ingenuity has been displayed, it is nevertheless to be doubted, if any of these referred to in the above report are formed upon a true mechanical principle.

Objection the second.—That the extreme shortness of the said instruments is such, as to require an angle quite at variance (it is apprehended) with the most approved application of mechanical power.

Objection the third.—That should it prove that the form of the said instruments is less objectionable than is now supposed, yet the wrists, or mould-

boards, being fixed, are calculated to limit the usefulness thereof; a plough with sliding wrists, removable at pleasure, being preferable.

First as to form.—The wedge or inclined plane is considered to be the *true*^{*} principle upon which a plough acts. The curved wrists or mould-boards therefore, of those referred to, are less adapted to effect their object, than one having straight sides, because the angle being unequal, the power of resistance is differently affected; the fore part of an instrument with curved sides, may advance easily because the angle is small, but the hinder part having greater obtuseness, its power to overcome resistance is much deteriorated.

The curved sides of a wedge may probably succeed sufficiently where the resistance is greater at the point, than toward the heel, as in cleaving logs, where the first entrance is the prime difficulty, but when that is overcome, the natural adhesion of the leg being partly destroyed, the resistance consequently diminishes as the wedge proceeds; but it is to be questioned if this applies to the operation of a plough, where the land separated offers a more uniform resistance, and produces a pressure nearly equal at every part; the angle therefore of the inclined plane, should be equal also throughout its whole length, that the pressure, whether vertical or lateral, may be equally overcome.

This it is presumed can be best accomplished by an instrument whose parts, in contact with the moving land, diverge every way from the share point in straight lines.

Second as to length.—The friction of a plough is not to be estimated altogether by its length. Although it may long have been a received opinion, that the shorter the plough, the sooner the contact with the land ceases, and therefore the lighter the draught, but if the separated land is required to be moved a certain distance, the *angle* of the instrument must be as *necessarily* considered as the *length*.

The following four figures of wedges, or inclined plans, represent the mechanical principle of the plough:—

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

* In an essay on ploughs by H. Handley, Esq., to which a premium was awarded by the Royal Agricultural Society of England at the Oxford meeting in July 1839, the author, in reference to Kent ploughs,

observes "they are confined to their respective localities, while it is questionable whether they will be much longer retained there, it is certain they will not become general in other parts." The farmers of Kent, however,

Figure 1 is the section of a Kent turn-wrist plough. The apex of this figure A is supposed to be the edge of the coulter, the line A B the land side of the plough and measures 5 feet in length, the line A C is the furrow side, the line B C the width from the land to the furrow side 15 inches, which the plough excavates each time it crosses the field, removing the furrow from the land to the other side.

Figure 2 is a section of any other plough with straight sides, is 4 feet long from A to C, and 15 inches wide from B to C.

Figure 3 is 3 feet long from A to C, and 15 inches wide from B to C.

Figure 4 is 3 feet long from A to C if measured in a straight line, and 15 inches wide from B to C, the same as figure 3, and varies therefrom only in the curvature of the line A C.

The angle of inclination of the two lines A B and A C is, in figure 1, $14\frac{1}{2}$ degrees, in figure 2, 19 degrees, in figure 3, $23\frac{1}{2}$ degrees.

The angle of figure 4 varies in its parts, being about the same as figure 1 in the fore part, but becomes more obtuse toward the hinder part, and finishes at an angle of 50 degrees, as described by the two lines D B and D E.

It will thus appear, that although a plough formed upon the scale of figure 1 remains in contact with the land it passes through in proportion of 5 to 3, when compared with figure 3, yet as the angle of the former is $14\frac{1}{2}$ degrees, and that of the latter $23\frac{1}{2}$, it is thought that the difference of angle will fully compensate for the greater length, and if the lateral pressure which is estimated at two-thirds of all the resistance, is also taken into consideration, it is presumed the advantage will remain with the former. At the same time length may be carried to excess in either way; an instrument 60 feet long for instance, would require an angle of $1\frac{1}{2}$ degrees to remove a furrow 15 inches, yet there can be no doubt but that the cumbersome length would counteract every advantage which could be derived from so small an angle.

Again, an instrument of 6 inches length would require an angle of 80 degrees to remove a furrow to an equal distance, and consequently could scarcely be forced through the land, and one of 90 degrees or a right angle would have the furrow bearing perpendicularly to the line A C, and could not pass at all.

Thirdly, the Kent or turnwrist plough, which forms a double wedge, (acting first vertically, and secondly, laterally) has several advantages over one with a fixed wrist or mould-board, in laying the land level instead of being thrown into ridges, which on dry land can be of no use, but on the contrary has a tendency to run the land to weeds both on the back or centre furrow, of the ridge or stetch, and also in every open furrow; should the ridges be narrow it must be most inconvenient for the application of the broadsharing system of cultivation, which is considered indispensable for the destruction of couchgrass, and also of annual weeds; so much so, that few persons that have once experienced its value will be inclined to relinquish it. Should the ridges be four rods wide, the time lost in turning will be equal to one day in twenty, in an enclosure of 40 rods square.

When the turnwrist plough is required for the purpose of broadsharing, it is simply to remove the wrists and change the point, or shares, from a plough-

can very well tolerate the reproach cast upon them, coming, as it does, from a gentleman, who, compares the action of a plough to that of a screw. See "seventh paragraph" of his essay.

ing one of 6 inches, to a broad one of 16 or $24\frac{1}{2}$ inches, which can be accomplished in ten minutes, and the plough is ready for work.

In case the land should be very adhesive in character, or very hard from continued drought, the turnwrist plough can do its work, when a sawing, or wheel plough with short mould-boards, or wrists, would be utterly useless.

It has been considered necessary in the foregoing views to fix the distance at which the furrow should be opened at 15 inches, to give room for the land separated to turn properly; suppose the furrow to be 6 inches deep, and 9 wide. The first motion performed by a turnwrist plough is the vertical action which sets the severed furrow on edge by sliding it up the share and back, in a straight line, which inclines in an angle of about 15 degrees with the bottom of the plough; the second motion which is forced upon the furrow, is to place it alongside of those previously done, bottom upwards, which action is performed by the wrist acting laterally.

A short mould-board, or wrist, must have an angle of $23\frac{1}{2}$ degrees to remove the furrow 15 inches, in which case it approaches the furrow in such an oblique direction, that instead of rolling the furrow over as it ought to do, it presses it forward, as well as sideways, performing two motions instead of one, thus causing greater friction than is required, and fully accounting for the small light ploughs requiring a larger proportion of propelling force than could be otherwise accounted for.

We have now to consider the power required to propel the instruments respectively, and this it will be advisable to ascertain by a full trial.

It may be observed in conclusion that the primary object on the subject of ploughs, should be their efficiency, and that the power required to put them in motion is but secondary. Let the plough therefore, that performs its work best, have all the merit allowed it, which a principal point is justly entitled to, and if a turnwrist plough can be produced which requires no greater power to propel it than others, and which performs its work equally well, (which point it is apprehended is gained by some of the implements now in use among the Kent farmers) the advantages already enumerated are, it is hoped, sufficient to claim for it the notice of the Royal Agricultural Society of England.

ON THE WAGES OF THE AGRICULTURAL LABOURER.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—In one of my former communications I asserted that the agricultural labourers on the continent were, generally speaking, not so badly off as their brethren in England; and that ever since the reign of Henry the Sixth, the condition of the rural population of this country has been getting worse and worse. I likewise said, that, with your permission I would, on some future occasion, prove the truth of these assertions.

It is completely mystifying the question, and is certainly unfair, to take the mere amount of money wages obtained by the foreign agricultural labourer, as I see done by "Justitia," without reference to the prices of the different articles of consumption. I, for one, should like to see our peasantry brought down (as it is termed, though the proper expression would be raised up) to the condition of the peasantry abroad. A few years back the government sent

a list of questions to the different British Consuls abroad, regarding the state of agriculture, and the condition of the population, in their different localities. Their answers were published by order of the House of Commons, and form a very useful volume. In giving the following extracts, I think it right to mention, that the answers, even from the same country, as France for instance, vary very much. In these cases I have, as near as possible, with regard to population &c., struck a general average of the whole country. It would appear then, that in France the common day labourer, receives on an average 4s. 9d. per week, and about $\frac{1}{2}$ more in harvest. The price of butchers' meat, is $\frac{1}{2}$ d. per lb., bread 1d. per lb., potatoes about 1d. the 3lb. In the majority of cases the labourer is lodged, and sometimes boarded, by the farmer. Drees cheaper than in England. Very few paupers.

In Prussia, the wages of a day labourer are about 3s. a week, with a dwelling free. A day labourer with his family may cost the proprietor about 14l. 12s. 8d. a year. He receives for thrashing corn from the 11th to the 16th bushel, it varying in the different districts. In harvest the wages are half as much again, &c. Pasture for a cow in summer, a small load of hay for fodder in winter, with free fuel. Prices of butchers' meat $\frac{2}{3}$ d. per lb. Wheat bread 1d. per lb. Rye bread $\frac{1}{2}$ d. per lb. Butter $\frac{1}{2}$ d. per lb. Very few paupers.

In Germany the wages of a day labourer are 7d. to 9d. a day. A free dwelling in a cottage, a cabbage garden, a piece of ground equal to $\frac{1}{2}$ of an acre for potatoes. Fodder for a cow, sixteen bushels of rye, eight bushels of wheat, fuel free, &c. In harvest the wages are 10d. to 1s. per day. Price of beef $\frac{2}{3}$ d. to $\frac{3}{4}$ d. per lb. Mutton $\frac{2}{3}$ d. to 3d. per lb. Wheat bread 1d. to $\frac{1}{2}$ d. per lb. Rye bread $\frac{1}{2}$ d. to $\frac{3}{4}$ d. per lb. Butter $\frac{1}{2}$ d. to 5d. per lb. Cheese 1d. per lb.; beer 1d. the quart; potatoes 1s. 6d. per ton; clothes cheaper than in England.

In Holland and Belgium, the wages of a day labourer average about 5s. 6d. per week; about 1s. 6d. per week extra in harvest; price of beef 3d. per lb.; bread $\frac{1}{2}$ d. per lb.; potatoes 1s. 8d. per 40lbs.

In Italy and the Austrian States the wages of a day labourer are 1s. per day, if board and lodging is given half is deducted; price of beef $\frac{3}{4}$ d. per lb.; mutton 3d. per lb.; pork 3d. per lb.; butter 8d. per lb.; cheese 8d. per lb.; bread $\frac{1}{2}$ d. per lb. The consul at Trieste concludes his report by saying that the poorer cultivators are undoubtedly better off, than the day labourers in England.

The above are the wages obtained by the inferior kind of day labourers on the continent. Shepherds, carmen, &c., are paid considerably more.

I do not think that I shall be accused of under-rating the wages obtained by the common English day labourer, in setting them down at 9s. per week ("Jestitia" says 8s.), from which we must deduct 1s. 9d. per week for cottage rent, (in nearly all places on the continent, the labourer is provided with a cottage free) thus leaving 7s. 3d. to provide himself with the necessities of life. Bread has been on the average of the last three years, $\frac{2}{3}$ d. per lb.; meat $\frac{1}{2}$ d. per lb.; butter 1s. per lb.; cheese 10d. per lb.; potatoes $\frac{1}{2}$ d. per lb.; so that although the money price of labour in England is considerably higher than in any country of Europe, yet the quantity of the different articles of consumption obtainable is less: thus—

In England the labourer can obtain for 7s. 3d. either 39lbs. bread; 11 $\frac{1}{2}$ lbs. meat; 7 $\frac{1}{2}$ lbs. butter; 8 $\frac{1}{2}$ lbs. cheese; or 174lbs. potatoes.

In France with 4s. 9d. per week, either 46lbs. bread; 13 $\frac{1}{2}$ lbs. meat; or 261lbs. potatoes.

In Prussia, with 3s. per week, either 36lb. bread; 16lb. meat; or 8 $\frac{1}{2}$ lb. butter.

In Germany, with 4s. 6d. per week, either 43 $\frac{1}{2}$ lbs. bread; 18lbs. meat; 11 $\frac{1}{2}$ lb. butter; 54lb. cheese; or 54 quarts beer.

In Holland and Belgium, with 5s. 6d. per week, either, 58lbs. bread; 22lbs. beef; or 460lbs. potatoes.

In Italy and the Austrian States, with 6s. (or 5s. 3d. per week, including lodging,) either 50lbs. bread; 21lb. meat; 8lbs. butter; 8lbs. cheese; or 168lbs. potatoes.

In taking the above countries I have not chosen them out from others, but have given every one from which there was any report.

With regard to the second assertion, viz., "that ever since the reign of Henry the Sixth (or I might have taken a still earlier period) the condition of the rural population of this country has been getting worse and worse," it is only necessary to give an extract from "Hallam's history of the middle ages," to put the question entirely at rest, he says:—

"There is one very unpleasant remark which every-one who attends to the subject of prices will be induced to make, that the labouring classes, especially those engaged in agriculture, were better provided with the means of subsistence in the reign of Edward the Third, or of Henry the Sixth, than they are at present. In the fourteenth century Sir John Cullum observes, a harvest man had four-pence a day which enables him in a week to buy a comb of wheat, but to buy a comb of wheat, a man must now (1784*) work ten or twelve days. So, under Henry the Sixth, if meat was at a farthing and a half a pound, which I suppose was about the truth, a labourer earning three-pence a day, or eighteen-pence a week, could buy a bushel of Wheat, at six shillings the quarter, and twenty-four pounds of meat for his family. A labourer at present, earning twelve shillings a week, can only buy half a bushel of wheat, at eighty shillings the quarter, and twelve of meat at seven-pence. Several acts of parliament, regulate the wages that might be paid to labourers of different kinds. Thus the statute of labourers, in 1350, fixed the wages of reapers during harvest at three-pence a day without diet, equal to five shillings at present; that of 23 H. VI., c. 12, in 1444, fixed the reapers' wages at fivepence, and those of common workmen in building at $\frac{3}{4}$ d., equal to 6s. 8d. and 4s. 8d.; the yearly wages of a chief hind or shepherd, were 1l. 4s., equivalent to about 20l.; those of a common servant in husbandry, 18s. 4d. with meat and drink; they were somewhat augmented by the statute 1496. I should find it difficult to result the conclusion, that however the labourer has derived benefit from the cheapness of manufactured commodities, and from many inventions of common utility, he is much inferior in ability to support a family to his ancestors three or four centuries ago. I know not why some have supposed that meat was a luxury seldom obtained by the labourer. Doubtless he could not have obtained as much as he pleased; but from the greater cheapness of cattle as compared with corn, it seems to follow that a more considerable portion of his ordinary diet consisted of animal food than at present. It was remarked by Sir John Fortescue, that the English lived far more upon animal diet than their rivals the French; and it was natural to ascribe their superior strength and courage to this cause.

* It will be seen that the data which Mr. Hallam takes as existing in 1784 is rather more favourable to the labourer, than if compared with the present time.

Thus, there can be no doubt but what the condition of the English Agricultural labourer has greatly deteriorated, and whilst they have been sinking lower into poverty and misery, the already wealthy aristocracy have become more wealthy, and there has arisen a middle class,—a state of society nearly unknown to the times of Edward the Third, the halcyon days of the English peasant, which class has been gradually increasing in wealth and power, whilst the men who have lent their strong aid towards its attainments, have sunk into such a state of wretchedness, that no change, whatever it may be, can make their condition worse.

I intended to have shown a few of the fallacies contained in a letter signed "Justitia," published in your paper a few weeks back, but I have already taken up too much of your valuable room.

May 20th.

JUSTICE.

Six,—On perusing the arguments of the opponents to agricultural protection, every disinterested person must be induced to believe, that the sole objects of the agriculturists, in desiring a continuance of that protection, is to keep up the price of bread, merely to starve the labouring classes, both agricultural and manufacturing, and even in opposition to their own interests; and, above all, when they have obtained their object, to dole out a miserable starvation pittance to the labourer weekly, in the shape of wages; and to add insult to injury by calling it a remuneration for his labour. This seems in itself so cruel, that it is not to be wondered at that the feelings of the humane, whether in town or country, acquainted or not with agricultural affairs, should rise indignant and exclaim—"Good God! are these things so?—and are the agriculturists striving for a continuance of this wretchedness?" The answer, of course, is given in the affirmative, and the silence of the farmer seems to admit the fact, that he is not able to defend his case.

But it should be borne in mind, that the generality of farmers are by no means a ready portion of the community. Their avocation requires their daily and hourly attention, and, although the *Mark Lane Express* has a most extensive circulation, still it may not be unfair to calculate, that certainly not one in fifty—nay, perhaps not one in a hundred—ever peruse its pages. Thus a large portion of them are not made aware of the charges laid against them; and most of those who are, consider them underserving a serious refutation, and suffer the matter to pass, as it were, unnoticed; and thus, through ignorance on one hand, and indifference on the other, they seem to stand convicted by their opponents, of all these enormities, without exception of persons or places.

The apparent difference in the amount of wages given in different districts to the agricultural labourer, and without any ostensible reason being assigned, has been productive of much animadversion, through the medium of your columns, and every person connected with agricultural pursuits can but feel surprised at the statements given by some of your correspondents, and would willingly doubt the truth, and have expected to see such statements contradicted. I will venture to affirm, that in no one place in the county of Kent have less wages been given than two shillings per day for years past. Upon this sum all calculations for piece-work prices are made, and I scarcely have known a man earn less than from 13s. to 16s. per week, when working by the piece, since the summer of 1823, bad weather excepted. I am now speaking of my own workmen,

and I am giving no higher wages than others around me. Some persons, I perceive, in the middle, eastern, and southern districts, where a proper rate of wages is given, have felt indignant at the charge, and have repelled the attack by stating the amount they are in the habit of giving. But, as W. S. very justly observes, that the proper prices given in some districts does not militate against its first position, viz., that there are districts, &c., &c., and the question which naturally arises is, that, as the farmers of those districts make as much of their produce as the farmers of the before-mentioned districts, why are they not to give the same rate of wages, and more, especially as they well know that the highest is barely sufficient? Surely the grave charge of giving able-bodied labourers no more than seven or eight shillings per week, if untrue, is worth the trouble of refutation, and let the public mind be disabused. However, in candour to them, we must put this construction upon their silence, that they are, for the most part, unacquainted with the charge, and that there is no doubt those labourers are paid, partly in kind and partly in cash. As to supposing the labourers in those districts are lazy, and therefore unworthy of higher wages, is both absurd and uncharitable. There are good and bad labourers in every district, but many more good than bad. As to Lincolnshire, there is no doubt, if everything is taken into the account, the wages given there are not greater than in several other counties. It does not appear that, in those districts, where such low wages are given, that it has been productive of any serious discontent, of any mutiny or disobedience to the laws. It is, therefore, inferable, that the apparent difference is made up to the labourer in some way or other, and that their condition is thereby rendered equal to those in districts where higher wages are given. It may, therefore, be asked, if the labourers are content, what right has any one to enquire as to the particular means employed to render them so? Admitting the case to stand so, still, as it appears to have been taken up through a good feeling towards the poor, a little explanation from those districts accused of giving inadequate wages might have prevented so much discussion. Now a custom prevails in some places, in giving the labourer a portion of his wages in kind (as it is often termed)—that is, in wheat or flour, in order to secure bread for the children; and this has been proved to be a salutary method; and, that it might not appear to be pointedly done toward some few individuals, it was made a rule in general, the same as in the administering parochial relief. Whether this or some such method prevails in certain districts does not appear, nor does the rhodomontade story of the Devonshire farmer, about drinking cider in harvest, afford any conclusive evidence that good wages are there given, even if the cider is taken into the account. The reason given by the agriculturists for a continuance of the protecting duties is, to be enabled to pay their workmen such wages as will afford them the means of living a little better than the Prussian serf. If the public agree in this, and make it one of the reasons for their permitting a continuance of this protection, have they not a right, in some degree, to enquire a little whether such wages are given, and without going at all into particulars, especially when such statements appear in the public prints as that given by the Rev. Mr. Fergusson?

Another argument, advanced by some in these low-priced districts, as a reason for giving such wages, is the superabundance of labourers in the market (as it is termed), and that the price of labour, like all other commodities, must be ruled by supply and

demand, and that every person has a right to get his labour performed at the lowest price he can screw the labourer down to. Away with such nonsense! is this the way to have industrious men, and to promote that good feeling that used formerly to exist, when every labourer held his employer's interest at heart? Certainly not! If this labour-market maxim prevails in large towns (London, for instance), where all are, as it were, strangers to each other, for Heaven's sake! banish such sophistry from the rural districts, and let man be the friend of man. The man who reduces the wages of the defenceless poor below, what is just and equitable, would pay no man to whom he is indebted if he could avoid it. Poverty will sometimes compel a man to do what he would not do under other circumstances, and even the poor themselves will excuse an employer, when they know that is the case; but this cannot be the case with whole districts. And is it the fault of the poor that they are not fully employed, and that this great resource of national wealth is so much neglected? Are they not made the victims of a bad policy, where they might become (if their labours were properly directed) the greatest blessing to the country? What nation can boast of a peasantry equal to them in industry? Witness those places where the allotment system has been introduced. Carry out that system to the greatest extent it is capable of, and you will hear little more of the labour market. If you cannot find employment for all, give to those you do employ what is just and equitable between man and man. That this is conscientiously done by thousands, there is not the shadow of a doubt; and why not by all? Has any satisfactory reason been assigned, why they should not? And if they have, why not explain? Is not the cause of the helpless poor the cause of every humane person in the kingdom? Or must no one open his lips in their defence? Justice must acknowledge this. Emigration, so much recommended by some, can never bring about the good that is sought, make it as extensive as you please. It is beginning at the wrong end; it might, perhaps, mitigate the evil a trifle for a short time, but it would never work a cure in their present condition. Improve that, give them the means, and their own energies will redeem them from pauperism. They would seek and obtain education for themselves in thousands of instances, and when they are educated (even in the plainest and most simple acceptation of the term), numbers will emigrate of their own accord, especially when they are made sensible of their own competency of improving their circumstances thereby. All this must be a work of time, but the lasting benefits it would confer on the whole community would be felt by, and receive the praise of, future ages, and might reduce the necessity there appears to be, for providing separate burying grounds to the extent now in contemplation.

June 9, 1840.

A YEOMAN OF KENT.

SIR.—I think both W. S. and Justice have successfully maintained their position, viz. "that there are districts where agricultural labourers' wages do not exceed eight or nine shillings per week;" this assertion was made, I believe, only with regard to the cheaper counties; but what was my astonishment, when passing through some parts of Buckinghamshire within thirty miles of London a short time since, to find that in that neighbourhood where meat, bread, and indeed all the necessaries of life are as dear as in London, (and fifty per cent. dearer than the counties of Somerset, Dorset, and Devon,) that labourers were only paid ten shillings per week.

Let me ask those advocates for continued oppression how is a man, his wife, and three or four children, to be maintained on such a sum? for mark me, there is no cider made in this neighbourhood with which to wash out their starving bellies, so much boasted of by a Devonshire Farmer. I dare say some philanthropic soul will furnish me with a solution of this enigma; but I confess that at present I am at a loss to ascertain how, after deducting, say four shillings a week for rent, clothes, soap, medicine, &c. &c., the remaining six is to furnish for five persons, three meals per day, making together 105 meals per week, which amounts to not quite three farthings per meal; perhaps I shall not be believed I say that I have boys in my employ who could eat nearly that amount (viz. six shillings per week) in bread alone, provided they had nothing else.

I will not trespass longer on your valuable columns merely than to observe that though no blame attaches itself to the farmer in paying these wages, as he must purchase labour like everything else at the cheapest market, and the present rate of wages will doubtless continue until the system is changed, yet I think a man who dwelling in plenty can sit down and write such stuff as has appeared in your paper lately, must be unfeeling indeed, and the severest punishment I could wish him would be that he should live for twelve months on three farthings per meal. I remain, Sir,

A SUBSCRIBER.

Bromley New Town, Middlesex, June 8th.

THE FARMERS' AND GENERAL FIRE AND LIFE INSURANCE INSTITUTION.—

We are requested to state that in addition to the noblemen and gentlemen, whose names are given in our advertising sheet, His Grace the Duke of Rutland has consented to act as Honorary Director for this Institution.

A CHALLENGE.

SIR,—On reading your report of the Exeter Agricultural Society's Show on Monday, June 8th, I see Sir Thomas Ackland stated that his friends Mr. John Gould and Mr. Wippell declared to him they were not satisfied with the Devon stock exhibited at the Oxford show; Sir Thomas also states that one man from Somerset carried off prize after prize with animals that grazed on the breezy hills of his county. On that point I beg to say he has been misinformed, for all the animals with which I gained prizes were bred by myself, and never saw a breezy Devonshire hill, except the old bull, which was bred by the late Mr. Wm. Davy, of Flitton, North Moulton.

Now, sir, I beg to offer this challenge: I will show fifty or eighty head of Devon cattle, all one man's property, for fifty or eighty guineas, against Sir Thomas Ackland, if he is a breeder of such, Mr. Gould, or Mr. Wippell, any day within one month. I will also go farther, to give the Devonshire breeders time to improve; I will undertake to show 100 head of Devon heifers, cows, and bulls, at Michaelmas, 1842, against any man in Devonshire or all England, for 100 guineas each, all to be bred by, and the property of, one person; the judges to be chosen in the usual way. Any man that will accept this offer, to give me notice in three months from the date hereof.

I am, Sir, your obedient servant,

MATTHEW PAULL.

Compton Pauncefoot, June 20th, 1840.

AGRICULTURAL REPORTS.

GENERAL AGRICULTURAL REPORT FOR JUNE.

In taking a retrospective glance at the progress made in the growing crops, and the great improvement apparent in the whole vegetable creation, we conceive there never was a period, within the memory of the oldest man living, in which such surprising, and at the same time truly beneficial, changes have been effected in the same space of time, as has been the case since the date of our last report; and, sure we are, that all engaged in, or in any way connected with agriculture, will bear us out in our observations, when we assert, that with some few exceptions on the more backward soils (exceptions invariably found at all corresponding seasons of the year), the young wheat plants have scarcely ever experienced such firmness and rapidity of growth, coupled with so large a number of healthy off-shoots, as has been observable of late; while the atmospheric temperature has proved unquestionably the most propitious to vegetation in the most unlimited sense of the word, that could possibly have been experienced. These remarks, it must be understood, are not the offspring of theory: but are deduced from the opinions of practical men, and, it may be added, the majority of the most eminent and extensive grain producers in the kingdom; as well, in fact, as from personal experience and observation. Hence, we have to congratulate our farmers upon the prospect of the wheat harvest being commenced at least a fortnight earlier than was that of last year, the plants of that valuable description of grain being already in full bloom in several parts of the western, southern, and midland counties, whilst north of the Humber they are rapidly coming into full ear.

With respect to the probable produce, it must be honestly confessed we are not so sanguine in our expectations as some persons have been led to imagine, since it must be borne in mind that the autumnal seed time was, perhaps, from the unusually large quantity of rain which fell in November, together with the necessary postponement of the sowing the heavy wheats till the usual period is generally considered at an end, have not only tended to greatly perplex the agriculturists, but must inevitably have had a by no means wholesome effect upon the young wheats. Still, however, we trust with the aid of fine weather, that the yield will in most instances, come up to a fair average; beyond which, our expectations do not extend. As to barley and oats, we regret to say that the accounts which have reached us from Suffolk are not very flattering; nevertheless the crops of that variety of corn, as also those of oats, are progressing rapidly toward maturity. Both beans and peas appear to have suffered from the long continued drought, at the time planting usually takes place; hence partial failures have taken place.

The hay harvest has, at length, become pretty general, and stacks are rising rapidly in good situations; but owing to the thin swathe it is expected to fall considerably short of that of many preceding seasons, in consequence of which, old qualities are held at high prices, without much probability of any decline taking place for some time hence.

In our grazing districts, a great number of losses have taken place, arising from the so long com-

plained of epidemic, notwithstanding the many remedies which have been adopted by our graziers, many of which, we are happy to state, have proved successful, particularly as relates to those suggested through the medium of the Royal Agricultural Society.

From most parts we have received intimation of the produce of the old wheats having proved somewhat on the increase, and of very superior quality, while the samples brought forward in the various markets of consumption have exhibited a great improvement. Good parcels have commanded a steady inquiry at, in most transactions, an advance of fully 1s. per quarter; and there has been a decidedly better feeling in the inquiry for the middling and inferior descriptions. The mating season having been brought to a close, very little business has been doing in barley, yet the prices have been tolerably well supported. Oats, on the contrary, have gone off steadily, at about previous rates. In beans and peas little doing.

Throughout Ireland and Scotland, the weather has continued fine, and the wheat, barley, and oats have experienced very little interruption in the shape of superabundant moisture. All farm labours are well in their place, and the intelligence is, on the whole, highly satisfactory.

The following is our usual statement of the supplies and prices of fat-stock, exhibited and sold in Smithfield Cattle-market, during the month.

The supplies of beasts have consisted of 10,429; of sheep and lambs, 110,468; of calves, 980; and of pigs, 1284; while the prices have ranged as follows:—Beef, from 3s. 2d. to 4s. 10d.; mutton, 3s. 6d. to 4s. 8d.; lamb, 5s. to 6s. 4d.; veal, 4s. 4d. to 5s. 4d.; and pork, 4s. to 4s. 8d. per 8lbs. to sink the offals. All kinds of prime stock have sold briskly, at improving rates, but in middling and inferior kinds little has been doing. From Scotland the receipts have amounted to 420 horned and polled Scots; from the Isle of Wight, 600 lambs, the whole of which have come to hand in good saleable condition, and produced fair currencies.

A STATEMENT AND COMPARISON of the SUPPLIES and PRICES of FAT STOCK, exhibited and sold in SMITHFIELD CATTLE MARKET, on Monday, June 24, 1839, and Monday, June 22, 1840.

As is almost invariably the case during the sum.

mer months, a considerable falling off has taken place in the arrivals of country slaughtered meat up to Newgate and Leadenhall markets, they having comprised only 90 carcasses of beef; 380 ditto of mutton; 140 ditto of veal; and 800 ditto of pork, with which the trade has been firm.

ESSEX.

We have this month to report the prospect of as fine a crop in our county, of every description, as can be reasonably wished. We believe the land will do its best, from the succession of the most genial weather possible. The wheats have come into ear rather short, which, in some measure, may be accounted for by its standing thicker on the ground than usual. We may say of every description of grain, as well as of grass, mangold, turnips, &c., we never, on the whole, saw them more promising. Haying has commenced partially in our district, and the swaths have fallen heavily; next week there will, no doubt, be a general beginning. We shall not be at all surprised at hearing of new samples of corn being in the market previous to the 1st of August, as, if the weather should continue warm and fine, we may calculate upon beginning by the latter end of July, some of our pieces, which are in bloom. Oats are rapidly coming out into ear, as well as barley, peas, &c. On the latter, blight has made its appearance, but we do not anticipate any very great injury, as the blossoms are too far advanced. A considerable quantity of nitrate of soda, as well as nitre, has been used on the wheat as a top-dressing, and in its effect is very visible, the blade appearing very green, and the wheat-ear, in some cases, at least twelve inches higher than where the dressing was not given; having applied it on twenty acres this season, we shall be curious to know whether the yield of grain will be equal to the increase of the straw, and intend thrashing out the dressed and undressed in the same field, to get at the result. If it turns out as superior, as its appearance warrants us to expect, we shall adopt it as one of the cheapest manures attainable by the farmer. Sheep-shearing is drawing to a close with us, and the clip, we imagine, will be heavy: a poor remuneration is held out as yet to the seller. We are rather anxiously waiting the show of the English Agricultural Society, at Cambridge, as promising a rich treat, and we would advise every farmer who can spare the time to avail himself of the opportunity to see one of the finest and most interesting exhibitions he ever witnessed.

SUFFOLK.

In forwarding a report at this season of the year, of the state and prospects of the growing crops, it is

necessary to use great caution, as from the appearance of the crop, and the state of the weather from now until the fruits of the earth are in-gathered, the prices of the various grain are estimated in a great measure, particularly with regard to the staff of life, or perhaps we ought to have said from what it is produced, wheat. We are happy to have to report of this county that the prospect is good; we see no fear to anticipate less than a fair average. Indeed, if we were to judge only from the appearance in passing, we should be induced to say they are beyond an average aspect, but on examination, it is found in the majority of cases most kinds of crops are *road proud*. Mangel wurzel plants particularly well, and the breadth prepared for that valuable root is yearly increasing. Swedes are also sown under very auspicious circumstances; we allude to the fine tilth into which the attentive farmer was enabled to get his land, but we hear great complaint of their being taken off by the fly; there is yet good time to sow with hybrid, which is nearly as valuable as the Swede, also with the various kinds of later or common turnip. The clovers are generally very short, so are the meadows; therefore it behoves the provident farmer to try to make some provision for winter provender. Potatoes are this year the lightest we have remembered them for several years. There are more experiments tried this year with artificial manures than was ever before known. Nitrate of soda we think is the favourite at present, as that appears to cause improvement on all descriptions of land; whether that improvement in the bulk of straw will also be realized in the increase of grain, is yet to be proved; we anticipate it will, and that it must prove an ultimate benefit to these who use it. The result of the majority of these trials we hope, will be communicated through the same source by which the parties were induced to make them, viz.:—the farmer's clubs which are springing up and continuing to increase in this county in every direction. Of the utility of farmers' clubs, I think the following anecdote is an illustration. A gentleman farmer (and a first-rate practical agriculturist too) on being solicited to join a farmers' club lately established in his neighbourhood, on learning what was the intention and the benefits to be imparted by farmers' clubs, thought to himself, I am one of the best farmers hereabout, and what can I learn by attending a farmer's club; no one can tell me more than I already know about farming in all its bearings, but I will go and hear what they say and do. He attended once, and again, and again, and at the annual meeting made the above statement also, and that he never had attended one meeting without learning *something*, and said, he now thought himself but a *child* in the affairs and knowledge of agriculture.—June 19.

AGRICULTURAL INTELLIGENCE, FAIRS, &c.

RET福德 FAIR, June 18.—This fair for the sale of cattle, sheep, and horses was held yesterday, and in every respect far exceeded the most sanguine expectations of its most strenuous advocates. The difficulties attendant on the establishment of any new fair is sufficiently obvious, without our taking upon ourselves the task of so doing, but the inhabitants of Retford and the surrounding country never anticipated that such could be surmounted with such a little trouble, and its ultimate success thus placed beyond the possibility of any reasonable doubt. We are aware that very contradictory opinions have been held as to the exact period at which it should be held; but from the large attendance

of buyers and sellers yesterday, and the large quantity of stock and sheep exhibited, it was sufficiently apparent that a fair was necessary, and that the exact period of holding it was well-timed, and very judiciously chosen. The fair was held as advertised, on the Spa Common, which at an early hour had a very busy and imposing appearance. Upwards of 650 sheep were penned, the greatest part of which were either fat, or in good condition, nearly the whole of which found purchasers at remunerating prices. With respect to the number of cattle about 500 head were exhibited, amongst which, however, there were not many fat ones. Good fresh stock realized high prices, and nearly all sold. We had

many buyers from a considerable distance, all, or most of whom, expressed their astonishment at the importance which this fair, at its commencement, had assumed; and we are quite sure that the residents of the town were highly gratified at the prospect of its establishment, which must ultimately tend to the benefit of the inhabitants generally, of this highly important and well-cultivated district.

BRADFORD FAIR.—The show of horned cattle has been less than usual at this fair, which commenced on Wednesday. There were some good ones shown, and present calvers brought high prices. Lean cattle in considerable numbers, and were heavy on the market. There was an unusual show of good draught horses, and many changed hands, but the reduction in price from last summer is very considerable.

ROSSLY HILL FAIR.—This fair was a very good one, and the show of horses excellent and numerous. Light horses, fit for hacks and coaches, were in great demand, and brought good prices; heavy draught horses were a drug, and not much business done amongst them. The show of cattle was limited, for milch cows a great demand, and high prices obtained; beasts of all descriptions sold well.

THE AYLESBURY ANNUAL CATTLE FAIR on Monday last was well supplied with Horses, but none of a superior description. The sales were dull, and at prices corresponding. The supply of Sheep and Lambs was large, and met a ready sale from London buyers, to which place these were sent per railway.

THORNE JUNE FAIR.—There was a good attendance of buyers, and a tolerably good show of cattle, especially of lean stock, most of which was disposed of at prices a shade under those that have ruled at most of the late fairs. The show of horses was very indifferent, and altogether unworthy of notice.

TRINITY MUIR FAIR.—This great market commenced on Wednesday last, with the sale of sheep, the demand for which was brisk, and nearly all sold at high prices. Three-year-old hill wethers brought from 18*l.* to 22*l.*; fat do., from 27*l.* to 32*l.* 10*s.*; and ewes and lambs, from 11*l.* to 21*l.* per score. There was a fine show of cattle on Thursday, and much business done; but the supply was more than equal to the demand, and a large number of beasts was left unsold. Prime fat brought 8*s.*; current, 7*s.* 6*d.* per Dutch stone, to sink offals.—Small two and three-year-old stots and queys brought more money than heavy stock, according to weight and quality. The best three-year-old polled stots, twenty in number, sold by Mr. Mustard, of Leuchland, brought about 19*l.*, and the best two-year-olds about 13*l.* 10*s.* per head. Cows near calving were in good demand, and brought nearly former prices. The drave beasts from the northern counties brought 12*l.* to 16*l.*, but the dealers complained that they were losing money. The market, upon the whole, was much duller than expectation had conceived, and there were few buyers from the south. Prices were considerably lower than at some of the recent fairs in the neighbourhood.

MR. GEORGE TURNER'S ANNUAL SALE, &c., OF RAMS.—The annual sale, and letting of rams, the property of Mr. George Turner, took place at the residence of that gentleman, Barton, Exminster, on the 9th inst., and was largely attended by gentlemen and yeomen, from every part of this, as well as from the adjoining counties. Mr. Hussey was the auctioneer, and both sale and letting spoke most honourably for the judgment of Mr. Turner, in his selection of stock, as also that we think the result must have been highly satisfactory to him. The following may be given as instances of the prices obtained.—**Son.**—Ram, No. 36, to Mr. Tremayne, for 22*l.* 1*s.*—No. 40, to Mr. Samuel Pridham, Cheriton Fitzpayne, for 19*l.* 19*s.*—No. 39, to Mr. Thomas Melhuish, Poughill, for 14*l.* 14*s.*—No. 35, to Mr. Tremlett, Newton St. Cyres, for 13*l.* 2*s.* 6*d.*—No. 27, to Mr. George Mortimer, Ide, for 9*l.* 9*s.*—**Let.**—No. 45, to John Nott, Esq., Swymbridge, for 25*l.* 4*s.*—No. 1, to Mr. Pridham, Cheriton Fitzpayne, for 21*l.*—No. 6, to Mr. John Turner, Cheriton Fitzpayne 13*l.* 2*s.* 6*d.*—No. 7, to Mr. Chapple, Ottery St.

Mary, for 11*l.* 11*s.*—No. 2, to Mr. J. Anning, Kenn, for 10*l.* 10*s.*—And as a summary of the whole, we may state, that 31 Rams were sold for 278*l.* 15*s.* 6*d.*; and 8*l.* let, for 118*l.* 13*s.* The total proceeds being 397*l.* 8*s.* 6*d.*

ILMINSTER.—SHEEP-SHEARING.—The Founts annual sheep-shearing match came off with great spirit on Tuesday the 3d ult., and very good workmanship was displayed in that department of labour by the many competitors for the several prizes offered. The names of the successful candidates and the premium distributed are as follow:—

	£	s.
1st.—Thomas Slade, Beer Crocombe	3	0
2nd.—John England, Shepton, Beauchamp	2	0
3rd.—John Collins, Kingsbury	1	0
4th.—Charles Crabb, Tharbeer	0	15
5th.—Daniel Crabb, Beer Crocombe	0	10
6th.—John Tett, Hulsh, near Crewkerne	0	7
7th.—John Thorae Paul, Witherhay	0	5
8th.—John Barrett, Hambridge	0	3

After the labour of the day was over, the company and their friends retired to the Plough Inn, Founts Cross, to partake of a bountiful repast in the shape of a good substantial English dinner, provided by Mr. England. Mr. Thomas Stephens, of Atherston, officiated as chairman, and Mr. Phelps as vice-president. After the cloth was removed, the chairman rose and observed, that the association whose interest they were that day met to promote, had for its object the welfare of the agricultural population at large; it held out encouragement to the labourer, and ensured more attention to the manner in which the labour was performed; thereby the master would ultimately be much benefited by the means they were adopting. He was pleased with the day's proceedings thus far, and he hoped the remainder of it would be spent in the greatest harmony; he would therefore give the healths of her most gracious Majesty the Queen and Prince Albert, which were responded to with due honours. The Army and Navy was then given by R. Edmonds, Esq., and acknowledged by Messrs. Lang and Cannicott. Success to Agriculture, by Mr. Dibble, who, as one of the oldest agriculturists in the county, rejoiced that agriculture was brought to such a state of perfection, although he had no doubt but it could be much improved; when he saw such men as the Duke of Richmond, Earl Spencer, and others, patronizing these societies, he fully believed that constant improvements would be made. The umpires, Mr. J. Cannicott, Mr. Wallace, and Mr. Humphry, were then proposed and drank with great applause. Mr. Wallace responded to the toast, and said that the task which they had engaged to perform was not at all times a pleasant one, but it was one which they had performed, strictly adhering to the principle of duty and honesty. He hoped the society would flourish, and he should be happy, in conjunction with his fellow helpers, to render any assistance in his power at any future period. The health of the Chairman was then given by R. Edmonds, Esq. The health of Mr. Phelps, Vice-President, was also given with nine times nine. "Trade and Commerce" was proposed by Mr. W. Stephens. Mr. S. Stephens, of Ilminster, in acknowledging the compliment, observed that he delighted to identify himself with agriculturists, because he thought that the commercial and agricultural interests were so closely connected that they must stand or fall together. The health of Mr. England, the landlord, was then drank, who very appropriately acknowledged the toast and returned thanks. During the evening many other toasts were drank and duly responded to, which being interspersed with several songs suitable to the occasion, the enjoyment of the evening passed over in the most pleasant manner. Our limits will not allow of our giving a more lengthy report of these interesting proceedings. We would just observe that the amount of subscriptions raised by the company then present authorizes us to state the committee will be enabled to offer much higher prizes for the candidates at the next annual shearing match.

REVIEW OF THE CORN TRADE DURING THE MONTH OF JUNE.

Since our review for the month of May, of the state and prospects of agriculture during that month, the anti corn-law advocates have had another discussion on that most important subject, in the House of Lords, and certainly no new arguments in favour of the repeal of those protective enactments, so valuable to the united interests of all classes in the British empire, were produced by the different speakers on that occasion.

The old antiquated doctrine of reciprocity in trade, again formed the chief nucleus for their arguments, and the whole performance ended, from necessity, in a perfect failure, even in stage effect. The old complaint that *Foreigners, the producers of grains, are prevented from using our manufactures by our system of supplying our own population with all the necessities, and with many of the luxuries of life*, has been completely removed by the experience of a virtual free foreign corn trade during the last two years, for, so far from that freedom having been, in the slightest degree, beneficial to the manufacturing and commercial classes, its consequences have been perfectly the reverse. The partial failure in our home crops, during the last two corn seasons, has occasioned a correspondent failure in the home consumption of British manufactured goods, and during the same period, there has been certainly no increase in the exportation of these articles, to those foreign countries, from which we have lately been compelled to draw supplies of grain, to make good the deficiency in our growth. Even the demand for the United States of America, has received no spur from this unfortunate state of our affairs at home. The heavy debts due for several years now, by American merchants, to those of the United Kingdom, have not been in the smallest degree alleviated by the large importation which has occurred, from these causes, of American flour, nor was it likely that the American agriculturists would have parted with their property for any such patriotic purposes. Like the rest of mankind, they require payment for the surplus of their crops, of a more substantial description than the exchange of it for commercial bad debts; and should these debts not be provided for, from some other more effectual and more reasonable sources, they must remain unpaid, as they are now, until the end of time. Perhaps on no former occasion, have more strenuous efforts been made to embark the feelings, and the passions, of the operatives, and artisans generally, in favour of the repeal of the corn laws, than have been resorted to on this occasion; but the schoolmaster is certainly abroad amongst them, and these classes know too well their own affairs, and the real foundation of their prosperity, to enter into a conspiracy against their future well being. To reduce the first cost of manufactures at home, intended for exportation, the reduction of the wages of labour is the first thing which is absolutely necessary for the completion of this object. Wages, however, cannot be reduced until the present prices of the necessities of life be previously reduced, which can alone be accomplished by an importation of foreign grain, far larger than the actual consumption requires. The schoolmaster has taught the operatives and artisans of all grades and denominations, to en-

quire into the benefits which they are to receive from an increased foreign trade in manufactured goods, arising solely out of the reduction of their wages, and they cannot discover any advantage to themselves as likely to originate from the circumstance. On the contrary, those who are principally employed in the manufacture of the various articles, which the home consumers require, know full well that their prosperity mainly depends on the state of the home markets, and that by the ruin of agriculture the value of these markets would be so materially depreciated, that the foundation stone on which they at present gain their living, would be for ever removed from under them. One of the delegates of the anti-corn law association, proposed, a few weeks ago, to call out a meeting in Palace Yard, of the working classes, but the steam could not be raised for such an object. They may, to be sure, *call spirits from the vasty deep*, but, the old question may be asked, *will they come?* Not they indeed. They no doubt ought to be obliged to the society, for pointing out to them grievances and complaints which they do not feel, though perhaps they ought to feel them, but for the removal of which, they are not prepared to sacrifice one day's labour, and the wages consequent on its performance. Really the ambition of some of the master manufacturers is as unbounded as is their philanthropy. Since 1816, the consumption of cotton wool has increased four-fold, and yet they remain unsatisfied. They cannot say that population has increased proportionably. Every corner is however searched by them for the discovery of complaints against the present state of society, and the agricultural labourers have received their full share from this fund of compassion. These labourers are generally satisfied with their condition in life, and in many counties they have learned, not without much surprise, that their remuneration is too low. In Essex, where the best qualities of wheat are produced, this is more particularly the case. The wages of agricultural labour throughout the whole of that rich and important county are considered high enough by those who receive them. The best agricultural labourers there receive not less than 15s. per week, and none of them at all conversant with the subject have under 12s., and this too in the neighbourhood of the most populous city in the universe. In addition to these wages nearly the whole of them have a cottage, and a garden, the surplus of the produce of which is sold, for the benefit of these labourers, in the public markets. Since 1830 no complaints have been made by this valuable class of society. There have been no fires and no destruction of property in the rural districts, since that period, and this most fortunate change in their conduct arose solely out of the modification of the corn laws, which was effected by the Duke of Wellington two years before that year. These laws were in 1828 rendered more protective to the general industry of the people, and an almost unbounded quantity of nearly universal prosperity has resulted from this alteration, effected by that administration, of which his Grace was then the head. The violent alteration in the currency had, during

the previous eight years, entailed universal distress throughout the empire, and it was found necessary to protect internal industry, as being the only remedy for the then existing evil. Since then there has not been any general distress amongst any of the productive classes, but on the contrary their condition in life is improved, and their contentment and satisfaction is annually increasing. The capital of farmers embarked in the cultivation of the fields exceeds two hundred and fifty millions sterling, and a seven years' lease is scarcely sufficient for the restoration to them of the property thus employed in field tillage. We say nothing of the landlord's property in the farms, which amounts to two or three thousand millions sterling; but surely this mighty interest is not to be, on slight grounds, interfered with? Property of this immense amount is not to be sacrificed to theory, nor is agriculture to be put in jeopardy, even should the placing of larger sums of money in the hands of the master manufacturers, than they now possess, be the consequence. The proprietors of the national debt, the capital of the farmers invested in tillage, the value of the land itself, the wages of the agricultural labourer, and those of the operative manufacturers themselves, are certainly far more valuable to the empire in general, than the profit to be derived from the clothing of the labourers in the fields of Germany can by any possibility be. With the exception of very few indeed, the manufacturing, and generally the commercial classes, are perfectly satisfied with things as they at present exist. The state of society is so artificial, that the different interests, of which it is composed, are mainly depending on each other for support. The prosperity and the adversity of any member of this arch of society affect the whole body. To reduce the agricultural interest from its just position in the empire, would soon afterwards be attended by the most unfortunate consequences to commerce and to manufactures, more particularly to the operatives in their important departments of industry. The repeal of the corn laws would not only reduce most materially the home consumption of manufactured goods, but it would eventually also increase the number of commercial, mining and manufacturing labourers, by the addition to their body of thousands of families, who, under the present system, receive abundance of productive labour in the fields, but who, should the corn laws be repealed, would be compelled to seek for employment in other quarters at an immense reduction of wages. By a reduction of wages obtained by means of this description, no doubt some of the master manufacturers might, for a few years, increase the consumption of British made goods in the foreign markets; but this source of profit contains within itself materials for its own destruction; for, by the quantity of land which the repeal of the corn laws would throw out of cultivation, and by the very unnatural reduction which the same act would occasion in the wages of labour, provisions of every sort would become so high in their relative value with the means of the consumers to purchase them, that universal misery would, in a few years afterwards, be the certain result of this act of insanity. The school-master, however, has been abroad for years now, amongst artisans and operatives, and to attempt to muster them in Palace-yard, for the adoption of measures, and for passing resolutions destructive to their future prosperity, would be paying a very poor compliment to their intellects,

and to the progress which they have made in every department of practical knowledge. They are perfectly aware that the present favourable appearances in the fields are of far greater importance to their future prosperity, than any meeting in Palace-yard can be, and it is a very fortunate circumstance that, since our June publication, the weather has continued to be as auspicious to the growing crops of every description as it possibly could have been, and there exists the greatest probability of the harvest proving a much more abundant one than we have enjoyed for several years past. The prospects of the wheat crop are as favourable as they can be, nor can they now be altered by anything short of a wet reaping season, which will commence in the third week of July, and in every probability will be general before the close of the present month. There are complaints of a partial thinness in the winter sown wheats, in several of the southern districts, and also in Suffolk. In the other three home counties we are warranted in asserting that there exists the greatest probability of a most abundant wheat crop, and in all the wheat districts in England, to the northward and westward, the prospects are equally encouraging;—indeed, agricultural science has made so much progress of late, that the fields have generally the appearance of highly cultivated gardens. The soil is not exhausted, under the modern system of farming, by weeds and useless herbs, nor is the beauty of the country now deformed by similar excrescences. No vegetation is now permitted but that which is necessary to the people, and the idea of utility is associated with the luxuriance itself of this highly cultivated country. In Scotland the wheat crop is also in an equally favourable position, and promises, at the present moment, a most abundant yield. In Ireland even, although agricultural improvements there have not yet had time to make so much progress as they have done in Great Britain, still the fields are filled at present with vegetation, and a more than usually abundant produce may, with considerable confidence, be anticipated. To secure a good and abundant crop during the ensuing harvest will prevent the exportation of money for the payment of foreign grain, and will increase the sums of money embarked in agricultural and commercial improvements at home. When the agricultural interest receives remunerating prices for the produce of the fields, the home markets for commercial and manufacturing property are always proportionably increased, and when the transmissions of money to foreign countries for the purchase of grain is not rendered necessary by the elements, that money will be employed in home improvements, and will afford additional wages to the productive classes. During the last two corn seasons little short of five millions of quarters of grain were paid for, and imported into this country from foreign nations, and no increased exportation of manufactured goods, or of colonial produce, was visible during the same period. It must, therefore, be naturally concluded that the price of this foreign grain was abstracted from the capital of the empire, which must have done very material injury to the productive employment, and consequently to the wages and incomes of the people. The same evils will not occur during, at all events, the next twelve months, should the present corn season close as favourably as it has begun. On the contrary, the wealth of the country will be directed towards its farther improvement, and not expended abroad in making the necessary provisions for a deficient crop. The wheat crop, as we have already stated, has every appearance of abundance,

and superior farming has rendered the spring wheats as favourable in appearance as those sown previous to the turn of the present year. In the barley countries, and more particularly on the sandy and light soils of Norfolk, the genial rains, and the warmth by which they were generally attended, have given to the young barley plants a most luxuriant and healthy appearance, and consequently this article promises great abundance, should it be gathered in good condition. Of oats we are happy to make a report equally favourable, and in no season was the appearance of the potato crop more cheering than it is at present. In Ireland particularly this is the case, and to the inhabitants of that part of the empire this fact is of the greatest importance. There can be no superabundance of population in the United Kingdom so long as land remains uncultivated, for the inhabitants must be far more profitably employed in the tillage of that land than they can be when transported for similar purposes to the colonies. In Ireland the sources for employment of this description are nearly boundless, and capital embarked there in agricultural improvements, under the protection of the corn laws, in a few years must convert wastes into wheat fields, and open a new channel for the comfortable support of even double her present population. Favourable weather during the remainder of the season is now only necessary, we repeat, to the gathering of a rich and plentiful crop; and, should our present expectations on this subject be confirmed, several millions sterling will remain in the country, and will be expended in the profitable employment of the people at home, instead of being remitted to the continent, as it must be, in payment for foreign grain, from whence it will never return, should the trade in foreign corn again this season be rendered, by adverse circumstances, as free as it has been during the last two corn seasons.

The corn markets throughout the United Kingdom, during the month of June, have varied very little from their usual state at the same period of the season in common years. The supplies of wheat naturally have been small, but with the addition of moderate portions of free foreign wheats, they have been rendered in every respect equal to the consumption. In the value of wheat the differences, since our last review, have been of very little consequence. The duty payable on foreign wheat, when entered for home use, had advanced to 18s. 8d. per quarter, but still the holders of bonded wheats entered only a few thousand quarters when the duty was 16s. 8d., and thus shew that they still entertain strong hopes of prices being dearer, before the commencement of the next corn season. As the supply of home grown wheat for the next month or six weeks must from necessity be moderate, the proper application of capital on the part of some of the holders of bonded wheats may, by possibility, produce the desired effect, and cause a considerable reduction in the existing rates of duty, before any considerable portion of the new crop can be brought forward into the market for sale. Still to the British agricultural interest the accomplishment of these expectations on the part of the proprietors and importers of foreign wheat, cannot be of much consequence, should the next harvest be as good as at present it promises to be, for it will enable the farmers to lay up that stock of wheat which in prosperous seasons it has been their custom to do, and thus, when unpropitious weather, in some future season, renders the crop deficient, half a year's consumption at all events will be found in their possession to make good any partial failure in quantity or quality, which may occur under such circumstances. The rapid progress, however,

which agricultural improvement is now making under the moderate protection which the existing corn laws afford to the cultivation of the fields, and in particular to those of Ireland, must, in the space of a very few years, now make the inhabitants of the United Kingdom not only independent of supplies of food produced by foreign nations, but also increase their commerce in the exportation of the surplus of our growth at home to our own colonies, and to other communities, where climate prevents the cultivation of grain generally. Independent of the transformation of waste lands into wheat fields, there is not one acre of land now, however high may be the state of its cultivation, which is not still capable of much more extensive improvement than it has already undergone. The fields which were in tillage fifteen or twenty years ago already yield at least a fifth more produce than they did then, and it is not possible to predict when any limit may be placed to this increasing growth of the necessities of life. Heretofore it has fully kept pace with the increase of population, and eventually it must surpass it. We may therefore be permitted to entertain a well grounded hope, that before long, grain will form an important article in our foreign export trade, and thus add to the means of the capitalist for giving productive labour and fair wages to all classes at home, whatever may be the department of industry in which they employ their time, and to which they devote their talents and attention. During the past month the decline in the value of wheat generally has been about 2s. per qr., and under the present favourable state of the weather we do not think that any very sanguine expectations need be entertained by the holders and importers of foreign wheats, of any material alteration now occurring, unless it be brought about either by some change in the weather, or by some management in the average prices, by which importation is regulated.

The consumption of barley is, at this time of the year, generally much reduced, but the supply of it has been proportionably small; indeed the heavy taxes imposed on the manufacture of this article, are most inimical to its production, for the use of it might be doubled under different circumstances. In the spirits manufactured at home for instance, a considerable increase in the consumption of home grown barley would be the consequence of the suppression of the trade of the smuggler of foreign spirits; but this change can only be effected by a reduction of the duty now payable on distillation in England. In the United Kingdom the quantity of duty paid home made spirits is at present confined to 24 millions of gallons: of this quantity the Irish use 10½ millions of gallons, with a population of 8 millions in all. In Scotland the consumption amongst less than three millions of people, amounts to little under four millions of gallons; whereas in England, with sixteen millions of people, the quantity of duty paid home made spirits is limited to less than ten millions of gallons. Now in England the actual consumption of spirits is more than double of the quantity on which duty is actually paid, and a profitable field is thus opened to the undertakings of the foreign smuggler, occasioned, not by the superiority of foreign spirits over those of our home manufacturer, but by the intolerable weight of the duty which is charged on them. It has often been our fate to assert that taxation over done destroys the intentions of those who impose it, and that this is decidedly the case requires no greater proof than can be obtained by comparing the quantity of home made spirits used in Scotland and Ireland, where the duties are moderate, with that used in England, where the public charge is excessive. In the article

of malt the barley growers are still more seriously injured and oppressed, for the reduction of the malt duty to one-half of the present charge, would do more than double the quantity of beer at present consumed, and would open an additional market for the consumption of at least five millions of quarters of barley more than can be used under the existing system. The landed interest is sacrificed to taxation, but unless the barley growers complain of the injury done to them by the heavy manner in which barley is taxed, they must go without redress, and the people must continue to be limited in their consumption of beer to at least half the quantity, which, under different circumstances, they would be able to acquire. One million of acres of light soils might be brought forward into cultivation for the production of this additional quantity of barley, and as many pounds sterling would thus be added to the annual income of the land proprietor; the great body of the people would have a large increase to their present consumption of beer, and a farther channel for the productive employment of agricultural labourers would be opened to them; the revenue itself being increased by the alteration, and the immoral occupation of the smuggler being entirely suppressed. The value of barley during the month has been fairly supported, nor is any material decline in it probable until the new crop is brought forward into the different large markets of consumption.

The advance in the value of oats, which was expected to have occurred before this time, has not yet taken place, nor is it probable now that it will do so to the extent which was anticipated when our last number went to press. The supplies from Ireland in particular, have exceeded the general expectation, and from Scotland the arrivals have been much more liberal than a few weeks ago could have been supposed. The home supplies therefore, added to the foreign importations, have equalled the usual consumption, and prices consequently have remained during June without any material alteration occurring in them. To the consequences of the corn laws in Ireland we have been chiefly indebted for the steady state of the oat trade during the last two or three years, and if they conferred no other advantage than this one on the community, their repeal would be an extraordinary act of self injury, and certainly is not required by any visible increase in the exportation of goods to any of the foreign corn districts for the benefit of those who manufacture them. On the contrary, the foreign oats consumed here during that period, have been paid for by specie remittances, and not by manufactured goods; and had that money been paid to British and Irish oat growers, it would now be in circulation at home, employing the people and increasing their wages, as is universally the case when our home crops are equal to the home consumption.

Peas and beans of home growth have continued to maintain rather high prices, but the supplies of them generally have not been equal to the consumption, and some quantity of foreign have consequently been requisite to supply the deficiency. The season for them is now however, drawing to its close, and well grounded expectations are entertained that our home growth, the next year, will be equal to all our wants, and no further expense will be required for the payment of foreign supplies of these articles. Potatoes likewise have continued of the best quality to the close, a great proof of the progress making in the science of agricultural tillage, and which must continue to be attended by the most important consequences to the population, so long as proper

protection is extended to the cultivators of this most necessary root.

The information received during the last month from all the export corn markets in foreign communities, has not been interesting, the purchasers of agricultural produce continuing the old practice of regulating their transactions by the advices which they receive from Mark Lane. Throughout the different ports in the United States of America, during the month of May and the early part of June, an unusual degree of dullness prevailed, nor was it possible to effect sales either of wheat or flour for exportation to any great extent. Complaints, consequently, against our regulations, were on the increase, and the preference which our laws afford to our home producers of grain over those of the United States, was of course blamed, we may say by the entire population, for they feel themselves deprived of no inconsiderable amount of British money, which, under different regulations in our corn markets, they would have received in exchange for the surplus of their wheat crop, and which, in every probability, would have been employed in extending the American manufactures in opposition to our own. This money is far more profitably employed at home in commercial and agricultural improvements. From the Black Sea, and all quarters in the Mediterranean sea, the information latterly received is of the same description. No animation existed in the corn trade in any of them, and prices were generally on the decline. From the Baltic, and from all the corn ports without that sea, the advices received are of an equally gloomy description, although a decline in prices had brought forth some speculators, who had made considerable purchases, particularly in Hamburg and Dantzic, chiefly for British account. A quantity therefore will yet be imported, and probably bonded here, for the prices generally paid will not admit of favourable sales here even at our present quotations. Of the growing crops abroad, the reports are as favourable as they well can be, nor have we heard of any complaints any where on this subject.

WOOL MARKETS.

BRITISH.

JUNE 22.—Such a total cessation of business as has taken place this last week, has scarcely been experienced in the worst of times. All sorts are involved in the same

predicament. The countenances of holders of wool depict the state of the trade most dolefully, and no cheering future prospects are in the least degree apparent to alter them.

	s.	d.	s.	d.
Down Teggs	1	2½	1	3½
Half-bred Hogs	1	2	1	3

Blanket Wool	0	6	0	8
Skin, Combing	0	10	1	1½

LIVERPOOL, June 20.

SCOTCH.—We have again to report a very limited demand for laid Highland wool for the week at our former quotations; the manufacturers buy but sparingly, expecting that as there is no very immediate prospect of improvement in trade, that prices must still decline. There is scarcely any demand for either crossed or Cheviot, but in the absence of any transactions we keep our quotations as before.

	s.	d.	s.	d.
Laid Highland Wool, per 24 lbs. ..	8	0	8	6
White do. (none)	00	0	00	0
Laid Crossed do. unwashed ..	9	0	9	3
Do. washed do.	9	6	10	3
Do. Cheviot unwashed do.	9	6	11	0
Do. washed do.	13	6	16	6
Cheviot white	24	0	26	0

FOREIGN.—We have had a very dull business this week, and only a small quantity of foreign wool changed hands, although prices were somewhat lower. The rates paid at the auction in London were considered to be under those previously realized by private contract. Arrived this week, 893; previously, this year, 29,812; total, 30,705 bags.

FOREIGN.

JUNE 22.—At last week's public sales a considerable falling off was apparent in the demand for most of the wools offered for public competition, and the prices declined from 1d. to 2d. per lb., in consequence of which large quantities were bought in. By private contract, next to nothing is doing, while the imports continue moderate.

POTATO MARKET.

SOUTHWARK WATER-SIDE, JUNE 22.

During the past week the arrivals of Potatoes to the port of London have been as follows:—viz., from Yorkshire, 186 tons; Scotland, 231; Kent, 50; the total being 561 tons. The above being fresh samples, and coming to market in good condition, has caused the demand to be equal to the supply, consequently no difficulty is experienced in effecting sales at the annexed quotations.

PRESENT PRICES ARE AS ANNEXED:—

York Reds, 120s. per ton; Scotch do., 100s. to 110s.; Devons, 100s. to 110s.; Kent Kidneys, 100s.; Kent Whites, 90s.

MANURES.

Subjoined are the present prices of several sorts of manure:—

Bone-dust, 21s. per qr. of 8 bushels.	
Half-inch ditto, 20s. per qr. do.	
Rape-dust, 6l. 15s. per ton.	
Rags, 4l. to 4l. 10s. per ton.	
Graves, 5l. to 5l. 10s. per ton.	
Gypsum, 38s. per ton.	
Salt, 2l. 5s. dirty, 2l. 15s. clean, per ton.	
Carbon, 12s. 6d. per qr.	
Soap ashes, 10s. per ton.	
Artificial Manure, 12s. per qr.	
Poittevin's Patent Disinfected Manure, 13s. 6d. per qr.	
Nitrate of Soda, per cwt.—19s. 0d. to 19s. 6d.	
Nitrate of Potash or Saltpetre, 24s. to 27s. per cwt.

THE FARMER'S MAGAZINE.

AUGUST, 1840.

No. 2.—VOL. II.]

[SECOND SERIES.

PLATE I.

The subject of the first Plate is Nimrod, the property of Mr. Lacy, of Pantton, near Louth. This horse was bought by Sir David Baird, at Callender, near Falkirk, in Scotland. He was hunted for seven seasons in England by that gentleman, one of the hardest riders in the kingdom, and performed during that time, more than the work of two horses, without being sick or lame. The prize of Ten Sovereigns, as the best horse for getting hunters, was awarded to him at the Louth Agricultural Meeting in August, 1839; as also the premium of Seven Sovereigns, at the Lincoln Meeting in August, 1839, and a premium of Five Sovereigns as the best horse for getting hacks.

PLATE II.

“LITTLE WONDER,” WINNER OF THE DERBY.

(For Description see page 146.)

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

Although a difference of opinion may exist as to the *amount* of advantage which the agriculture of Scotland has derived from the Highland Agricultural Society, nevertheless it is conceded by all, that its effects have been beneficial. Experience, therefore, confirmed by the support of a numerous and influential body of landowners and occupiers leads to the conclusion that the Royal Agricultural Society of England will be the means of effecting such an improvement in the cultivation of the soil of this country, as will enable the growers of agricultural produce, to meet the demands of the population, to an extent so ably described by the celebrated Watson, Bishop of Llandaff, “If the time had finally come, when an unproductive acre of land could not be found in either of these, our fortunate islands, we shall then have food within ourselves for the annual subsistence of, at least, thirty millions of people; and with a population of thirty millions, *what power in Europe, or what combination of powers, will dare attempt our sub-* OLD SERIES.]

jugation.” Whatever may be expected from influence and talent, may be predicated from the demonstration made at the second meeting of the Royal Agricultural Society of England, at Cambridge, in the past week. Patronized by the Sovereign of this great empire, supported by a Prince of the Royal Family, aided by the name and influence of the greatest living warrior, upheld by the most influential landowners of the United Kingdom, and counselled by the advice of the most intelligent and experienced *practical* farmers, it will not be matter of surprise, that every person who is a member of such a society should feel proud of his connection with it.

If then the highest, the most renowned and respected amongst the nobility, the first commoners in the land, nay, those who have filled some of the highest offices in the state, felt a pride in boasting at the late meeting at Cambridge, of their having been the first to announce it in public, of having been present at its birth, those who move in an humbler sphere, like ourselves, may be pardoned the vanity of taking credit for having suggested the establishment of that society, for having advocated it when those who now seeing its suc-

G

[No. 2.—VOL. XIII.]

cess, proffer their aid, withheld their support, nay, even opposed it.

We seek not to array ourselves in borrowed plumes, we desire not to detract one jot from the merit of others, we ask only that poor, but proud reward, an acknowledgement of the good which we have been instrumental in effecting. To the early readers of our journal, these remarks would be unnecessary, but as there are very many who have not had the opportunity of witnessing the course which we have pursued on this subject, we deem it necessary to go into some detail, sincerely hoping it may not be tedious, but relying on the importance of the subject as an apology. The pressure of other matters will not permit us to go minutely into the matter at the present moment, but we recollect, that so far back as the year 1834, we set forth the advantages of the Highland Agricultural Society, and invited the co-operation of the parties interested to establish a similar institution in England. The following is an extract from an article in the *Mark Lane Express* in that year:—

“The only means by which there is any hope of accomplishing an improved system, is by the formation of a CENTRAL LANDED INTEREST SOCIETY for Great Britain and Ireland, and we are happy to inform our readers that there is now every reason to believe that the Society will be finally organized at an early period of the ensuing session.

“In inviting the co-operation of the landed interest & agricultural societies to this object, we may remind them that the purpose of the Society now forming is to increase the present wealth of the country by the removal of artificial as well as natural obstructions, and by a more extensive application of the sciences to the cultivation of the soil. That constituted upon similar principles to the HIGHLAND SOCIETY, it will be conducted by directors, annually to be chosen from the more eminent of its members, who shall be subdivided into committees for the various sciences applicable to husbandry, and for rural economy. That its funds will go to provide a convenient building, to contain a library, museum, hall, &c. where meetings to hear reports, lectures, essays, &c. will be held periodically,—to correspond with foreign societies, and form a centre of communication for those at home;—to give premiums for inventions of national utility, and to promote the establishment of schools throughout the country, for the instruction of farmers' sons in the sciences applicable to agriculture.”

“We earnestly trust, therefore, that a METROPOLITAN SOCIETY for this object will meet with the cordial and unanimous support of all interested in the advancement of the interests connected with the soil, and that it shall not be much longer said, that amongst the innumerable institutions now existing in London, there is none specially devoted to the improvement of agriculture, the first and greatest concern of the nation, and the foundation of its prosperity in every other matter.”

Omitting many intermediate occasions on which we drew attention to the subject, again in 1835 we urged the formation of a society to be called “THE ROYAL AGRICULTURAL SOCIETY,” a title now adopted by our society, and we then laid great stress on the importance of *excluding politics*. At that period some parties, desirous of establishing a Central agricultural society, came forward

with a goodly array of influential names, and entertaining a hope that the object we had so long desired would at length be entertained, we lent them our assistance, until from certain circumstances our apprehensions were aroused to the probability that the alloy of *politics* would be found in the materials of which the society was composed, when we warned them of the consequences in the following terms:—

“It will be seen by an advertisement in another part of our paper, that a meeting will be held at the Freemason's Tavern, on Tuesday, the 15th inst., to take further steps for the formation of a Central Agricultural Society in the Metropolis. The period is very opportune, as many of the most leading agriculturists in the kingdom will be in London, on the occasion of the meeting of the Smithfield Club. We feel considerable anxiety as to the result of the meeting, being satisfied that it will wholly depend upon the known sentiments of those individuals who may be induced to take a prominent part in the proceedings of the day. Many gentlemen who have great claims on the agricultural body for the zeal displayed in their cause generally, as well as for their exertions in establishing a Central Agricultural Society, are well known not only to entertain at this moment strong opinions on the currency question, but to have constantly inculcated their opinions through the medium of the press, and by their speeches at public meetings. Now we do not hesitate to give it as our opinion that unless it be openly and honestly avowed that no intention of interfering with the currency exists in the bosoms of those who will be called upon to take a leading part in the future proceedings of the Central Society, the attempt to establish it will be an abortion.”

That Society was *formed* but not *established*. The managers persisted in entertaining political questions, and in 1836 we again adverted to the society in the following language:—

“Long previous to the formation of the Central Agricultural Society we strongly recommended the establishment of such a Society. We pointed out as our model, the Highland Society, and we expressed an opinion, which we still maintain, that with all the advantages which might be derived from the experience of that Society, an Association might have been formed in the metropolis, which would have conferred incalculable benefit upon the agriculturists of the United Kingdom. Some gentlemen who were desirous of establishing such an Association, communicated with us, and we aided them in their endeavours till we found, that the course they were about to pursue in the establishment of the Society was one, which, from the subjects prominently put forward, and the party character the body was likely to assume, could only bring the cause of Agriculture into disrepute and ridicule. We pointed out from time to time the prejudicial consequences which must result from the line of conduct pursued by the leading members of the Society, and we pronounced the Society to be deeply imbued with a political spirit which must prove fatal to its utility. Our remarks called forth from the organ of the Society the most bitter observations, and subjected us to the most unfounded calumnies and falsehoods. Firm to our purpose, and anxious to promote substantially and permanently the cause of agriculture, we continued to express our opinions despite the misrepresenta-

RANSOME,

(page 133.)

Barrow Turnip Cutter.

tion to which we were exposed. We over and over again declared that the Society as constituted would not advance the interests of the *tenantry*. We pronounced the Society to be a political body, which assertion was strenuously denied under the authority of the leading members of the Society itself, but we had formed our opinion from the character of the leading members of the body, and from the tenor of their speeches at the different meetings of the Society, and we were not to be shaken."

We continued our remarks in these terms:—"TENANT FARMERS, we tell you now, as we have often told you before, the Central Society, whilst composed of its present materials never will benefit you one single tittle." Mark the result; the Central Society gradually dwindled away, and has ceased to exist. Undaunted by the establishment of that society which retarded the attainment of the object we desired, namely, the establishment of a society *wholly free from politics*, we persevered in advocating the adoption of our plan, both by private communication with individuals, and by publicly addressing the agricultural class; and well do we remember an observation of Mr. Bennett, the member for Wiltshire, made to us in the lobby of the House of Commons, when addressing him on the subject, "you will never succeed, everybody is disgusted with the Central Society." At various times we kept the subject before the agricultural body, and in August, 1837, we observed, in the course of an article in this Journal, "During the few weeks that her present Majesty has occupied the throne of these realms, she has manifested an ardent desire to promote the prosperity of the nation and the happiness of the people. There is no one act which would tend so much to bind close to her the hearts of the sturdy British yeomanry as the manifestation of her desire to promote improvements in the pursuit in which they are engaged. As the re-establishment of a board of agriculture upon an *improved plan*—the collection and diffusion of agricultural knowledge throughout the kingdom—the connection of approved local practices upon various matters, and the institution of accurate experiments would be productive of great and immediate good results."

Again, in October of the same year, we used the following language:—

"We have uniformly urged the rejection of politics at agricultural meetings, and daily observation tends to confirm us in the opinion, that nothing but schism, disunion, and ultimate annihilation, can be the result of an opposite course of proceeding."

In December of that year, at the meeting of the Smithfield Club, we took the liberty of communicating with Earl Spencer personally upon the subject, and in which we were aided by Mr. Clarke Hillyard. His Lordship conferred with his Grace the Duke of Richmond, and it was arranged that the subject should be introduced at the dinner of the Smithfield Club. The manner in which the announcement was received, is well known to our readers. From that moment to the meeting in May, 1838, when the Society was established, we left no means untried to obtain supporters. Mr. Handley was also incessant in his exertions, and the result has been the glorious and

triumphant meeting at Cambridge last week. It should be especially noticed, that for the five years during which we advocated the formation of the Society, before its establishment, and for *some time afterwards*, those journals which boast their attachment to the farmers, who call themselves *par excellence*, the "farmers' friends," would never admit a line into their columns in furtherance of it. The "Mark Lane Express," and the "Farmer's Magazine" were the only agricultural publications in which the benefits of such a society to the agricultural class were advocated. We have now given a very imperfect outline of the part which we took in the establishment of a society of which we confess to be proud, and we trust it will not be deemed an improper degree of vanity, to be desirous of placing ourselves in our proper position before our agricultural friends, leaving it to them to assign to us such credit as, in their opinion, we may merit. *Mark Lane Express.*

ON SWINE.

[This article is extracted from an American publication. We have given cuts of all the animals in order to carry out the object of the writer in contrasting the *well* and *ill* shapen:—ED. F.M.]

The writer of the following article, having become a breeder of improved swine to some extent, among other choice stock, has found himself so often called upon for descriptions of them, and rules for their breeding, that, by way of general answer to numerous inquiries, he has embodied below such information as his little experience and limited range of inquiry have enabled him to obtain. Though much has been desultorily written upon this interesting subject, we have still to regret the want of some standard work to refer to, for full and complete information in so important a branch of rural economy. It is to be hoped, however, that the British Society for the Diffusion of Useful Knowledge will soon add to the valuable Treatises that have recently appeared on horses, cattle, and sheep, a similar one on swine, and thus supply this great desideratum. The substance of the rules of breeding, together with some other observations, appeared originally over the writer's signature, in the 2nd and 3rd numbers of the current volume of that excellent agricultural periodical, the *Franklin Farmer*, published in Kentucky. These who then took the trouble of perusing them, he trusts will excuse their re-appearance here, among a numerous and almost entire new class of readers.

Of the hog tribe (*Sus*), zoologists describe no less than six species, some of which are so entirely distinct in their general habits and appearance as to have prevented their ever breeding, or even associating together. Five of these species, however, can only be regarded as matters of curiosity to us at present; we shall therefore pass them over, and come at once to that known as *Sus scrofa ferus*, the common wild hog of the Eastern Continent, and from which has directly descended the domestic among us, in all its countless varieties. Except with those nations where its flesh was forbidden by their law-givers, the wild boar has ever been considered a great delicacy, and eagerly sought for, not only to gratify the

appetite of the epicure, but as affording a favourite amusement in the chase, that was considered equally noble, dangerous, and exciting to those who followed it. Among the earliest feats that Zenophon thinks worthy to record of his favourite hero Cyrus, is that of hunting and slaying the wild boar with his own hand; and the greatest of modern heroes, Napoleon, thought a chase of the same kind highly indispensable to royal habits, and to assist in qualifying him to assume the imperial purple, with the greater dignity and grace.

The time of the domestication of the hog, like that of most other animals, is lost in remote antiquity, but that it must have been very early we infer from the fact, that the Greeks and Romans offered it as a grateful sacrifice to Ceres, the goddess of agriculture, in order to propitiate her smiles upon their labours, previously to commencing their harvests. That distinguished philosopher Aristotle, also gave hints on the raising and breeding of swine, which are worthy of regard at the present day; and Varro and Columella, if we would substitute soft, thin hair for "thick, strong, and erect bristles," have described the main points of what we may now consider, with all our modern improvements, a very perfect hog.

The reasons that were supposed to influence the forbidding of eating swine's flesh, as well as that of several other creatures, under the Levitical law, are, that the children of Israel, at the time of their exodus out of Egypt, were a very debased and gross people; but few grains and vegetables were then cultivated to vary the food of man, and as they were destined to inhabit where a generally hot and dry climate prevailed, a great indulgence in these meats would tend to thicken the blood, check perspiration, and, consequently, especially engender scrofulous, scorbutic, and cutaneous diseases. We find among the Egyptians, that some of the same prohibitions of Moses were made sacred by their priests to that singular people, with the intention, undoubtedly, of more certainly preventing their being used as food, and mainly for the reasons spoken of as above. Pork, however, as now usually made, and above all eaten in the moderate quantities that it generally is, and accompanied by so great a variety of grain and vegetable food, can no longer be considered objectional, especially in a cool climate; and as it is one of the most palatable and substantial of meats, the cheapest and easiest reared, the longest and most certain to keep, it has at length become the most necessary item of the stronger food of civilized man, and without doubt the most important of the stock-grower's products in the United States.

What amount of pork is annually raised and consumed in the republic, it is impossible to accurately say, but something of an approximation may be made towards a calculation of it. The census of the present year will doubtless give us a population in round numbers of 16,000,000. The army ration to each soldier of the best quality of mess pork per day, is three-fourths of a pound, which would be about equivalent to one pound of the whole hog. It is intended that this ration shall be rather more, upon an average, than each soldier can consume; we will therefore put the allowance in whole hog pork at twelve ounces. Admit, for the people at large, that beef, mutton, fish, &c., would make half their meat, again deduct half of this remainder for women and children not being as great consumers as men, and the result would be three ounces per day, or say sixty-four pounds each per annum for the whole population of the United States. But for fear of an over estimate, we will suppose the consumption only two

ounces per day—this amounts to 730 million pounds, or 3,650,000 barrels, which at eight dollars per barrel, (the probable average price, taking one year with another) would make 29,200,000 dollars as the value of our pork consumption alone. Now many of our most experienced stock-growers assert, that the improved races of swine will make three times as much meat from the same quantity of food, that those of the unimproved will; and again, the quality of the meat is so much superior that it will go twice as far in giving vigour and sustaining life. Experience has convinced me of the truth of these assertions; but lest we should claim too much, we will allow only one-half saved, or say, in round numbers, fifteen millions of dollars. What a vast sum to be annually lost to America, just for want of a little attention in breeding pigs! Why, if properly applied, it would soon finish all our projected rail-roads and canals, or keep a good school one-half of the year in every district in the Union.

Of all the known varieties of the domesticated hog, the Chinese has long been celebrated as decidedly the most perfect in shape and general conformation. How this breed was first produced, it is impossible now to say; there is no doubt, however, in my mind, but that, like the Arabian horse, it was *original*, and that the best specimens to be found on the Eastern Continent, are the identical counterparts of the pair that descended with Noah from the ark, after the subsiding of the Deluge, and that all the other varieties deteriorated by running wild or from carelessness in feeding, and neglect and inattention in properly breeding—the goodness of the Deity never forming in the beginning the detestable brute that we see roaming in every direction the country round, like a veritable cannibal, seeking who and what he may devour. Be this as it may, the Chinese, as we find them scattered along the coasts of the Celestial Empire, and on the adjacent islands, vary greatly in size, and somewhat in shape, and are of every shade of colour, from pure white up to jet black. The most approved varieties, however, may be thus described. A fine head and snout, with the face somewhat dished, small soft upright ears, a snug and very thick deep carcass, large hams and shoulders, short legs, delicate feet, soft thin hair and skin, a tendency to grow and fatten almost upon air alone, and to give, when slaughtered, very little offal, and the sweetest and most delicate of pork.

Below are the portraits of a pair of the improved Chinese (figs. 2 and 3,) in the writer's possession, bred by himself, and faithfully sketched after the originals, by his friend Mr. Julius Gerber, and engraved by Mr. J. W. Orr. They are represented in no better flesh than they will always attain when full grown running in a common pasture during the summer, or with the most moderate allowance of food in the winter.

[FIG. 2.] MAID OF ERIE.

[FIG. 3.] SENECA CHIEF.

As now bred by the writer, their live weights full grown, are generally from 200 to 300 pounds; occasionally they have gone as high as 400 pounds, but this is extremely rare. They are equally hardy, enduring heat and cold as well as any of the native swine; are fair breeders, usually having from six to nine pigs at a litter; mature easily, and can be fattened at any age. Whether in field or pen, they are ever quiet; the loosest boards keep them up, and the poorest fence secures them within their bounds; and like Diogenes in his tub, they seem never so happy as when left alone to sleep, and dream, and cogitate on deep philosophy. Their meat is exceedingly delicate and sweet. In England it bears the highest price, and is called par excellence the "gentleman's pork." The improved Chinese will give a greater amount of pork for their feed than any other breed in existence; and it is in allusion to this circumstance that the able editor of the *Maine Farmer*, with no less truth than justice, calls them the "poor man's hog." Boars of this breed are highly recommended to cross with the common hog of the country, as they most rapidly improve the quality of the meat of their progeny, fine their points, give breadth and depth to the carcass, quiet their disposition, and add a greater tendency to mature quick, and fatten kindly, and at the same time increase their sizes.

Many attempts have been made in Europe to improve the breed of the native swine, by selections and otherwise; but so far as the writer has been able to follow them up, there has been little success, and that little very slowly obtained, except only where resort has been had immediately to the Chinese boar. This is particularly the case with England, whose efforts seem to have carried her, in this department, as far beyond her neighbours as in that of the improvement of horses, cattle, and sheep. Every country there boasts of its breed of swine, and many are certainly very deserving, having derived their chief excellence from a cross more or less deep with the large white Chinese boar. Of these are the Leicester, the Bedford or Woburn, the Sussex and Cheshire. But the most decided improvement, and which by the care and skill of recent breeders has now nearly attained perfection, was that of the black Siamese boar upon the old stock of Berkshire county. This, I understand, began about forty years since. The

Berkshires were then mostly a long, large, coarse, lop-eared hog, of a sandy or reddish brown, or white, with black spots, and coming up, not unfrequently, to the high weights of 800, and even 1,000 pounds. But it was a slow feeder, long attaining to maturity, an enormous consumer, and in common with most of England's other varieties, an unprofitable beast. Yet possessing rather thicker hams and shoulders than the other kinds, a longer, fuller body, and its meat abounding greatly in lean, the little, short, fat, black mouse-eared Siamese told well in the cross; and thus was produced the dark, splendid Berkshire, that at present occupies the same rank among hogs that the Durbams do among cattle. They mature quickly, and like the Chinese, can be fattened at any age, and still may be selected, when desirable, for great sizes are prolific breeders and the best of nurses; thrifty, hardy, and of most excellent constitution. They are fine in their points, possessing remarkable thickness in the ham and shoulder, and show a round smooth barrel of good length, that gives a large proportion of side pork. They have little offal, thin rind and hair, and few or no bristles.

As now bred, the Berkshires vary somewhat in size, appearance, and maturity. Those with the finest heads, dished face, and rather upright than forward ears, with a snugger shoulder and ham, and shorter body, most resemble the Siamese ancestor, and therefore are quickest to mature, and probably give the most delicate meat, and to one satisfied with moderate size, are undoubtedly to be preferred. Barrows of this description, if well fed till 18 months old, easily attain 300 to 400 pounds, and weights within these limits are the most eagerly sought for at the Smithfield market, and are probably on the whole the most profitable for both consumer and producer. Others, generally of a strait nose, with a coarser head, and ears protruding well forward over the eye, or slightly lopped, with greater length of body, incline more to the original Berkshires, attain higher weights, and require a longer time to mature. There are individuals, however, occasionally possessing all the fine requisites of the former selections, together with the large size of the latter. Of this class the subjoined figures are supposed to be as fine specimens as any at present in the United States. (figs. 4 and 5.)

[FIG. 4.]—RAVEN HAIR.

[FIG. 5.]—BLACK WARRIOR.

This pair is among the writer's breeding stock, and he believes that he can confidently appeal to the numerous gentlemen who have favoured his piggery with a call, to attest to the faithfulness of the portraits. They are not considered fat at all for Berkshires, but merely in good store order, and were two years old last spring. The live weight of the sow is now about 450 pounds, that of the boar 500 pounds. They have never been pushed at all in their feed, but kept steadily along, and when grown, in fair condition will weigh respectively 600 and 700 pounds at least, and probably something more.

We now come to a pair of fatting barrows of the unimproved breeds of swine. They abound throughout the country, under a variety of most euphonious names, but we may suppose those of Alligator and Landpike about as appropriate to them as any others that could well be applied. They are not, however, introduced here for derision, or for the purpose of getting up a caricature, as the originals can easily be found; but to show that there is *something in breed*, and to illustrate the difference between a good animal and a poor one of the same variety. They have long, peaked snouts, coarse heads, thin chests

[FIG. 6.]—ALLIGATOR.

[FIG. 7.]—LANDPIKE.

and narrow shoulders, sharp backs, slab sides, steep rumps, and meagre diminutive hams, big legs, clumped feet, with the hide of a rhinoceros, and the hair and bristles of a porcupine, and as thick and shaggy as a bear's. How can such animals thrive, and above all, ever be fattened? To attempt to make them do either, as the writer found to his cost in his first efforts at farming, were time, and money, and produce thrown away. They have no capacity at digestion, and concocting their food in the stomach for nourishment; and if they had, to the formation of what would it all go? Pork? No, indeed—but offal, bones, rind, bristles and hair, with a narrow streak of gristle underneath, and a still narrower line of lean, both as tough and rank as

whitleather, and about as incapable of being masticated; and if it were not, must require a vast deal of larding to make it sustain human life. I have been obliged to purchase it occasionally for my workmen, and before they could possibly get up a fry for breakfast, twice the weight in lard from other hogs had to be added to it; and as for baking or boiling, one might as well undertake to stew an alligator's hide itself. In disposition they are like the Ishmaelites of old—their snouts are against every man, and every man's hand is against them. No reasonable fence can stop them, but ever restive and uneasy, they rove about seeking plunder; squalling, grunting, rooting, pawing, always in mischief, and always destroying. Enormous gor-

mardizers, yet never satisfied; but like Pharaoh's lean kine, they lick their jaws for mere, and show in their miserable carcasses no return for the food consumed. In short, the more a man possesses of such stock, the worse he is off, and he had far better sell his produce at any price—yes, even his corn at a dime a bushel, than to put it into such totally worthless brutes.

OF THE CHOICE OF STOCK, BREEDING, AND REARING.

THE BOAR.—After obtaining as many other good points as possible in choosing a boar, reference should then be had to a strong, masculine appearance in him, even at the risk of getting some little coarseness, as this denotes great vigour and constitution. Both sexes of the improved breeds of swine are, if allowed, precocious in breeding. To prevent this, the boar pig must be separated from the sows, as soon at least as he has attained four months of age, and it is better thenceforward to keep him entirely by himself. For this purpose, a close covered, roomy, pen, with a plank floor, and plenty of litter, is provided for him to feed and sleep in, and retire to whenever he pleases, and made comfortably warm in winter, and cool in summer. This communicates, by a door that can be opened and shut at pleasure, with a yard for him to root and exercise in, and a strong upright post or two to rub and scratch against, and a slough hole to cool and refresh himself by wallowing at his pleasure during hot weather. If this yard could be extended to a good grass pasture, with clear, sweet water passing through, it would be still better for the boar to have a run there, and more conducive to his health, vigour and longevity.

He should never be permitted to be used till seven months old at least, and it would be much better that he were allowed to run till nine months. But if commencing at seven months, he should cover sparingly, say not more than fifteen to twenty sows, till a year old, and these as distant apart as possible, not more than three in any single week. From this time, till he has pretty full vigour, which for the Chinese I should call twelve, and the Berkshire at eighteen months of age, he may be used a little more freely. His spring seasons might then vary from twenty to thirty sows, and the fall nearly double this number. The sow should be introduced to him just at the close of her heat, and allowed but one coitus, or two at the most, and then be immediately taken away. It has generally been noted, that one covering produces a greater number, and stronger offspring, than two or three, and that an *ad libitum* service is alike pernicious to all parties.

During his seasons, if pretty freely used, he should be kept up, and with care, being fed at least three times a day, about, or quite as much as he will eat. The best aliment for him then is boiled or soaked corn, with plenty of pure fresh water, and for variety some swill from the house, slightly thickened with meal, (oat is the best,) and a few raw or boiled vegetable roots. As an antidote to disease, and to give tone to the appetite and assist digestion, a table spoonful of sulphur is occasionally put in his food; salt also is placed where he can get at it when he pleases, and charcoal or small chunks of rotten wood, together with a handful of crushed bones. Between the seasons his feed is made lighter, but sufficiently nutritious to keep him in fair store order, and more exercise, and a greater run, as above, is recommended. A

good animal thus treated may last ten years or more, and get excellent stock from first to last. I have lately heard of boars having been effective till past twenty, and can see no good reason to doubt the truth of the communication, as the hog has been known both in ancient and modern times, to have frequently attained the age of thirty years. The duration of their services, and goodness of their stock, depends mainly upon their treatment. Great error is committed in irregularity of feeding, and overtasking their procreative powers, and hence the frequent disappointments in distinguishing animals, not producing stock at all equal to themselves.

THE SOW.—When growing pigs or shoats, and kept up in pens, not more than half a dozen sows ought to be together, yet in large pastures any reasonable number may be suffered to associate. But when full grown, and especially if of a large size, two at most is sufficient together in confinement, and it would be still better that each one had an apartment to itself in the piggery. Unless the pig was lean, and the object was to somewhat fatten her, it ought not to be allowed to breed, if a Chinese, till twelve, and if a Berkshire, till eighteen months; and if something extra large was wanted, defer their coming in still six months longer. There is then no check in growth, and the first litter of pigs is usually as fine and as large as any subsequent ones. The period of their gestation is sixteen weeks, and the time that they are stinted to the boar should be set down, and one month at least previous to farrowing, each sow should be taken up and occupy a place alone, either in pasture or in pen, similar to that described for the boar, be kept in good order, and strictly watched when expected to bring forth. As soon as dropped, see that the pigs are cleaned and take the teat, and the dam rid of the placenta, and that carried off and buried. She should then be supplied with short cut litter in a moderate quantity, so that her young will not get tangled in it, and be smothered. Oat straw is the best for this purpose, wheat and barley having bearded heads, which if eaten frequently, hook to the intestines, and cause a dangerous irritation and often death. The watching should continue several days, till the pigs are strong and lively, especially if the sow be full grown and heavy, otherwise they are in danger of being laid and tread upon, and killed. One pig more saved than leaving the sow to herself, amply repays all this extra attention.

The sows being somewhat feverish at farrowing should have what water they please to drink about blood warm, but very little food, and that of a light kind the first twenty-four hours. After this their feed may be gradually strengthened, and when the pigs get a week old, the dam should be fed all it will eat three times a day without cloying. All the whey and milk that can be spared, with a mixture of oat and barley with pea or Indian meal, of one part of either of the latter to three parts of the former, is highly recommended for nursing, together with an equal quantity of boiled or steamed vegetables. As soon as the pigs will eat, a small open box frame should be placed in the pen, under which they could run and be separate from the sows, a trough set there, and milk with a light mixture of meal and cooked vegetable roots, poured out for them. This greatly relieves the sow, and adds much to the growth of the pigs; they wean then without scouring, losing condition in the least, or being checked in their growth.

It is generally thought that pigs do as well to be weaned at six weeks old as later, for the little milk that each then gets is obtained by more or less

quarrelling, and adds a distaste to their other food; besides it is a great consideration to get them off the sow as soon as possible. Eight or ten great pigs tugging at her breast for two or three months, is hard to be borne, and is frequently very pernicious to her teats. In weaning, all but one should be taken off, put the dam on short allowance, and in two days, take the remaining pig away, allowing it at first to draw the breast twice a day, and then diminish till once in two or three days during a week, then turn the sow out to grass and leave off entirely, and commence gradually to put her into condition again. The Berkshires especially are great milkers, and must be well attended to at weaning time, or the breast will fill, become caked and swollen, and finally ulcerate, and be the cause sometimes of the death of the sow. Two litters are allowed per annum, and a preference for farrowing in this climate is given to the months of April and September. Farther south later and earlier will answer. A pig when first dropped is a very tender animal, and if the weather be too cool it will perish; the dam also is likely to become ravenous and devour her offspring, or refuse to nurse it.

After being weaned, pigs should be fed upon cooked food, at least for a few days; they will then very rarely scour, and if they have a dry, warm place to sleep in, covered from the weather, will not take cold or be afflicted with swollen head and throat, that too often destroys them. Night air is very pernicious to young pigs, and is the direct cause of most of the ills that affect them. In order to give them a handsome shape and good growth, some attention must be had to their food and accommodation. To their snug sleeping apartment in the winter, a large dry yard that the sun will shine in when out, should be appended for exercise, and in summer they ought to have the run of a good grass or clover lot, with pure water if possible passing through it. The best food that can then be given them, is as much milk, whey, and house-swall as can be spared, and a mixture of oat and Indian meal about half and half, with flax-seed ground with it, at the rate of a pint or so to the bushel, or for want of this a quart or two of oil meal may be substituted. All this, and more especially if it can be cooked beforehand, mixed with an equal quantity of steamed roots of any kind, such as potatoes, beets, &c., makes the most palatable, healthful and thriving food for young pigs and old, that I know of. There is a very great saving in cooking food for hogs, and making it pretty thin with water; the liquid alone, in this case, seems to go farther with them than the whole of the food uncooked. Repeated experiments have established the fact, that water, under these circumstances, becomes very nutritious. Shorts and bran, so much given to pigs, is most miserable food alone, and especially if used without being cooked. It almost invariably scours them, and under the most favourable circumstances I could never see much thrift from the feeding.—Cold swill, and above all if any frozen, is very pernicious; it is the cause of several diseases, especially that of casting the inwards, and ought never to be fed. When confined, either as store animals or fattening, all hogs should have a little sulphur and salt occasionally in their food, with pure water to drink at all seasons once or twice a day, and charcoal or chunks of rotten wood thrown to them, and be allowed now and then to come to the ground a short time for the purpose of rooting and eating dirt. They may not fat, or rather bloat up, quite so fast for this, but their flesh will be much superior, and the poor animal will be kept free from the fever that

otherwise so much torments it; and indeed, it is relieved, except in rare cases, of all other diseases.

Of the pathology of the hog, the writer acknowledges almost total ignorance; he trusts, however, that some one well qualified will soon be induced to come forward, and treat the subject with the ability that it so highly merits. In so doing, not only the more extensive breeder, but the public at large, would be placed under great obligations, for there are few families in the United States, out of our large cities, that, to use the Irish expression, do not "live neatly and keep their pig."

Buffalo, December, 1839.

A. B. ALLEN.

TO THE EDITOR OF THE FARMER'S MAGAZINE.

Would you be kind, through the medium of your excellent work, to ask of your correspondents some account of a short useful breed of sheep, the Banboroughshire or Banffshire, as I can find no account of them in any work I have met with. Are they originally a distinct breed of long woolled sheep?

Much has lately been said about Italian rye-grass being, or not being, a perennial grass. I have some which has been mowed for four years, and the aftermath eaten with sheep, which is still very luxuriant. I have another field; the first year was mowed and the aftermath eaten with sheep, second year pastured with sheep, third year pastured hard with sheep, and now the sheep being removed for a fortnight, is uncommonly luxuriant. Another field, in which I sowed one bushel of Italian rye grass per acre, upon old sward which formerly was of the most meagre description, has been so much improved by it, as to materially alter the herbage, and what formerly would scarcely afford maintenance for anything, has these last four years been a good rough useful pasture, increasing rather than diminishing in the quantity of roots of the Italian rye-grass. My opinion is, sheep will leave every other description of grass untouched, so long as they can get the succulent stems of this grass, and perhaps injure it by eating it close; but that it is naturally perennial on dry soils I have not the least doubt. My soil is on a strata of magnesian limestone.

I have sowed it along with red clover, white clover, trefoil, and different sorts of rye-grass, rib-grass, timothy-grass, cocksfoot, and the natural grasses which you obtain by sowing hay seeds, but in every instance, I find the Italian eaten first, and young cocksfoot the second.

July 5th.

THE WIRE WORM.

SIR,—Having been a subscriber to your valuable Magazine many years, I shall feel obliged if any of your correspondents would inform me what is the best method to destroy the wire worms. I have a piece of hop ground which is sadly infested with the depredator, and having tried lime, and other nostrums, I don't find any benefit. If any one, therefore, will be pleased to give me advice on the subject, I shall feel greatly obliged. I remain yours most obediently,

J. C.

Kent, 24th July.

ON A NEW METHOD OF FEEDING SHEEP ON TURNIPS.

BY JAMES STEWART MENTEATH, ESQ., YOUNGER,
OF CLOSEBURN.

(From the Quarterly Journal of Agriculture.)

(Concluded from page 36.)

4. That the *manure* of the sheep, fed with such a variety of rich food, will be of much better quality. It is a well known fact, that the better an animal is fed, the more valuable is the manure produced; and by giving oilcake, its fertilizing powers are nearly doubled. No dung is more valuable to the farmer than that of his sheep. It is united with a greater proportion of animal substances, condensed into a smaller compass, than in the dung of almost any other quadruped.

5. That it is one signal advantage in this management of turnips, that if any part of the field be poorer in its soil than other parts, it may be made equally rich and productive in bearing crops of grain and grass with the richer portions of the land. In feeding the sheep with cut turnips, they may be made to stand as long as it is wished on any particular part, and by judiciously removing the troughs to different parts within the fold, the manure may be equally well distributed all over it. There can be no more effectual plan than this of improving poor, sandy, gravelly soils. The flock confined within the fold, tread and render the earth more compact and retentive of moisture, and by their droppings, urine, and perhaps perspirable matters exuded from the fleeces while lying on the ground, make it fitter to yield heavier and richer crops of grass and grain.

6. That the *carcass* of the sheep is not the only part of the animal which is improved by this new method of feeding. The *wool*, which is an object of great value at the present time, is produced in greater quantity, and of better quality. The more improved higher condition of the sheep, influences the quantity and quality of the fleece.

"It ought never to be forgotten, that the growth of the wool is liable to be materially affected by the system of feeding pursued. It is essential to the evenness and strength of the staple, that the feeding of the animal should be uniform, without any sudden interruption or transition. Where this is suffered to take place, the natural progress of the wool is for a while most injuriously interfered with. It continues to grow, but the new fibre is unhealthy, and becomes so weak as to snap under the operations of the manufacturer. Much wool is injured in this way by the change between summer and winter keep; and sudden transition from rich to poor, and from poor to rich feeding, ought most carefully to be avoided."

The merino wool in Saxony, though a much colder climate than Spain, the native land of the merino sheep, we are informed from the best authority, has been greatly improved in fineness by great attention being paid to the treatment of these sheep. Indeed, in our own island, Lord Western, at Felix Hall, in Essex, has, by devoting similar attention to feeding, sheltering, and housing in bad weather in sheds with yards his merinos, prevented any deterioration in their wool. His Lordship's best fleeces, we are informed, are not inferior in any respect to any that are imported from Spain, Saxony, or Australia.

7. As another advantage resulting from this mode of feeding it is agreed that, according to it, there is a much smaller waste of turnip; that we have it in our power to give the animals just what kind and quantity of food we may think proper; that these useful roots, the farmers chief dependence for the winter keep of his woolly stock, may be preserved to a late season of the year, when provender is most in demand for them. It is the opinion of good judges that the slicing of turnips, and putting them into wooden troughs to be eaten by the flock, makes these roots go farther by one-fourth than in the old way of feeding. Every part of the root is rendered eatable. To make the turnip, therefore, go as far as possible in feeding stock of all kinds, whether in the stall, the farm-yard, or the sheepfold in the turnip field, let no farmer be without the useful turnip-cutting machine. No one in Scotland is ignorant how much our sheep suffer in a late, severe, backward spring. If any plan can be pointed out, upon which flocks may be better supported at this pinching time of the year, it surely is well worthy the attention of their owners to examine how far they can introduce it. And all these matters are of the greatest importance, and closely connected with the interest of the husbandman.

8. That wherever an experiment has been made to pen or fold upon a turnip field, two lots of sheep, equal in all respects as to age and condition, putting at Martinmas the one lot into one fold, the other into another, and continuing to feed regularly the two lots; shifting at stated times the fold to fresh portions of the field, the one lot to be fed in the usual way on the turnips, having also oilcake pounded, salt, and cut hay and straw given it, but the other to have the turnips cut into thin narrow slices and placed in troughs before the sheep, it will be found the lot which has had the turnips supplied to them cut by the machine, with the oilcake, salt, and cut hay and straw, will be as forward in the middle of February as the former lot would be in April. But, should the two lots be kept feeding for twenty weeks, the lot which has had the turnips supplied cut into thin narrow slices will fetch from 4s. to 5s. a-head more than the individuals of the other lot; that this increased value of the sheep will cover all the expense of oilcake, turnip machines, and the extra wages of attendance in working them; and that a feeder will receive a handsome return, remunerating him for what may be held by those unacquainted with this mode of feeding an extraordinary outlay.

Thoroughly convinced of the advantages resulting from this method of feeding sheep, the English agriculturists are strenuously endeavouring to promote the introduction of the plan into those places where it is yet unpractised. Accordingly, we observe at the meetings of local agricultural societies in various parts of England, that different influential individuals of these bodies are coming forward to press upon the notice of the other members the benefit of this system, which fattens the sheep sooner, and increases the fertility of the soil. Lord Huntingfield, at the meeting of the East Suffolk Agricultural Association, on the 12th of September, 1839, "recommended every one feeding sheep to cut turnips for them; instead of turning sheep into the fields among the turnips, as the advantage of cutting them by machines was seen by the tendency and aptitude to fatten the animals." Another gentleman, Mr. Shaw, at the same meeting, stated:—

H

* See Complete Grazier or Farmer's and Cattle Breeder's Assistant, seventh edition.

"He agreed with Lord Huntingfield on the propriety of cutting turnips for sheep, instead of turning the flocks into the fields upon them, as had hitherto been the custom in this country. The system, he believed, was greatly increasing. For years past he had himself adopted the plan. He could not say, however, that the turnips went twice as far, but he believed that they went *one-third more than as far*; and if they made an addition of oilcake and cut hay and straw, feeding them with them as well as the cut turnips, they would find themselves amply repaid in their future crops upon light lands. He spoke confidently, because, where he did not formerly grow more than six coombs,* he had this year grown eight coombs; and that was the first time the crop had come round with wheat since the first time the turnips had been cut for the sheep, and oilcake and cut hay had been given them." (*Mark Lane Express*, September 23, 1839.)

In another part of England, viz., in Devonshire, we find at the meeting of the Taunton Agricultural Association and Cattle Show, at Taunton, on the 2nd December, 1839, Mr. E. A. Sandford, M.P., calling the attention of the members to the advantages of feeding sheep with cut turnips. "He advised them to draw their turnips, cut them with a machine, and supply the sheep with them in due quantities." (*Mark Lane Express*, December 9, 1839.)

Another illustration of the high estimation in which it is held in England, and of the anxiety of landlords to promote this improvement, is the fact, that premiums are offered by some to encourage the introduction of it upon their estates. On his rent day, in autumn, 1839, the Earl of Chichester offered a premium of a turnip-cutting machine to that tenant who had the best field of turnips, of not less than five acres, regard being had to the quality of the soil, and the general cultivation of the crops. (*Sussex Express*.)

In some parts of England the tenants have not turned a deaf ear to such important suggestions from their landlords, and are pursuing this new system of sheep feeding very extensively. The author of these observations was lately informed by a respectable tenant of the Earl of Leicester that he had fed in Norfolk last winter ninety-three score of sheep, folded on the turnip field, with these roots cut with the machine, together with pounded oilcake, cut hay and straw, salt, and occasionally bruised oats.

The preceding statements have been confined to the manner of fattening sheep profitably for market, when folded on turnips cut by machine. We might, however, have extended our observations, by pointing out the great advantages of taking greater care of our breeding ewes than we do, by giving them more shelter, and food of better quality two or three months before the lambing season commences. We are too much, in Scotland, disposed to manage our sheep, though the most profitable, with less care than any other of our domestic animals. We compel them to brave all the storms and hurricanes of winter. Were we, however, to expend on them somewhat of the attention we bestow upon our horses and cattle, and shield them by some shelter from the pelting of the merciless blasts of rain and snow, and feed them with some nutritious food, the flock would be much more profitable to its owner than at present, and many of those losses which of late years have but too often befallen the hapless ani-

mal be prevented. If some dry, snug, warm, sunny corner, not far from the barn-yard, were looked out, it would be no very costly affair for the storemaster to enclose a small yard with sheep-hurdles, of size to contain all the breeding ewes; to erect around the yard a low simple range of sheds, made out of any offal wood, or slabs or coarse boards about the premises. These sheds might be covered over with turf, broom, heath, or straw, if it could be spared. Let the breeding ewes be here confined every evening, and when the weather seemed likely to be stormy, wet, and boisterous, let them lie here, warm and dry, day and night. Under this management less tar and grease would suffice. The wool freed from these foul anointing substances would be whiter, and consequently bring a higher price. By bedding the sheep with straw, bracken or fern, or dried leaves, of which abundance in most places might be gathered in autumn, a great mass of valuable manure might be collected. The shelter of these sheds will ward off many fatal diseases to which the out-lying sheep are constantly exposed. By inserting, however, a letter on this subject, which appeared in the "*Mark Lane Express*" of 16th December, 1839, from Lord Western, of Felix Hall, Essex, our views on this subject will be more clearly conveyed than we can hope to express them in language of our own. With regard to sheltering sheep in winter, and otherwise managing them, Lord Western is surpassed by no breeder in the island, and any remarks proceeding from so high authority demand the most serious consideration of the intelligent sheep-owner.

"I have a flock of pure merino, and a flock of Anglo-merino, of which peculiar sort I have exhibited specimens at the Smithfield show and at Oxford, and shall again at Smithfield next month: I have now had three years' experience of the practice, and am decidedly of opinion, that the fatting stock thrive quicker, and the sheep with their lambs also do better than out of doors. I begin in November to put them into the yards at night, letting them out in the day. As the season advances I shorten their going abroad, till at length they are not allowed to go out at all, except that when there happens to be a fine sunny day in winter, I let the ewes and lambs out for two or three hours upon a piece of dry ground, on which I strew some cabbages or turnips. The yard of course must be well littered. I like the litter to accumulate to a considerable depth, so as it does not heat. I think the sheep tread the straw with their little sharp feet quite as effectually as bullocks; and the manure from them is better, dependent however upon what they eat, the higher they are fed, of course, the richer the manure. I place salt for them in the yards, and the ewes and lambs consume a large quantity, the young lambs eat it with avidity. The salt which I give is of pretty good quality, not rock-salt, but small salt of the inferior sort used at table. That sheep do not suffer from confinement I have abundant other proof; the merino rams fight so furiously that I often tie them up like horses in a stall, and keep them there from season to season, and they are as healthy as any that are out, and will get sometimes very fat. As a subject of curious experiment I kept three pure merino wethers every year in their wool, three successive seasons; from the time of their being sixteen months old till they were shorn of their three years' fleece they were never out of the house, and I never knew them otherwise than healthy and in good fleshy condition when stripped of their three years' old fleece. I sent one to Oxford that was exceedingly fat, after having a fleece taken from him that

* A coomb is equal to four imperial bushels.

weighed 28 lb., and I shall exhibit another next month extravagantly fat, with a fleece of 30 lb. weight. My folding-yards are spacious, and surrounded with sheds, these sheds are made in the cheapest possible manner, they are only ten feet deep and wide, and about six or seven feet high; built of that limited size, the wood which otherwise would be burnt is sufficient to build them, the posts are stuck into the ground with bearers across, and covered with haulm. Other materials better suited for the purpose may be used in some countries; furze will make good walls and covering also; some persons may think it good policy to build their sheds of superior construction, but excessive cheapness, though little durable, places them within the reach of small farmers with short tenures. I have now adverted to every circumstance calculated to recommend the practice of yard-folding of sheep, of which I am a decided advocate; and I protest I know of nothing that can render the policy of the system at all questionable, where the necessary means are attainable with any tolerable facility."

When turnips are grown on strong clay land, as in Ayrshire, and in other similar soils in Scotland, and cannot be eaten off by folding sheep upon them, they might be carted to such a sheep-yard, fitted up with sheds as just described by Lord Western, and there, being cut by machines, be given to the sheep, and in which yards they might be fed fat for market. The breeding ewes in all situations whatever, ought to have provided for them during the winter months such yards and sheds; and if erected of the same dimensions, and of the cheap materials recommended by Lord Western, there are but few store-farmers who would find them beyond their means. Having such care and such feeding bestowed upon them, fewer losses at lambing time, and earlier, larger, stronger lambs would be reared. We think these matters are well worthy the attention of the intelligent sheep-farmer.

In some parts of England we find farmers imitating Lord Western in feeding their breeding ewes during winter in sheds and yards. A respectable farmer in Suffolk states in the "Mark Lane Express," of December 23, 1839, "that he is now building a complete sheep-yard, with sheds, for 400 ewes, as his plan is to house them in winter. Last year he made 150 loads of manure, which would have been wasted or deposited where it would not have been available; and in my opinion it is equal to any manure for turnips."

An interesting experiment lately made with great pains and accuracy by Mr. John Wallbanke Childers, M. P., in feeding sheep in a yard with a shed, is detailed in the Journal of the "English Agricultural Society," vol. i. part ii. p. 169. This experiment supports the valuable advice given by Lord Western in the letter we have just inserted, on the great advantage of feeding sheep in winter in yards with sheds:—

"Having tried an experiment on the winter fattening of sheep this year, I think the insertion of it in your Journal may be desirable. It has for some time been my opinion that sheep would fatten more quickly in a yard than in the usual manner on turnips in the field. In consequence of this view of the case I last winter enclosed a small yard with posts and rails, and erected a low thatched shed, just large enough to allow a score of sheep to lie down at once. The floor of this shed was boarded with common rough slabs, and was raised eighteen inches above the surface of the ground, the boards being placed three-eighths of an inch apart, in order to allow the

free passage of water, and keep the boards dry, as my great fear was that the sheep might get the foot-rot.

"I then proceeded on the 1st January to draw forty wether hogs out of my Leicesters, and divided them into two lots, as equal in quality as I could get them. On weighing each sheep separately, I found the weight of one score to be 183 st. 3 lb., and that of the other 184 st. 4 lb. I put the first lot into the yard, and placed the other lot on turnips. The field was a dry sandy soil, and well sheltered, and peculiarly favourable and healthy for sheep. Each lot had exactly the same quantity of food given them, which was as follows:—"1st, As many cut turnips as they could eat, which was about 27 st. per diem for each lot. 2d, 10 lb. of linseed-cake, at the rate of half a pound per sheep per day. 3d, Half a pint of barley per sheep per day. 4th, A little hay, and a constant supply of salt. For the first three weeks both lots consumed equal portions of food; but in the fourth week there was a falling off in the consumption of the hogs in the shed of 3 st. of turnips per day; and in the ninth week there was a falling off of 2 st. more. Of linseed-cake there was also a falling off of 3 lb. per day. The hogs in the field consumed the same quantity of food from first to last. The result of the experiment is as follows:—

	20 Shed Hoggs.	Increase.	20 Field Hoggs.	Increase.
	St. lb.	St. lb.	St. lb.	St. lb.
January 1	183 3		184 4	
February 1 ..	205 0	21 11	199 8	15 4
March 1	215 10	10 10	208 2	8 8
April 1	239 9	23 13	220 12	12 10
Total Increase		56 6		36 8

Consequently the sheep in the shed, though they consumed nearly one-fifth less food, made above one-third greater progress. The circumstances of the experiment were, if any thing, unfavourable to the sheep in the shed; the turnips, by being stored in a house for their use, became drier than those consumed by the sheep in the field; and also in February the shed-hoggs were salved or rubbed with mercurial ointment, which is generally supposed to give a check to feeding sheep.

"N. B. The boarded floor was swept every day, and fresh straw was given after every shower of rain."

From this important trial of the comparative merits of feeding in an open field, and in a yard with a shed, Mr Childers establishes a very valuable fact, that shed and yard feeding of sheep economises greatly their food, and sooner fattens the animals, than leaving him to brave the inclemency of the elements out of doors.

In fattening of sheep, dryness of feet and of fleece are necessary; cold can better be endured than the former conditions. From the same experiment, we are also taught, that twenty sheep fed in the shed acquired not far from one stone per head more than twenty others of the same weight fed in the same manner in the field, from the 1st of January to the 1st of April. This increase of weight cannot be estimated at less than 8s. per head, and at 10 per cent. on the value of the sheep.

Having provided for the comfort of the breeding ewes, by sheltering them from the storms of winter in yards with sheds, let us not forget to provide the same comforts for the outlying flock folded on the turnip field, and consequently exposed to many a pelting shower of snow and sleet,

and many a biting blast. For that purpose, we think there might be contrived movable wooden sheds, which being placed on wheels, where the land was not too uneven, might easily and expeditiously be moved from one part of the field to the other, whenever it was intended to move the fold. The following dimensions are suggested :—

The shed to be made of any refuse sort of wood, to be about 7 feet wide, 5 feet high, and to be made in separate parts of 15 feet long each, and having a wooden floor or bottom. Thus the sheep would lie dry, as all moisture, from the boards or slabs being laid a little apart from each other, would pass away. This wooden floor to be placed on four iron wheels, which would raise the floor six inches off the ground. Into the wooden floor to drive four or more wooden posts, either

of fir or larch. Upon these the roof would be fastened.

The bars or hurdles used for enclosing the fold against which the movable shed would stand, to be roughly closed up with slabs or boards to prevent the passage of cold and wet through them.

When it was wished to move the fold to any other quarter of the turnip-field, two men or a poney would not be long in drawing the movable sheds to any part of the enclosure. The expense of each of these portable sheds would not exceed 4lb. About one score of sheep would be contained in one of them. Under these dry, warm, portable sheds, the fattening sheep would be comfortably lodged in all bad weather; and thus lying warm and dry, they would sooner take on flesh, and yield more wool.

Floor of Long Movable Shed.

Elevation of two Short Movable Sheds placed together, to form one long one.*Elevation of the end of either size of Movable Shed.*

In the particulars we have brought forward in favour of an improved system of feeding farm-stock, we have had it principally in view to call the attention of the Scottish agriculturist to the manner of feeding sheep on turnips in the eastern counties of England. Much however, of what we have stated in explaining the system of feeding sheep, is applicable to cattle. These animals, like sheep, have eight front cutting teeth, none in the upper jaw and only in the lower; and their front teeth in the lower jaw are liable to many of the accidents and changes from age that are attendant upon those of sheep. It is therefore as indispensable that cattle when fed on turnips, and which we wish to feed rapidly, and in the least wasteful manner, should have them presented to them cut into slices. The hay which is allowed them ought also to be cut for them by a hay-cutting machine. If this article be supplied them in racks, or in other ways, there will be a great waste, as the cattle, like horses, tread under foot nearly as much as they consume.

Whatever other food be given with turnips, let salt always be freely offered feeding cattle, as also cows, which makes the latter yield more milk.

We think that every one who reflects upon the subject will readily admit, that the mode of feeding which we have endeavoured to describe, is a material improvement upon that formerly pursued.

It recommends itself, not by any one, but many advantages.

1. It preserves the teeth of the hogg or young sheep, and the older animals; and, should these unfortunately have dropped out, enables them to

satisfy their hunger in a short time to rest, and to ruminate.

2. That they become fat in a shorter time.

3. This variety of rich food improves greatly the quality of the manure.

4. The poorer parts of any field may be enriched equally with the better parts of it, by keeping the sheep standing on them as long as it is thought advisable.

5. The wool, from the higher keep of the animal, is improved in quality, and increased in quantity.

6. The turnips can be husbanded, to feed more sheep, and preserved to a later period of the season, when they are most needed.

7. Experiments made upon two lots of sheep, in all respects equal, feeding the one in the old, the other in the new way, show the advantages of the latter over the former; the one lot, within the same time, greatly excelling the other both in flesh and fleece.*

* In confirmation of the statements we have advanced in favour of feeding sheep while folded on turnips, in the way just described, we have much pleasure to strengthen ours, by laying before the reader the opinions of one of the most intelligent and practical farmers in the Wolds of Lincolnshire. This gentleman, Mr. Francis Iles, of Barnoldby, not only farms his own beautiful estate, but rents a very extensive tract of land from the Earl of Yarborough.

This gentleman states, as respects the seventh statement we have put forward respecting the feed-

The above observations were collected during a recent visit to England. It is hoped the reader will overlook the imperfect and hurried manner in which they have been put together, and direct his attention to the considerations of the advantages which are certain to accrue to him by adopting the new and improved method of management pointed out. Our sole and anxious aim and

ing two score of sheep, one on turnips in the old way, the other by giving them cut by machines: "There cannot be a doubt, that the score which have the turnips cut for them will be much sooner fit for market, and will fetch from 3 to 6s., or, I think I might say, from 4s. to 8s. per head more than the others, that are not cut for them. There are many reasons why this should be the case: they get their food in a cleaner and more regular manner; and, when they become accustomed to the troughs, which they generally do in a few days, they can fill themselves in a much shorter time, consequently having a much longer period for rest, which is a very essential point. They also get their food much earlier in the morning, our plan being to cut a large tubful of turnips over night, which are served out to them the first thing in the morning, and during the time they are eating them, the man is cutting more for them, until they are satisfied, and go to rest; and, by the time they again rise, the troughs are all replenished, and so on during the day, always taking care to leave them full at night. Another reason why cutting turnips for sheep is so beneficial, is, that during the winter and spring months, the hogs lose their teeth always in the spring, and very frequently much earlier in severe seasons, from the turnips being hard from the frost. It is therefore obvious when this is the case, that cutting for them must be not only beneficial, but highly necessary, as it is impossible for them in that state to procure sufficient food in the natural way. Great regularity and good management, however, must be observed when cutting turnips for sheep. In fact every thing depends upon it, as, when the hogs have once become accustomed to the troughs, they require to be well served, and plenty cut for them, as they will not then look out for themselves, but appear to wait for a regular supply. I have in several instances seen the whole of the expense of cutting turnips thrown away by bad management, and want of regularity. It has become almost proverbial with us, "*better not cut at all than not cut enough*;" one man and a boy will cut for about 260 hogs, and do them well. I have at present four machines going, with a man and a boy to each; and these machines, worked by these hands, cut each for about 260 hogs. This season has been a very bad one for turnip sheep generally, having had so much rain. The sheep have scarcely ever been dry, and the land has been in a very dirty state. When hogs are fed with cut turnips, they are frequently made fat, clipped, and sold in the latter end of April and beginning of May. We sometimes give them barley and malt-combs. The latter answers well in the beginning of the season. We fancy it keeps them healthy. But oil-cake is more generally used than any other artificial food, as we find that the manure of the sheep fed upon it is highly beneficial to the land on our Lincolnshire Wolds. The sheep wooden troughs we use are of various dimensions and sizes. Those I use are about 10 feet long, 7 inches deep, with an 8-inch bottom. The trough is nailed upon two legs of wood, about 5 inches deep, placed about one foot from each end of the trough."

object in publishing these remarks, is the hope we cherish, that they may be instrumental in exciting inquiry among the intelligent tenantry of Scotland upon a subject so important.

Allusion having been made to Holkham, it may be observed, that, among the places visited, it is to be included. To the kindness and hospitality of the Earl of Leicester, the proprietor of that splendid estate, we are greatly indebted for an opportunity of inspecting all the operations, many of them highly interesting to the lover of good husbandry, in progress upon his Lordship's extensive and well managed farm. Here it was that the system of feeding sheep on turnips cut by machines were seen to the best advantage. Every one who visits Holkham must be struck with what that public-spirited and enlightened nobleman has effected during a long life devoted to agricultural pursuits. By continued and unceasing perseverance, Lord Leicester has converted an immense district of wilderness into a highly productive and beautiful country, yielding rich and luxuriant harvests,* adorned everywhere with woods in a most healthy and thriving condition, and managed on the most scientific principles, interspersed with farm buildings, commodious, and conveniently put down in the midst of the farm, in which will be found an industrious, hospitable, and well-informed tenantry, grateful to their liberal landlord for the comforts which they enjoy; among which, not the least is the secure holding of their farms, not the uncertain tenancy of from year to year, but on a lease of twenty-one years' duration. In this happy security in their tenure, we discover one of the main causes of the superior cultivation and prosperous condition of the tenantry upon the estate of Holkham.†

TRIAL OF STRENGTH.—Not far from this I saw a novel, and, to me, interesting trial of strength. The traces of a stout well-conditioned cart-horse, were attached to a splinter bar, which two men took hold of in their hands. They then placed themselves, so that their feet were against the side of a small grip in the road, and, in that position, tried their strength against that of the horse. He was, by word and whip, excited to put forth his utmost strength, but totally without effect. The two men held him back, without being moved from their position, so that he could not advance an inch. One of the men alone then tried the experiment; but this time the horse was easily victorious.—*Trollope's Summer in Brittany.*

* We are assured, from the very best authority, that, forty years ago, at the seaport of Wells, not far from Holkham, not more than 10,000 quarters of wheat were annually imported, for the supply of the neighbourhood. But now, from the great improvements of Lord Leicester on his estates, the same little port exports 20,000 quarters of wheat, though the population has perhaps doubled, or more than doubled, in that period.

† Having submitted these remarks on the improved method of feeding sheep, while folded upon turnips, we feel exceedingly anxious that it should be adopted more universally in Scotland. Might we suggest (without presuming too much) to the Highland and Agricultural Society of Scotland, to take into consideration the propriety of holding out a premium to those who should follow the plan described, and carry it out in the most perfect manner?

ON ERADICATING WEEDS.

"One year's good weeding will prevent seeding,
But one year's seeding makes seven years weeding!!!!"

SIR,—Your kindness in publishing my former letters prompts me to communicate something relative to the subject I have chosen for my motto, leaving it to you to publish or suppress, according to the merits or demerits you find therein. The present year bids fair to be one in which attention to weeding (strangely neglected hereabouts,) will be much called for, from the heat in April, and part of May, and the moisture since so favourable to the growth of "every plant, herb and flower." The infatuation of allowing weeds to grow and ripen with the crops has been often noticed. Still much remains to be said, and more to be done on that head, for active exertion becomes now necessary. I have often thought of the advice to farmers negligent in this all-important matter—"if you are so partial to weeds that you cannot do without them appropriate part of your land to their exclusive use, but on no account allow them a place devoted to other purposes." As surely as men do not gather grapes from thorns, or figs from thistles, so surely will they if not removed spring up with, and choke them. However, my present purpose is not to dilate on the evil of couch-grass, docks, &c., or any of the thorn or thistle family, highly injurious though they be, floating their seeds on gossamer wings wafted by autumnal gales to fields though distant, still under their baneful influence. A greater and more positive evil, sir, demands attention, at least in this country, for which it has so often been truly said, that "God has done so much and man so little." I do not exaggerate, sir, when I assure you, that many fields sown with Spring crops, such as oats, barley, and potatoes, instead of wearing nature's livery "sight-refreshing green," are like "blossomed furze unprofitably gay." Many such fields I could now point out, the crop of which I would not accept on condition of weeding it properly; for added to the expense (and heavy it would be,) I would only expect a short crop from the injury of that operation. I am not enough of a botanist to give the class, order, or even the name of the nuisance; and, perhaps if I was, a description may be more useful to those for whose information I write. I have observed three kinds, which I call wild rape, wild mustard, and wild turnip, from their likeness to these when under proper management; each variety producing yellow blossoms, and round seed containing oil. All seeds containing oil remain an incredible time without vegetating, when deep in the land, and only when by the action of the plough, harrow, &c. brought to the surface are seen to grow. Such I reckon the different cabbage tribes, also mustard, turnips, flax, hemp, furze, &c., the seeds of which when buried deep in the earth by the plough or spade, will remain for centuries in good preservation, and will certainly grow when brought to the surface by any of the afore-mentioned causes. When a seed once vegetates, and the young plant is destroyed, that seed will never grow again. Hence we may conclude that drilling green crops, especially potatoes, must be a great means of cleaning land infested with these seeds. To be more effectual an interval of a few days ought to be between the ploughings, hoeings, earthing up, &c., to allow time for the seeds brought to the surface to grow, that they may be destroyed, and others brought up by the next operation. A naked fallow also, using the same method of allowing between the several ploughings, harrowings, &c. time for the upper seeds to grow will have a good effect. Wheat sown in autumn seldom suffers much from these weeds, the frost of winter destroys them. The only means of removing them from corn crops is by hand, and the instant the yellow blossom appears, or even before, if possible, they should be drawn up, drawn out and destroyed. For if suffered to remain scattered about where they grow, many plants will produce seed, though pulled up before the pods are formed; and though such seed may be deficient in fulness, size, and colour, it will be found not deficient

in germinating powers, or in mischief to succeeding crops. In such times as the present, when we are paying cash for the produce of foreign countries to feed a half-starved, and whole idle population, it may not be amiss to call the attention of the thinking part of the community to this subject. For as we are now suffering a twofold calamity from the neglect of former years, to wit short crops and an increasing tendency to weeds, so doubtless will our successors suffer equally, or in a greater measure, if we fail in checking this evil. How many who are willing to work, are for want of it, wanting every thing—home, food, clothes? in short everything. The man who makes two blades of grass grow where only one grew before deserves well of his country, and the man who makes only one weed grow where two usurped the place, is no less its benefactor. Having trespassed thus far on my own limits, and on your columns, I now conclude, and remain,

Faithfully, yours, AN IRISH FARMER.

Kilkenny, June 8.

NEW SOUTH WALES.

It appears that the export of wool during the current year is expected to be no less than seven millions of pounds, being nearly a million more than 1839.

The following table has been published in the Sydney papers. It shows the great value of the British trade with New South Wales.

Return of the declared value of British and Irish produce exported to New South Wales in the year ending the 5th of January, 1840, with the proportion to similar exports from the United Kingdom in the preceding year to other countries.

The declared value of exports to New South Wales exclusive of the other Australian colonies, 5th January, 1840	£1,173,440
Exceeds the declared value of exports to Sweden	£102,647
Exceeds the declared value of exports to Norway	77,485
Exceeds the declared value of exports to Denmark	181,404
Exceeds the declared value of exports to Prussia	155,223
Ditto year ending the 5th of Jan., 1839, by more than one-half, amounting altogether to	516,759
It exceeds by one-tenth that of Belgium....	1,068,010
It exceeds by one-tenth that of Portugal....	1,165,395
It almost equals that of China	1,204,356
It almost equals that to the Australian Colonies generally	1,336,662
It is only one-fourth less than to Russia....	1,663,243
It is only two-fifths less than to Turkey	1,767,110
It is about three-fifths that to British North America	1,992,457
It is about one-half that to France	2,314,141
It is about three-fifths that to Italy	3,076,235
It is about one-third that to British West Indies.....	3,392,441
It is about one-third that to Holland	3,549,429
It is about one-third that to the East India Company's territory	3,876,196
It is about one-fourth that to the States of South America.....	4,726,905
It is about one-fourth that to Germany	4,998,900
It is about one-sixth that to the United States of America	7,585,766
The official value of exports on the 5th January, 1840, to New South Wales, was—	
British and Irish produce and manufactures	1,440,446
Foreign and Colonial merchandise	289,072

Total.....£1,729,518

Employing, with passengers, 416 vessels, with a tonnage of 48,911 tons; in return for which exports, this colony sent back in 1839, 6,894,864lb. of wool, besides oil from the fisheries.

In the month of January 990 free emigrants, and 213 convicts arrived at Sydney.—*Colonial Gazette.*

TO THE LANDLORDS OF ENGLAND.

GENTLEMEN,—In a former letter which appeared in the *Mark Lane Express* of June 8th, and in the June number of the *Farmer's Magazine*, I expressed my opinion that very great advantages would arise if the practice of letting farms on long leases, and of permitting a large proportion of the pasture lands throughout the country to be broken up, were universally adopted. I then stated my ideas fully on the former of these two subjects, and it only remains for me now to say a few words upon the latter. I cannot but think that if you were to bestow upon the subject half the consideration which its importance demands, you would not fail to see the superiority of the alternate system, especially when you remember that it is sanctioned by long experience in those parts of the kingdom where the cultivation of the soil has attained the highest state of perfection.

Much prejudice has been excited against the *breaking up of old turf*, as has been the case with many other excellent practices from similar causes, because some few people have run wild on the subject, and have asserted that *the whole* of the pasture lands of the kingdom, without excepting even the richest watered meadows, ought to be brought under the plough. In other cases, as for instance, during the late war, when from a temporary rise in the prices of agricultural produce, proprietors have allowed a part of their grass to be broken up, the farmers, tempted by the certainty of a large immediate profit, have taken successive crops of wheat and other grain from the "*fresh land*," thus exhausting it to such a degree as to render it unproductive for many years. In this way discredit has been brought upon the system itself, though had it been followed with judgment, very different results might have been expected.

But at such a period as the present, when we are making such rapid advances in agricultural improvement, when we have a Royal Society established among us for the purpose of bringing the old science and experience of the country to bear upon every subject which promises advantage to the landed interest, when large districts in various parts of the kingdom are teeming with a super-abundant population—a population, I believe, in most cases willing to earn their bread with the labour of their hands, if they had but the opportunity of doing so—surely at such a time as this, it is the duty of the landlords of England to shake off the trammels of prejudice, instead of being a clog upon the industry of their tenants, to take the lead and encourage them in every improvement, and when a system is offered for their adoption, sanctioned by the long experience of a sister country which promises to confer such important benefits upon all classes of society; the least they can do is to weigh well its merits, and unless the objections to it are great indeed to give it a fair trial.

Gentlemen,—I will not press upon you the argument that I might draw from the theory of fecal exudation, because as yet no *positive proof* has been discovered of its truth, although it must be allowed that facts are very strongly in its favour: neither shall I lay much stress upon the immense preponderance of useless or noxious weed in most old pastures, as that has been brought forward so often that it must immediately occur to every one as soon as the subject is mentioned, but I should like to bring before you the following considerations which

I think will be admitted by most of those who have paid much attention to the subject.

First—The increase of produce, and therefore of rent, which may be expected.

Second—The economical application of manure, large additional quantities of which would be raised.

Third—The experience of the best farming districts in Scotland.

Fourth—The employment in populous districts, and thence the decrease in the poor rates, and the comfort and prosperity of the agricultural labourer.

I believe no one will deny that the quantity of grain raised in this country would be enormously increased under the alternate system; but it may not perhaps be as generally admitted that the produce of the dairy and grazing departments would suffer little or no diminution. When however it is remembered that a large breadth of land would annually be sown with clover, vetches, and other artificial grasses, the produce of which, acre for acre, would in most cases afford double the weight of food which could be obtained from old pasture, and that that food instead of being destroyed by the treading of large animals would be mown and carried to the yards for the use of the cattle, it certainly does appear to me that so far from diminishing, their production must greatly increase.

If, for the sake of argument, it were admitted—which I am by no means disposed to do—that a cow will not give so much milk, or a feeding beast lay on flesh so fast when soiled in yards, as when allowed to graze at liberty in the field; still it must be remembered that two or three times as many cattle might be kept on the same food, and that although there might be a trifling loss upon the individual animal, it would be repaid over and over again by the additional number.

Secondly—Think of the great advantages to be gained by the increased quantity and improved quality of the manure that would be raised. The dung of cattle in the fields falls in one spot; all the moisture, which is the most fertilizing part of it, is dried away by the sun and air, and nothing remains but a worthless pancake, which prevents the growth of grass for a considerable time, and eventually produces very little good. On the contrary, were the soiling system adopted every particle of manure would be made the most of, it would be carefully turned and prepared before it is taken out on the land, and when carted out, it would be ploughed in immediately, and thus preserved from the deleterious effects of the sun and air.

The land which is now in pasture would be producing straw for litter, as well as artificial grasses for soiling the stock. I do not hesitate to say, that at least one-half of every load of farm-yard manure which is laid upon grass land is totally lost to all useful purposes, simply because it cannot possibly be protected from the waste arising from exhalation. What then must be the loss occasioned by allowing the dung to drop from cattle as they stand in the fields, without being mixed with straw, and without being fitted by previous preparation to afford immediate food to the roots of vegetables?

It may be said that these observations do not apply to the breaking up of the old turf, but simply to the advantages of the soiling system, which at first sight appears to have little to do with our subject; but I contend that where a large proportion of any farm is allowed to remain in permanent pasture, the soiling system cannot be adopted on a large scale, and therefore that any argument in favour of the latter may be applied with equal force against the former.

Thirdly.—The long practice and experience of the most highly cultivated districts in Scotland is so notoriously in favour of the alternate system, that it is scarcely necessary for me to say more about it. I would merely refer any one to Sir John Sinclair's work on the Husbandry of Scotland, a book written, as I believe, nearly thirty years ago. In a long chapter, near the commencement of the second volume, he collects the arguments on both sides, and comes to the deliberate conclusion that permanent pasture, except to a very limited extent, is perfectly unprofitable. So early did the agriculturists of Scotland find out a truth as yet undiscovered, or at least not acted upon throughout the greater part of England. I lay great stress upon this argument, for I consider it a very important one.

Fearfully—There are several districts of this country swarming with an idle, and therefore, for the most part, a depraved population. Inhabiting miserable huts, clothed in rags, and subsisting upon potatoes, they at present either drag on a wretched existence, a burden to themselves and to their parishes; or it may be still worse, they engage in dishonest practices, and help to fill the prisons of the kingdom. In such districts the advantages of the alternate husbandry are increased tenfold: every philanthropic and charitable motive is in this case added to those detailed above. I do not mean to charge the landlords of England with insensibility to the distress of their poorer dependents, or even with backwardness in alleviating their condition: such an accusation, I most gladly admit, would not be borne out by facts; but when I see, as has been the case more than once, a parish circumstanced as above described, and at the same time containing a large extent of grass land perfectly adapted to arable cultivation; when I see that under the present system that land does not maintain one-fourth of the families it is capable of supporting, I never can persuade myself that the landowners in such a district have ever seriously considered the subject, or that any thing more is necessary to secure the adoption of the alternate system than to lay before them the simple facts, with the arguments on both sides, firmly persuaded as I am that their interests are in this case identical with those of the unemployed poor.

I am not one of those who advocate the indiscriminate breaking up of every field of old pasture: there are of course situations, where, from local causes, a small extent of permanent grass is both convenient and profitable, such for instance as very rich old pastures in dairy districts, good watered meadows, steep acclivities where a plough could not work, very poor stiff clays that would not pay for cultivation, orchards in fruit counties, &c. &c. All that I maintain is this: that there is a very large extent of grass land in this country which might be broken up with great advantage to the proprietor, the occupier, and the public generally.

Since the above was written, I have seen in *The Mark Lane Express* a letter, signed by "A Landlord," inquiring who would break up pasture land with a repeal of the corn laws hanging over his head? Gentlemen, my answer to this is, that if the alternate system were extensively adopted, the corn laws would become a dead letter; the increased quantity of grain we should raise would effect their repeal to all practical purposes. The price of grain would fall, I admit, but the farmer would have a larger quantity to sell, which would more than make up for the decline in price. It must be more for his interest, and certainly for that of the community, to sell one hundred bushels at five shillings than fifty bushels at eight. The corn laws ought not to be

repealed; every principle of national justice would be violated if such a measure were adopted, but I do think it is incumbent upon the landlords and farmers of England to use every exertion to raise such a quantity of corn as will prevent the necessity of foreign importation. I maintain that this is in their power, and as long as they take no steps for the attainment of so desirable an end, they furnish their opponents with the only reasonable argument they have to advance in their favour.

The commutation of tithes has taken away another obstacle to this system. Fresh broken up land will no longer have to pay more tithes than it did while in grass; this will make a difference of some shillings an acre.

Gentlemen, I have now laid before you most of the arguments which occur to me at present for the adoption of these two practices, to my mind, most essential to the advance of agricultural improvement. I hope that some of you may be induced to consider the subject in all its bearings; and if, in consequence of what I have written, one long lease shall be granted, or one field of permanent pasture shall be broken up, I shall consider that these letters have not been unproductive of good. These subjects have been mentioned from time to time by individual writers in *The Farmer's Magazine* and other agricultural periodicals, but they do not seem to have awakened any general interest; the letters have seldom been replied to, and the arguments on both sides have never been canvassed, and it is principally for this reason that I have thus formally attempted to engage for them the consideration of the agricultural world.

I have the honour to be, gentlemen, your obedient servant,

L. B. W.

June 24th, 1840.

THE TURNIP FLY.—Although numerous remedies have been recommended to prevent the devastating ravages of this dreaded though minute insect, yet we gladly avail ourselves of any further information calculated to remedy the disasters it so frequently produces. In a work lately translated from the German of Vincent Köllner we have the following:—"M. Wundram, a clergyman at Danne, in Hanover, has proved, by many years' experience, the efficacy of the following recommendations; they are practical on a large and small scale, require scarcely any expense, and take proportionally little time. These remedies consist in the employment of infusion of wormwood and road dust. Boiling water is to be poured on a handful of wormwood, and suffered to stand from 12 to 24 hours, so that it may be perfectly cold; then put the plants that are to be planted out into the infusion, with their leaves downwards, as far as the stem, so that their roots may not be wet, and then put them into a cellar, or some other cool place. In six, eight, or ten hours afterwards they may be planted with the certainty that scarcely an *earth-flea-beetle* (another name for the same insect) will attack them. The bitterness lasts so long that the plant seldom requires to be sprinkled in its new station, unless frequent heavy rains fall soon after planting it out; then it would be a good thing, the next fine day, to sprinkle the leaves with this infusion, by means of a wisp of straw. Young plants and seedbeds, whether sown with the various sorts of cabbage and turnip seed, radishes, cresses, or tobacco, &c., will likewise be successfully secured from the *earth-flea-beetle* by a gentle sprinkling with this infusion of wormwood. Plants may also be rescued from the greedy voracity of these small devastators in a more simple and easy manner by the application of the second remedy—viz., road-dust. The dust of chalky stones is to be gathered on the road in a fine day, and stowed up in a dry place for future use. As soon as it is perceived

that the earth-flea-beetles appear on seed or plant beds, a night must be chosen when a great deal of dew has fallen; and, while the young plants are still wet, they are to be thickly sprinkled with the road-dust, till they look as if covered with powder. Whether the dust is injurious to the bodies generally, or only that by covering the leaves it obstructs or is injurious to the action of their masticating organs, is not known; but the earth-flea-beetles all at once disappear from the seed and plant beds, particularly if the sun shines brightly the following day, and the dust is dried on the plants. If heavy rain falls immediately after the first sprinkling, and washes off the dust, it must be repeated as before. The application of the infusion of wormwood and the sprinkling with road-dust are practicable also in field cultivation. M. Wundram asserts that he has always preserved his flax and summer and winter corn, as well as white turnip field, from the *hallice*, by these means."—*Barrow's Worcester Journal*.

OVER STUFFING BREEDING STOCK.—FEEDING OFF TARES WITH SHEEP, &c.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—All agriculturists, desirous of benefit from the improvement of stock, should carefully peruse the letter in your last paper, bearing the signature of a member of the Royal English Agricultural Society; I called attention to the subject last year, immediately previous to the Oxford Meeting, but I fear with as little success as the present complainant is likely to experience; for as long as such leading stars as Lord Spencer and other noblemen, amateur agriculturists, will take the lead in contesting who shall produce most waste (as the fat we see on prize animals undeniably is,) instead of the most eatable, wholesome mutton or beef, so long will the stars of a lesser order imitate the mischievous example. I happen to live in the neighbourhood, where the successful candidate for South-Downs, at the Oxford meeting, feeds his show-sheep; I know they neither had the rain or dew of Heaven on their backs for six months previous to the exhibition, and that the lambs were never in an arable field!! Again; I was examining the wool of one of the prize Cotswold rams, when I was requested very civilly, certainly, not to touch it, lest I should make its back sore! the skin being distended to its utmost stretch, by means of cake, corn, and unnatural housing—are these the objects, I would ask, of the practical members of the Royal Society? I trow not, and by the preference given to such unnatural and expensive forcing, I know that three-fourths of the best breeders are deterred from exhibiting. In Hampshire, we get our stock fatter than most palates would fancy, in the open field, consuming the produce where it grows—the grand object of the green crops system on all light soils; why then should we, and others like us, pursuing as I believe on all hands will be admitted, the very life and soul of good husbandry, in thus consuming and spending on arable lands, the green crops raised thereon as dressing for the next corn crops, be driven from the field of competition, merely because those to whom expence is no consideration, are permitted to hide all the defects of growth, by overloading the animal with useless fat, unnaturally acquired in barns or stalls? I contend, Sir, that the real symmetry of a sheep is not to be ascertained, when so loaded; its constitution is

lastingly injured; its progeny is sure to be weakly and degenerate. I am aware of the difficulty of confining competitors to any particular mode of feeding, but I would suggest the following plan as an antidote to over-fattening. Let the standard of merit be the possession of a majority of good points, such points to be defined in printed rules; these points are best developed in condition of mediocrity, and when the animal shall be so overloaded as to render it difficult for the judges to ascertain *any one* point correctly, let it be discarded as ineligible to compete. On the subject of

FEEDING OFF TARES WITH SHEEP.

Observing no answer given to your correspondent "Northern," I beg to give him below, the system we pursue in Hampshire, in sowing and feeding off this valuable green crop. On quick, moderately good soils, we begin sowing them early in September,* on the wheat stubbles which we intend for backward turnips the following season; we sow at intervals of a fortnight, so that the tares may not all come to maturity at once, continuing up to the first week in November. When we have sown all the land, which seems fitted to be followed with turnips, we sow the remainder of the crops on such *strong* land, after rye-grass or clover, as is intended for wheat the following year; on this description (strong) of land we consider tares a good preparation for wheat. It is our custom to make off our sale lambs at a fair (Overton,) held on the 18th of July, then from five to six months old; with these we begin feeding tares about the 1st of June, waiting, however, if possible, until the blossom begins to appear, considering them then more nutritious and wholesome. We set out three pitchings, or folds of tares; our sale lambs go first, and have two of these pitchings a day, cropping off merely the tops, or about three inches in length of the haulm; the stock or ewe lambs follow next, and the stock ewes come last, and clean all up, with the addition of a picking of sainfoin or clover (there is no need of both); a good description of wether Lamb, will, at the above age, arrive at 7, or 7 $\frac{1}{2}$ stone of 8 lbs., without corn or cake, and go to fold every night: we consider tares the very best of food for forcing lambs in dry weather; in wet, they should have more outlet; if a very bulky crop, it is best to cut them up, and give them in racks or cages for ewes or wethers, but this system will not do for forcing young lambs, as without a choice, and plenty of room to pick, they will not thrive. The small quantity of manure dropped by the lambs, over, comparatively, so large a space, does not in the least injure the feed to the flock coming after.

As to the quantity of sheep a ten acre field will carry, much of course must depend on the crop. Half an acre of good average produce, will maintain 200 lambs and 200 ewes per day, in good condition. I am Sir, yours respectfully,

J. T. TWYNAM.

Whitchurch, Hants, June 25th.

PALM TREE.—The Palm tree is found in a variety of the warm countries in the south of Asia, and the north of Africa; they are numerous on the banks of Jordan, but the best were those around Jericho and En-gedi, which latter place is for that reason called Hazazon-tamor, the cutting of the palm-trees. This

* Of course I am here speaking of winter tares, if any are sown after the period named, it is on good land, well manured, early in the month of February.

tree grows very tall and upright, and its leaves retain their greenness throughout the whole year; the more it is exposed to the sun the better is its growth. Palm-trees produce but little fruit, till about thirty years old; after which, while their juice continues, the older they become the more fruitful they are, and will bear three or four hundred pounds of dates every year. The date is a most sweet, luscious kind of fruit, on which most of the inhabitants of Persia, Arabia, and Egypt entirely subsist. A species of rich honey or syrup, and a spirituous fermented liquor called araky, are obtained from it; there is also extracted from the palm tree a kind of wine, which is perhaps what the Scripture calls *shikhar*, or strong drink. As the sap is chiefly in the top of the tree, when they intend to extract a liquor from it, they cut off the top where there is always a tuft of spring leaves about four feet long, and scoop the trunk into the shape of a bason; here the sap ascending lodges itself at the rate of three or four English pints a day, for the first week or fortnight; after which it gradually decreases, and in six weeks or two months the whole juice will be extracted. As palm trees were accounted symbols of victory, branches of palm were carried before conquerors in their triumphs; and in allusion hereto, the saints are said to have palms in their hands, to denote the victory over sin, Satan, the world, the persecutions of Antichrist, &c. Rev. vii. 9. A remarkable experiment to prove the fructification of this tree, occurs in the 47th volume of the "Philosophical Transactions." There was a great palm tree in the garden of the Royal Academy at Berlin, which flowered and bore fruit for thirty years, but the fruit never ripened, and when planted it did not vegetate. As this tree Linnæus discovered to be a female plant, and as there was no male palm in its vicinity, the flowers never came to maturity. At Leipsic, twenty German miles from Berlin, was a male plant of this kind, from which, in April, 1749, a branch of flowers was procured, and shaken so that the dust, or farina, fell upon the flowers of the unfruitful tree. This experiment was so successful, that the palm tree produced more than a hundred perfectly ripe fruit, from which they had eleven young palms. On repeating the experiment next year, the palm tree produced above two thousand ripe fruit. This experiment fully established the fact attested by the ancients concerning the palm tree, which some have regarded as fabulous. This tree exhibits great variety in fruit, size, quality, and colour; twenty different kinds have been enumerated. Perhaps no tree whatever is used for so many and such valuable purposes as the palm or date tree; even the stones are given to camels and sheep as food.—*Bible Botany.*

SMALL ALLOTMENTS.

A large landed proprietor in this county, wishing to promote Spade Husbandry from seeing its favourable results in your valuable Magazine, has determined to divide an overgrown farm into small Holdings. Any of your correspondents will do much service by pointing out a plan by which four or five acres under the spade (with the assistance of a donkey and cart to draw out the dung,) could be made most beneficial to an industrious man with a family, all of them (except the youngest) able to render some assistance in dibbling, weeding, &c.—The question is, whether a man so situated can manage such a quantity of land as would enable his family to live comfortably, and whether he would not have some spare time to assist his neighbours. A few men who could be depended upon for a job by the piece would be desirable in any place, and some gentlemen in this neighbourhood contemplate advancing the sum necessary to try this experiment, proposing to give you from time to time an exact account of the results. I am, &c.,

A RESIDENT NEAR LANGLEY, SUSSEX.

OBSERVATIONS ON MR. WILSON'S PAMPHLET, ENTITLED "INFLUENCES OF THE CORN LAWS, &c."

TO THE EDITOR OF THE LEEDS INTELLIGENCER.

SIR,—My attention was first called to this publication by the high encomiums passed upon it by the Anti-Corn Law press, and more especially by extracts published in the "Leeds Mercury" of the 18th of April. The table there sets forth is a most valuable document, and contrary to the intention of either Mr. Wilson or of the editors of the Mercury, affords such abundant proof of the excellent working of the present corn laws that, after a calm and dispassionate examination, no one, I think, can deny that these laws are highly beneficial, and ought to be preserved; all this I said in a letter dated the 23rd April, and published in the "Leeds Intelligencer," and other papers. Having been thus called upon, I have read the book, and from the style in which it is written, I am not surprised that it should have attracted notice. There are many passages in it which I should have been proud to have called my own; it does not deal in that vulgar abuse and vituperation too common in works advocating a repeal of the corn laws. But there is not in the whole book one line to prove that the present corn laws have acted prejudicially on the country, nor yet one to show that a repeal of them would produce the slightest benefit. The fundamental argument of the author is intended to show the injurious effects of fluctuations in the price of wheat, and that the present corn laws necessarily produce great and frequent changes of price; he calls these "the extraordinary fluctuations which have taken place of late years in the price of wheat." This he says, "must ever continue to be the result of protective and prohibitory laws, because from this necessary tendency the whole of the evils of the present system have arisen." In speaking of the prejudicial consequences of the present corn laws and those of 1815, he says, "the most striking feature is the great inequality and fluctuation of price;" he says also, "no article of extensive consumption in this country ought to be, from the nature of its production and consumption, so free from fluctuation as wheat." I cannot possibly agree in this opinion. Wheat in its production is subject to vicissitudes of great extent; even in this happy climate a difference of produce amounting to one-fourth or one-sixth has been often known, whilst the absolute necessity of it makes the consumption regular. Mr. Wilson says, "it is therefore plain that inequality of demand cannot be the cause of fluctuation of price." True, and this very equality of demand, with inequality of supply, has, and must for ever, I apprehend, occasion fluctuation of prices. If bread corn were as unnecessary as nutmegs, or other luxuries, a high price would lessen the consumption; so far from this being the case with wheat, I fear the poor man, when bread is dear, eats less meat, and therefore requires more bread than usual. But as far as I know, it has ever been a rule in logic first to establish the premises upon which the argument is founded. Mr. Wilson has not done this, nor is it possible for him to do so, because the assumption has no foundation in truth. In answering this, the first and greatest charge which Mr. Wilson has made against the corn laws, I shall of course confine myself to the present corn laws, it being both useless and absurd to defend laws which have long since been repealed. Now it is quite impossible to suppose that Mr. Wilson has made this heavy accusation against the present corn

laws, for the purpose of misleading his readers, at the same time it is difficult to imagine how such an acute writer could have overlooked facts which had been publicly stated over and over again, and the truth of which could have been so easily ascertained. To show how much Mr. Wilson errs in speaking of the ill effects of the corn laws, when he says "the most striking feature is the great inequality of fluctuation of price," I will quote from a table published from Parliamentary returns, which gives the price of wheat in each year from 1797 to 1840. This table shows the rate of fluctuation per cent. in every period of five years down to 1833: thus from 1797 to 1802 the fluctuations are stated to be 220 per cent.; from 1802 to 1807, 100 per cent.; from 1807 to 1812, 74 per cent.; from 1812 to 1817, 183 per cent.; from 1817 to 1822, 143 per cent.; from 1822 to 1827, 81 per cent.; and from 1828, the first year of the present corn laws, to 1833, the fluctuations only amounted to 40 per cent. As this table goes no further, I must myself calculate the next five years, but to remove all doubt of the accuracy of my calculations, I will give the Parliamentary returns for these five years; they are 1833, 53s. 1d.; 1834, 46s. 2d.; 1835, 39s. 4d.; 1836, 48s. 6d.; 1837, 55s. 10d. The fluctuations are therefore nearly 42 per cent., and I can see no reason why the fluctuations in the following five years should be much greater. The steadiness, as well as the moderation of the prices of wheat in the last two years, notwithstanding the very great deficiency of the crops, prove how much the present corn laws tend to keep prices equitable. I therefore think the assumption that the corn law is injurious, by causing fluctuations in the price of wheat, is disproved, and of course all the arguments founded upon it perfectly useless. The average amount of fluctuations in every period of five years for the thirty years immediately preceding the passing of the present corn laws having been 133 per cent., and the average of each five years since the present law being only 41 per cent., the proofs of the advantage of the present corn law in preventing great fluctuations in the price of wheat is so triumphant as to leave no doubt of it.

There are two other positions which Mr. Wilson seems anxious to establish—one is that the fluctuations in the price of wheat are not to be attributed to good or bad seasons. He says, "we must at once banish from our mind the commonly received opinion that the fluctuations of prices are caused by favourable and unfavourable seasons." He says they are the effect of speculations arising from previous high or low prices. Now there can be no doubt that improved or neglected tillage would in a few years materially alter the quantity of the productions of the earth, and that high or low prices would influence the cultivation is equally certain; but to deny that good or bad seasons alter these productions in a still more sudden manner, is to deny that which is as clear as noon-day sun. Thirdly, Mr. Wilson asserts that the repeal of the corn-laws would not reduce the price of wheat, but the contrary; the way in which he says this, has all the marks of sincerity. He says this opinion is totally different from what either the agriculturist or the manufacturer hold. True, and it is not very wonderful that people should expect when the market of supply is widely extended, and the demand not in the smallest degree increased, that a fall of prices should follow; what may be the effect produced by a continuation of low prices is another question; but Mr. Wilson anticipates no decline of prices. My opinion, however, is, and always has been, unless the seasons prove very ungenial, or the British farm-

ers have a full anticipation of the change, and reduce their cultivation immediately, that a great reduction of prices will be the consequence of the repeal, and I think the natural effect of this reduction (which Mr. W. seems so well to understand,) being that British husbandry will be so much reduced as to occasion in unfavourable seasons, and when our continental friends either cannot or will not minister to our wants, such an advance in the price as has not been known here for many ages past. To preserve a steadiness of prices in corn has always been my most anxious desire, and I know of nothing so likely to effect this great blessing as the preservation of sliding duties, and the maintenance of that law, unaltered, and in all its integrity which has hitherto produced this happy effect. Had this gentleman been more happy in proving his propositions, I should gladly have given him credit for being more able to discuss the merits or demerits of the present corn-laws; but though he has as I think failed in proving any one of them, let us not deny him praise for what he has done aright. Many passages in his book proclaim a wise head and a kind heart. I will give two short extracts of that description, he says "wherever provisions are dearer, the condition of the bulk of the labourers is decidedly best, and their ability to command the necessaries, comforts, and even elegancies of life, form a striking contrast with the extreme difficulty with which even the barest necessaries are obtained, where they are cheapest;" he says, "compare the condition of the whole labourers of this country with that of any of the countries on the continent where provisions are at the lowest prices, compare their diet, clothing, and habitation, with what are allotted to the labouring classes in Prussia, Poland, or France, and see how superior the worst classes are in these respects in this country compared with the very best in those of supposed abundance and cheapness." The publication of such truths as these, is deserving the highest praise, especially when produced for the benefit of the anti-corn-law people. Mr. Wilson's fourth and last proposition is, "What change in the present corn-laws would best suit the interests of all parties?" To this I do not think it necessary to reply, because I think they require no alteration, and because to concede any thing material would be to destroy. I think the time has now arrived when I may properly retire from the controversy on the long agitated question of the "corn-laws." I entered upon its discussion for the purpose, solely, of explaining to my countrymen, in the best way I was able, the nature and operation of these laws, and if possible to convince them that, whilst affording a fair, and but a fair protection to the British farmer, they did not injuriously affect the commercial and manufacturing interests of the country. I have also been anxious that a question involving such vast and complicated interests should be discussed with temper and sobriety of language, and the progress of the argument in favour of these laws have convinced me that the good sense of my countrymen is not to be abused with impunity, but that time and reflection only are necessary to ensure from them a fair and candid judgment, and I trust that henceforth nothing will occur to disturb that friendly feeling which it is essential should exist between the agricultural and commercial communities. In looking back upon what I have written on this subject, I feel that I may congratulate myself in having abstained from all asperity of expression, nor have I, to my knowledge, violated, in a single instance, that respect which was due to those who differed from me in opinion. I have been deeply impressed with a

desire to disabuse the public mind of what I considered very erroneous opinions, and unfounded prejudices, and for this purpose I offered the benefit of my long experience upon subjects connected with the corn-laws, and I hope I have not wholly failed in my object. I beg leave, Sir, to thank you for the readiness with which you have published my letters in your paper, and to offer the same acknowledgment to every other Editor who has condescended to give them insertion. Should any thing arise to require it, I shall be at my post, but I feel persuaded the advantages of the present corn-laws are now more known and better appreciated than at any former period, and I most sincerely hope the agitation of the question will cease.

I am, Sir, your most obedient servant,
Nassau Cottage, Leeds, June 9th. JOHN BAKER.

DISEASE AMONG PIGS.

Sir,—Knowing the readiness with which you are willing at all times to throw open the columns of your widely circulated journal, by giving publicity to anything which might seem beneficial to the community, I shall crave your indulgence whilst offering a few theoretical remarks on a disease at present very prevalent, and in almost every instance fatal among pigs, in the North of Ireland. I say *theoretical*, because my limited experience would not warrant me in saying, that the treatment which I have hitherto adopted, and the medicine which I have hitherto administered, would invariably act as a specific; however the favourable result in the few cases which came under my observations has made a very strong impression on my mind, and if the observations which I am now about to make be the means of rousing the attention of intelligent farmers, or any other class of individuals, to the subject, my object shall be obtained. The first symptom of disease is manifested by the animal all at once refusing to take its usual food; and when kept in an enclosed yard, which is often the case, if a handful or two of soft grass or clover be thrown it, it will eat voraciously.—By and bye, it will refuse this also, and swallow nothing except some fluid, which more or less it will do, till within a short period of its death. During the progress of the complaint, the skin becomes exanthematous, at first appearance like flea-bites about the ears and neck, gradually spreading over the whole body; in a short time the eruption takes the appearance of measles in the human subject, and finally the whole skin is one universal patch of floridity. In some cases, a froth is observed working from the sides of the mouth, the belly shrinks, and the back becomes arched. On examining the stomach and bowels after death, the inner coat will be found nearly as red as the skin; which in a physiological point of view is not to be wondered at, when the peculiar sympathy existing between the skin and intestines of different animals is kept in consideration. The stomach is invariably found in an overloaded state with whatever the animal had last swallowed, and that in an undigested state; the remainder of the alimentary tube will also be found in the same loaded state. Now, from all the symptoms taken conjointly, and from the appearances which present themselves on a minute examination, after death, my firm conviction is, that the commencement of the disorder may, with great propriety, be denominated *inflammation*; which, if not arrested at the very commencement, will take,

with great rapidity, its most unfavourable course, and ultimately end in gangrene. The great obstacle, then, in the treatment of inflammation in pigs is the difficulty, I may say impossibility, of taking away a sufficient quantity of blood, in order to arrest the complaint. I am aware of the common and barbarous practice of cutting off the tail, but to use a common phrase, this is only “shooting at the moon.” As blood-letting, then, is out of the question, there should not be one moment lost, when the symptoms of the disease have shown themselves, in applying whatever medicines are most likely to control inflammations in general; and of these there is none more powerful than *Tartar Emetic*. When the symptoms of the complaint begin to show themselves, I would strongly recommend the propriety, nay, the necessity, of procuring *instantly* twelve grains of tartar emetic, dissolving it in a quart of cold water, and, of this solution, let one-half be administered immediately. This quantity I would give to a grown-up pig, and, of course, vary according to circumstances and sizes. If this quantity do not sufficiently vomit the animal, in the course of half-an-hour, I would give naggin doses, of the remainder of the solution, every twenty minutes, till the stomach be completely cleared. After you have had the stomach sufficiently cleared, the next object will be to unload the intestines, and the best means of doing this, is by giving scruple doses of calomel every hour, for three or four hours at the same time freely administering injections. By the above apparently simple treatment, and a perseverance in it, I have lately seen two cases, where, after the eruption had appeared, the disease seemed to be completely checked, and the animals got quite well. I would here remark, that for a long time back there has been an impression on my mind, that a great number of pigs are lost from a neglect of having their meat sufficiently seasoned with salt. I am inclined to think that the above hints, if attended to, would much excel in usefulness the few nostrums of those would be veterinary surgeons, cow-doctors, brute-quacks, or “skilled men,” whose obstinacy and self-conceit are generally only surpassed by their ignorance, and to attempt to reason with, or persuade whom, is often as much in vain as their traditional prescriptions. Hoping these observations may be the means of exciting farmers and others, who may be so unfortunate as to have pigs affected with the complaint, to a consideration of what has been suggested, and letting the result be made public, I remain yours, &c.

C. M.

A NEW AND EFFECTUAL METHOD TO KYANISE TIMBER.—Within the last two or three weeks the Manchester and Birmingham Railway Company have commenced Kyanising their wood sleepers in a much more quick and effectual manner than by the old mode of simply depositing the timber immersed in the prepared liquid. The company have had made a large iron cylindrical vessel, weighing about ten tons, and which is about thirty feet long, and six or seven feet diameter, made from wrought-iron plates, five-eighths thick, and double rivetted, which vessel is capable of resisting a pressure of 250lbs. on the inch. This vessel being filled as compactly as possible with wood sleepers, twelve inches broad and seven inches thick, the liquid is then forced in with one of Bramah's hydraulic pumps, and worked by six men to a pressure of 170lbs. on the inch. By this means the timber is completely saturated throughout in about ten hours, which operation, on the old system, took some months to effect.

ON THE USE OF GYPSUM.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—I have for many years past sown gypsum as a top-dressing for lucerne, clover, sainfoin, and tares, and this year I have experienced the same beneficial effects as before, by an increased produce of from ten to twenty cwt. per acre. Last year I procured some gypsum for a friend of mine to sow on his sainfoin, and in order to give it a fair trial, one part of the field was left unsown; the part sown was a lodged crop, and the other a deficiency of from ten to twenty cwt. per acre: this year the sainfoin was not gypsum'd, but there is quite as much difference in the crop; and when broken up and cropped with corn it is very visible. If the Royal English Agricultural Society publish the prize essays on different subjects, I think that they will produce some valuable information. VERITAS.

GYPSUM.

SIR,—I should be much obliged if your correspondent "Veritas" would inform me, through the columns of your paper, what description of land his is, the quantity of gypsum he sows per acre, and the time of sowing it, because the result of his experiment is very different to mine in the second year. I applied it first last year on sainfoin, and the result was an increase of 20 cwt. per acre; part of the field was not sown with gypsum. This year that part not sown last year is much the best, and the part where it was sown, the plant is almost all gone. I should suppose from its being forced so much last year, the field was a gravelly soil; the gypsum sown the middle of May at 3 bushels per acre.

OCCATOR.

ON GYPSUM, &c. &c.

SIR,—I have often seen in your paper strong recommendations of gypsum as a top-dressing for clover, but I cannot find any one in this neighbourhood who knows how it is used, and I should be much obliged if your correspondent "Veritas" would inform me, through your paper, where it is to be obtained, how it is to be prepared for manure, and the quantity per acre for clover. It is, I believe, only to be obtained here in the shape of stone, and if it must be burnt before applied as manure, how is this effected?

While I am writing, I would suggest that some remarks on any vegetables or fruits, particularly good of their kind, as sold in Covent Garden Market, would be acceptable intelligence to some of your subscribers, who like myself live at a distance from London, and know not the new and good things that are introduced into the vegetable world.

What is the finest variety of Rhubarb cultivated, and where can I obtain some of a scarlet colour through and through? I saw Bradford's scarlet Goliah recommended the other day in St. James's Chronicle as the best sold in Covent Garden Market. Is this the case, and where may it be purchased?

I have now asked so many questions, that I cannot finish without answering one of your correspondents, who wished to know a remedy for what we in Cornwall call the "gapes" in chickens, which disorder may effectually be cured by putting the diseased creatures in a tub, covered over with a thick cloth, and then filling the tub with smoke from a tobacco-pipe, which may be easily done by a person smoking a pipe and puffing the smoke under the cloth from his mouth; if one smoking is not sufficient, they may be subjected to a second and a third; but if young chickens are kept from dirty water and filthy open drains they will, I believe, never get the disorder. Let only your Devonshire correspondent take a brood of young chickens into a field, confine the mother in a coop, and give them a good supply of meat and clean water, and she will soon perceive the cause of

her chickens "gaping;" their little throats get filled with small red worms of the shape of earth worms (generated probably by filth), and this causes them to be continually gaping, and many of these little worms may be extracted by twisting round the inside of the throat the feathered part of a goose-quill. The chickens should be smoked till they are stupified.

I am, Sir, yours &c. &c.,

Cornwall, June 19, 1840.

A. B. C.

ON THE FLY IN SHEEP.

SIR,—Could I beg the favour of some of your numerous, talented, and practical correspondents to give me their opinion upon a circumstance that has occurred in my flock? On the 12th inst. my shepherd found six sheep which had been struck by the fly, and a few maggots were upon each of them; it being the night previous to the commencing of clipping, he shorn the whole of them and applied a small quantity of tar to the parts affected; the skin was not perforated, and apparently the animals did not suffer from the attack, at all events their health did not appear to be affected; twenty-four hours after two of them died, from what I suppose to be the application of tar.

I find Blacklock, in his treatise on sheep, strongly reprobates its application, which he describes as being too cantering in its effects. While in a work on sheep, published by the Society for the Diffusion of Useful Knowledge, I find the author recommending spirits of tar to be applied; now these opinions I conceive to be completely at variance with each other, and I shall feel obliged by some of your scientific correspondents setting me right on that score. The questions, I would ask, are these:—

1st.—Did my sheep die because tar was applied? (they were examined post mortem) and not the least indication of any internal disease was perceptible.

2nd.—What is the difference between tar and spirits of tar?

3rd.—How do those substances act upon the animal system when applied in the manner my shepherd applied them?

My father always made use of the ingredient tar, mixed and unmixed with other substances, to parts affected, after the sheep were shorn, and most of my neighbours do the same, but I never heard of anything unfavourable being the consequence, so that to the present I have not been compelled to act contrary to my forefathers and those around me, but have thought well to adhere to an application supported by long usage sooner than search for a new one. However, I think now that something must be wrong, and shall take it as an especial favour if some of your numerous and well-informed correspondents will give me their opinion upon the subject. Yours &c.,

A NOTTINGHAMSHIRE FARMER.

P.S.—I find the corn law question has not yet subsided; my opinion, as an extensive farmer, is that high prices of corn will ruin more farmers than any other cause, and that both landlords and tenants are immense sufferers by the present corn laws. I am farming in the counties of Nottinghamshire and Derbyshire, and have not the least hesitation in saying that, so far as my knowledge of facts lead me, that three-fourths of the farmers are ruined by (what may seem strange to the great bulk of our agriculturists) the high value of grain. I cannot, within the space of a letter, fully explain myself, but of this I am certain, that if high prices continue, a many, very many, of the farmers will, ultimately, have to kick the workhouse door for admittance.

TO THE EDITOR.

Sir,—Your correspondent, "A Cornishman," complains of his inquiries respecting Cotswold sheep not being answered. I have been a breeder of Cotswold sheep on the Gloucestershire Cotswold-hills for about 20 years, and will conscientiously answer his inquiries without prejudice to either Cotswolds or Leicesters.

The improved Cotswold sheep are hardy, of good constitutions, good wool growers, good sucklers, and are fit for the butcher at an early age.

My regular flock is 500, I am a moderate keeper, my yearling sheep average about 10 stone each, the average weight of wool has been 115 tods per year, 28lb. to the tod, viz., from 250 ewes and 250 tegs, making together 500 fleeces. The weight of wool and mutton could be greatly increased by superior keep, though I doubt whether it would be more profitable. I am stating exactly what moderate keep has done, for your correspondent's information.

A few years ago I was induced to cross part of my ewes by a thorough-bred Leicester ram from a first-rate Leicester flock, the result was as follows:—The first summer the lambs were very pretty and pleasing to the eye—I found at winter they could not endure the inclemency of the weather; they appeared always starved when my own sort appeared quite comfortable. At shearing time they were very deficient in wool; I sold the males at the usual time I did my others (always kept together), they were very much less in weight, and what surprised me more was, the butchers declared they were of a worse quality than my original sort, having too much fat for the lean, which did not please their customers.

The females I put to the ram, but they proved bad sucklers, their offspring were pretty but not profitable to me, consequently I sold them all off, fully convinced the sooner I eradicated such delicate blood from my flock the better. I am certain the Cotswold sheep would not do well on warm land and small enclosures; they require room and air. I think every person who breeds for profit should carefully consult both soil and climate, and select stock best calculated for it, without prejudice. I am not acquainted with Cornwall, but if the soil and climate is similar to the Gloucestershire Cotswold-hills, I have no doubt our Cotswold sheep would suit much better than Leicesters; they can stand more cold than any other sort, yet, like all other breeds, the better they are kept and the more care that is taken of them, the better they will do.—I am, sir, your obedient servant,

A COTSWOLD BREEDER.

Gloucestershire, Cotswold-hills, June 18, 1840.

P.S.—The gentleman your correspondent alludes to in his neighbourhood who gave a description of Cotswold sheep must be a very young man, and quite ignorant of sheep, and good management also, otherwise he would not allow such dangerous dogs to remain on his farm untrained.

ON SOILING MILCH COWS.

Sir,—You would oblige a young Farmer, if you could procure from any of your numerous Correspondents, the result of any experiments they have themselves made on Soiling Milch Cows. The information would be valuable, in proportion to the extent to which it has been tried, and also if tried in an entirely rural district. Where land lets high near towns, there is a great demand for milk: I have no doubt of the benefit of the plan, but I wish to know if any one can recommend it, who has tried it upon a large scale, for cheese or butter. We read of wonders performed in Holland, and elsewhere; one acre summering four Cows. As I have never had an opportunity of proving the truth of this assertion, I should feel particularly obliged, by your procuring some information upon the subject.

I am, your obedient servant,

TYRO.

FINLAYSON'S HARROW, AND WILKINS' BRAKE.

Sir,—In answer to the Carmarthenshire Farmer who wishes to know where Finlayson's Harrow and Wilkins' Brake are to be had, and which of those implements is the best, Finlayson's Harrow is to be had of Mr. Marychurch, Haverfordwest, who makes many of the modern implements—iron ploughs and harrows, turnip drills, with or without the apparatus, for delivering manure with the seed.

In regard to Wilkins' Brake, never having seen it, I can give no opinion of its qualities, but I can recommend Finlayson's Harrow as a powerful and efficient implement, not only for clearing the ground of couch grass and other weeds, but also for the seed earth for Spring corn, which I did in the following manner: after being ploughed, harrowed, and rolled, sow the seed on the smooth surface, then Finlayson's Harrow, followed by a light seed harrow, which will not only cover the seed in a very perfect manner, but deposit it at a regular or equal depth. The price is nine guineas.—I am, Sir, your humble servant,

June 12, 1840.

ANSWER TO QUERY AS TO THE HEAVIEST RECORDED WEIGHT OF A FAT SHEEP.

TO THE EDITOR OF THE MARK LANE EXPRESS.

Sir,—In reply to a question asked by a Correspondent in your paper of the 25th of May, I write to give you the best information in my power as to the live and dead weight of the heaviest sheep bred from the rams of my father-in-law, Mr. Richard Goord, of Milton, by the under-mentioned gentlemen. Mr. Goord's sheep have been bred in-and-in upwards of 40 years, and are called "New Kents."

Name of the Breeder.	Name of the Feeder.	Age when killed, in months.	Live weights, in pounds.	Weight of carcass without the head in pounds.	Years of Existence.
Thos. Dodd, Throwley, near Ospringe, Kent.	John Minter, Canterbury, on (Pasture) Grass only.	20	142½	142½	1834
Wm. Smart, Rainham, Sittingbourne, Kent.	Himself on Grass & Turnips.	20	260	173½	1831
Richard Goord, Milton, Sittingbourne, Kent.	Himself on Grass & Turnips.	32	298	199½	1832
Jno. Oakley, Frindsbury, Rochester, Kent.	Himself, any how fed.	20	277	190	1838

The above sheep were all exhibited at the Kent and Canterbury Cattle Show, where they obtained the first premiums in their respective classes. Mr. Oakley's wether was exhibited in Smithfield, and afterwards at Canterbury, and must have lost a few pounds in travelling. I have only further to add that Messrs. Dodd and Smart have bred strictly from Mr. Goord's rams 40 years, and that Mr. Oakley has done so 20 years, as the ewe from which his sheep was bred was purchased of Mr. Palmer, of Herne, near Canterbury, who has bred in-and-in from Mr. Goord 20 years. If your correspondent would wish any further information, I shall be pleased to render it if in my power.

I am, Sir, your obedient servant,

JAMES FULLAGEN.

Milton, Sittingbourne, June 11.

REMARKS ON MR. J. B. H. BENNETT'S "LETTERS AND OBSERVATIONS ON THE SUBJECT OF TITHE APPORTIONMENT;"

AND ALSO ON THE TITHE COMMISSIONERS' ANSWER TO THOSE "LETTERS AND OBSERVATIONS."

I have been land-valuer and agent near twenty years, and have annually valued the tithes of this parish, containing about 26,000 acres, for six years.

The subject of commutting and of apportioning tithes has often occupied my thoughts for ten years before the question was brought before parliament. The first 30 years of my life was wholly spent in the cultivation of land, at least after I was capable of handling an implement. I was not a gentleman farmer, but a working one, and it was while in this capacity, that I practically felt the injustice of the old system of tithing, and this, no doubt, set my mind to work upon the subject.

When the question came before the House of Commons my ideas upon both parts of the subject, and which are entirely distinct, (commutting and apportioning) were submitted to a Nobleman, who occupies a seat in the House, and one who is acknowledged, by every party, to be possessed of very considerable abilities, and one who never meddles with a subject he does not understand. He was pleased to say that my views upon this subject were correct ones, particularly upon that part which relates to apportioning the rent-charge. I do not say this with any ostentatious view, but to prove that I am a practical man, not a mere theorist. It is evident that Mr. Bennett is also a practical man, and upon almost every part of the subject we agree; but upon that part which relates to apportioning, or rather valuing contingencies, we differ. He even seems to have right views generally upon this, but appears to be afraid to grapple boldly with the subject. It is to this part of the subject, that my remarks chiefly apply, and I feel more anxious on it, as I find the commissioners are afraid he goes too far, while I think that the conclusion he arrives at falls short of the real meaning of the act.

Having thus cleared the way, I shall commence my work by asking, what were the objects in view, in passing the Tithe Commutation Act?

These, in my opinion were *fourfold*. 1st. The old system of tithing corn and hay, &c., was a direct tax upon industry and good cultivation. The act has, or intended to, put a stop to this. 2nd. To allay the ill feeling which existed between *tithe-owner* and *tithe-payer*, and which arose, in part, through the ignorance of the tithe-payers, and in part through the evil effects of the tax on industry and good cultivation. 3d. To prevent the total annihilation of the tithe-owner's property which was taking place in some parishes where that property chiefly consisted of corn tithe, and which arose in consequence of higher rents and profits being returned from grass land than from arable. I could name several parishes where this would have been the result if the old tithe-law had remained in force. 4th. To *equalize the burden* and to *settle the question for ever*.

It could never be the intention of the legislature, in passing the act, that any land which was *not tithe-free* should be *made so*, or nearly so, whatever way it might be cultivated or occupied. There are only

a *few words* in the *whole act* which can, by any means, have this construction put upon them, and those *few words* have different constructions put upon them by different tithe valuers. It was evidently the intention of the framers of the act, that all lands, *not tithe-free*, in every parish, or township, should be put upon an *equal footing*, according to the nature of the soil, whether occupied in grass or under arable crops. I will say that this is the only honest way of settling the question.

When the tithes of land was covered with a *fixed modus*, the law says, and very justly too, that that land is to have the *benefit* of that *modus* in apportioning the rent-charge. According to the ideas of the tithe commissioners all old grass land, although subject to corn tithe under the old tithe laws, will now, by the new act, be in the same situation as land covered with a small *modus*, and, in some cases, *tithe-free*. Now, if this had been the real intention of the framers of the act, there is little doubt but express clauses, for that purpose, similar to the clauses on *modus*, would have been inserted in the act. Such a vital principle would not have been left to the *vague construction* which might be put upon a few words.

With the general principles of the act, I have an high opinion; but in some cases it has done an injury to the tithe-owner, and in others, to the land-owner. These are evidently some omissions in the act. Suppose all the land in a township, subject only to corn tithe, has been in grass eight, or ten years previous to the passing of the act. How does the tithe-owner stand now? Why his property is gone for ever, for when there had been *no tithe for seven years*, there could be *no average*. On the other hand, when the whole of a township had been much over-ploughed for seven years ending 1835, the averages are raised above what we may call par, and the land-owners are saddled, for ever, with more than is justly due from them. I say these appear to be omissions in the act, and it is evident to me that the commissioners draw this inference from them, that each field, or each farm, or each land-owner's property, should be apportioned upon the principle which is intended, by the act, to be applied to a *whole township*. The influence which the commissioners and some tithe-valuers draw from these omissions, coupled with a wrong construction put upon a *few words* in the thirty-third clause, has done, and will do, considerable mischief in the country.

Now, inferences may be drawn from *actual clauses* in the act (not from omissions), that the commissioners and Mr. Bennett, have erroneous ideas respecting short charging old grass land *not covered*, with a *fixed modus*.

In the forty-second clause there is provision made for *change of cultivation* in *hop grounds* and *market gardens*. When old grounds are thrown out of cultivation, by this clause, the extraordinary charge shall cease to be charged, but when new grounds are appropriated to such purposes, an additional amount of rent-charge is to be put upon such land. Now, as I have before said, the framers of the act never could intend that grass land, subject to corn tithe only, should, by the act, be made *tithe-free*; and, as there is no clause providing for change of cultivation in such cases, the only fair inference is, that such grass-land should, in apportioning the rent-charge of a township, be put upon the same footing as the arable, taking the natural quality of the soil into consideration.

It is only *interest* or *caprice* in the land-owner,

or occupiers, which continues grass land *permanently* so. And ought these to have any weight in apportioning the rent-charge upon a township? If I think it more profitable to occupy land in grass, am I, on that account, to be exonerated from contributing my *fair share* to the church, or to the tithe-owner? Is my land to be made tithe-free, or nearly so, by the act? If it be, then I shall make bold to say, that the act was made upon *false principles*. Perhaps land may have been held in grass from a *vindictive feeling* in the owner, or occupier, arising from some *dispute* with the tithe-owner; from a *peevish, selfish, penurious* disposition, or from *narrow minded* sectarian views. Is a just and lawful burden to be removed off land *for ever* because the owner, or occupier, is a man of bad feelings? And is the *easy tempered* open hearted man, to be saddled *for ever* with a high rent charge, because his tenantry have over ploughed for seven years previous to the passing of the act? I admit that where the *whole* of a *township* or *parish* has been in grass, or over-ploughed, the rent-charge will be light or heavy accordingly. But in *these cases* it will be *equal*. It is in such cases that the act is faulty; and, it is evident, from the general tenour of it, that such cases were overlooked; for I firmly believe, from carefully examining the act over and over again, that those who framed it *intended* to do justice in every case.

It will be seen, that it is only in cases where one part of a parish, or township, has been *over-ploughed* and another part in *old grass, or in grass for seven years* previous to the passing of the act, that I, and the commissioners, and Mr. Bennett, differ in our opinions on the subject of apportionment.

To exhibit what I conceive the erroneous principles laid down by the tithe commissioners, and Mr. Bennett, I shall suppose several cases, and I will suppose none but what are *real ones*, of the same nature have come under my own observation.

I must first say, that nearly the whole of Mr. Bennett's arguments are in favour of my principle. They are sound, clear, well expressed, and to the point, but he is evidently *frightened* at applying them to the *extent* which he seems inclined to do. Before I proceed further, let me analyze the thirty-third clause of the act, at least all that part of it which is necessary to clear up the point in dispute. After stating that the tithe valuers are to adopt the principle of apportionment agreed upon by the landowners, the clause goes on to say, "or if no principles shall be then agreed upon for the guidance of the valuer or valuers, then, *having regard to the average titheable produce and productive quality of the lands.*" Here is a part of a sentence, or rather a parenthesis between two commas, which the commissioners, Mr. Bennett, and some tithe valuers, divide into *two distinct* parts, having *two distinct* meanings, nearly opposite in their effects upon an apportionment. The latter part of this *fraction* of a sentence is clear, and understood by all men. The former part is considered by some, to have nearly the same meaning as the latter; but if the commissioners are right in their view of it, the tithe valuers should be endowed with a sort of *second sight*, or rather he should be able to see how land is *for the future*, to be cultivated, at least for sixty or a hundred years. But then, to make this matter easy, so easy that any *old woman* might turn tithe valuer, the valuer is to jump at this conclusion; namely, that if the land has been in grass forty or fifty years it will remain in grass till the *resurrection*, consequently

have no titheable produce upon it, that is where it is only subject to corn tithe under the law; in other words it will be made *tithe free for ever*, although it was *not so* before the passing of the act. Mr. Bennett does not go so far as this, but then he touches upon the "vested right" of old grass with a very light finger. A little before, I have said I would suppose several cases to show more clearly the fallacy of ever going to the length of Mr. Bennett's "contingent" principles. But I find he has done this for me at page 6th of his "Letter and observations," in paragraphs 3d, 4th, and 5th. Here is a sort of dialogue between an *over-tillage* Clod-hopper, an *old Turf Landowner*, and a *Titheowner*. (By the by, the owners have nothing to do with apportioning the tithes.) The over tillage landowner argues *very fair and honestly*, and at last agrees for three shillings per acre, although he has been paying five shillings per acre. This is all very well, but does Mr. Bennett do the same at page 7th, in his example of apportionment there? No! But let us see how the gentleman of the "Old Turf" comes on in paragraph 4th, in page 6th. He stands up manfully for the "vested right" of his beautiful old turf. At last he agrees for *threepence per acre*, or seven shillings and sixpence for a *total exemption*, and *laughs* in his sleeve at overreaching the titheowner, as he has "*no doubt*" in his own mind, but when all contingencies are considered, his tithe is worth sixteen-pence per acre, or two pounds for being *tithe free*, which is the same thing. Men of the turf are proverbial for being sharp, and it seems old turf men are half-brothers. Now by Mr. Bennett's mode of argument here, he *acknowledges the contingent tithes*, in the case of this old turf, to be *worth sixteenpence per acre*, and yet only charges *threepence per acre*. Here he charges thirteen-pence per acre *less than he considers the tithe to be worth*, while with the arable gentleman he charges sixpence at least, but perhaps four shillings per acre *more than he considers the fair value*. This is what I call *one-sided work*, and yet it is evident that the Tithe Commissioners would have been more favourable to the old grassy gentleman. I will here state a fact.

One or two landowners in a certain township, had allowed their tenants to over plough. Another has not allowed any part of his property to be ploughed for a considerable number of years, and the land was only subject to corn, potatoe, and turnip tithes. This man claimed Mr. Bennett's contingent principle to be adopted in apportioning the rent-charge agreed upon for the township. Others backed him, because it was more favourable to them, not having much under the plough for the last ten or fifteen years. After giving my argument, for my principle, I was allowed to apportion it my own way, and when done is quite satisfactory to all parties. They feel that the burden is *equal*, although some pay *more*, and others *less* than they did before. I apportioned it on the different fields according to the *natural quality* of the land, and only applied the contingent principle to the woodland; but here I did not carry it out to the length the Commissioners, or Mr. Bennett, would have done. A case has come under my observation, of a landowner not allowing his tenants to plough, but who is lately dead. His successor will no doubt be more liberal in this respect. Now if the rent charged of the township where this property is situated, had been apportioned last year upon the Tithe Commissioners' principles, it would have been made *tithe free*; or, at the most, nearly so for ever. What has one year done? Why, over-

turned the necessity of applying the contingent principle. One short year may do this in any case. No man can live for ever. We well know that what one generation does, perhaps the next undoes. To say how land may be occupied for the next fifty years, is to talk nonsense. Agriculture has been revolutionized in my own native township twice in my time, (fifty years.) When I was a boy about one-tenth of the land was under the plough. When I was twenty-five years of age more than one-third; now about one-eighth. Look at this, and see the folly of saying that any land now in grass, will remain so for fifty years to come. Then again to talk of the beauty of old turf. No one admires it more than I do; but in apportioning tithe, we must not be led away by beauty, if we are sometimes in choosing our wives. We must do our duty, or do justice, to the toiling arable cultivator as well as to the jolly grazier.

I will now offer a few observations on Mr. Bennett's example of apportionment at page 7th, in his "Letters and observations." I consider it to be a most unfair one. All the land in grass has a *shifting* modus upon it. That is, if I understand it right, while in grass, a trifle per acre is paid, but when in corn is subject to common tithe. This shifting modus has nothing to do in the principle of apportionment; it merely forms a part of the average, or sum agreed upon between the landowners and the titheowners, in lieu of the whole township or parish. In this example of Mr. Bennett the rent-charge should have been charged upon all the lands equal, according to natural quality of the soil. The opinion of John Meadows White, Esq. in a note on the 33d clause, is in my favour respecting a shifting modus.

This clause says, "that lands shall have the full benefit of every modus and composition real, prescriptive, and customary payment, and of every exemption from, or non-liability to tithes relating to the said lands respectively, and having regard to the several tithes to which the said lands are severally liable." The meaning evidently here is, that all land when the tithes are covered with a *fixed* modus, or composition real, that modus, or fixed sum, must be charged upon *that land*, and will form the subject of a distinct apportionment from the rest of the township or parish. It is not so with a *shifting* modus; the valuer is told in this case to have "regard to the several tithes to which the said lands are liable;" of course, if liable to corn tithe, must be charged as all other lands liable to the same.

In the case of Mr. Bennett's example at page 7th, we will suppose the property of L, which is all upland turf, had been in the market ten years ago, before the Tithe Act had been thought of. And suppose Mr. Bennett had been employed by some intended purchaser to value it for him; and suppose Mr. Bennett had got the crotchet in his head that the land would never be put under the plough, and of course never subject to corn tithe. Well, he brings in his valuation with 300*l.* added to it, upon strength of this contingency. The intending purchaser would set him down for a blockhead and would have said, "I will have no such contingency considered: the land is subject to corn tithe, and I shall be ruled in the price I give accordingly."

Auctioneers, at the sales of property, always point every advantage about it in the most brilliant colours, but I will venture to say that no one of these long-tongued gentlemen, at the sale of the supposed property of L. would in stating its advantages,

have once alluded to its being tithe free, in consequence of its being old turf. If he had done so the whole company in the room would have laughed at him.

About fifteen years ago, a gentleman in my neighbourhood bought a township in a grazing district in Yorkshire, the whole of which was in old grass. One part of the estate was *tithe free*, the other part was subject to *corn tithe*, of course tithe free while in grass. I know he gave a greater number of years purchase for the tithe free land.

In the case of Mr. Bennett's example at page 7, the property of A. and that of L. would have sold ten years ago for the same sums, if the land in each property had been equal in quality, and situated in other respects the same. But if the meaning of the tithe act is as explained in this example of apportionment, and as understood by the commissioners, the property of A. is now by that act *depreciated* 300*l.*, and that of L. *increased* in value 300*l.* Did the framers of the act contemplate this? If they did, I will say they were not honest men.

But look at Mr. Bennett's mode of valuing contingencies and say whether he even values them in a fair straight-forward manner or not. On the property of A. of 120 acres, there is 100 acres under the plough (an extreme case); the corn tithe of this 100 acres he values at 20*l.* per annum; 40*l.* would be nearer the mark, but this is of no consequence for my argument, only it would have shown the *enormousness* of his principle in a more *glaring light*. On the contingency (he might have said the certainty) of a *less quantity* being ploughed, he takes 6*l.* off this 20*l.*; for in column 10th he says the *proper value* of the tithe is 14*l.*, because, he says, in the same page, that the "*probability* is, that in a few years the tithe may not be worth 10*l.* or one-half their present value; and 4*l.* less than what he calls their proper value. Now this is just as extreme a case, and more so, than that of L. where all is upland old turf. There is little doubt but Mr. Bennett is quite correct in his "probability" of the tithes of A.'s property being reduced to *one-half* their present value, whatever that might be, in a few years. Then I ask why not give him the full benefit of this *certain* "contingency" when he gives L. the full benefit of a *doubtful* one. But the unfairness of his principle does not end here, for mark—when he has gone over the parish, upon his "contingent" principle, there is a *deficiency* of 18*l.* in making up the total rent-charge for the parish. Well, he has to begin to apportion again, and how has he done this? Why to make a crooked thing straight, he makes it still more crooked. He charges A. 2*l.* 15*s.* more than the *proper value* of his tithes according to his own principle, but L. he *only* charges 4*s.* more than what he *calls* the *proper value*, but a great deal *below* what I should call the *proper value*. Therefore when the work is finished he has charged A. 16*l.* 15*s.*, or 6*l.* 15*s.* more than what the tithe really would be worth in a few years under the old law, according to his own opinion. L. he charges 1*l.* 4*s.* instead of 9*l.* 2*s.* 6*d.*, which I consider should be apportioned upon him. As I have before said he gives L. the full benefit of a *doubtful* contingency, and A. less than half the full benefit of a *certain* one.

Suppose I go over the parish along with Mr. Bennett, while making out the apportionment; as I wish to hear what he has to say as he proceeds, I will hold my tongue, as he is to apportion the tithe and not me.

Well, we go upon the property of A. first, and

in walking over it Mr. Bennett says, "Mr. A. is a hard working fellow, but certainly not a very wise one, as he is ruining his land by over ploughing, having 60 acres out of 120 *more* under the plough than he ought to have. His corn tithe is, and has been, for some years back, worth 20*l.* a year; and no doubt the tithe commissioners would charge this sum to him and his heirs for ever. I will not be quite so bad as this; my contingency principle must be put in force here. Well, when I have properly considered all these, I feel convinced, that even if he continues his present system of farming, his land will, in a few years, only produce *half the value* of crops it has donately; but he will soon see that it will be to his interest to lay a greater portion of it down to grass; I shall therefore say at once that 10*l.* a year will be a fair value for a lease which is to last till the resurrection. But what will the commissioners say, and the old turf gentlemen, if I only charge this sum; besides, Mr. A. deserves a little punishment for not having more regard to the beauties of old turf, and which produces the favourite dish of old John Bull. Well, I will charge him 14*l.* a year upon his long lease, which is *only 4*l.* more* than he ought to pay." Thus we go on till we come to the property of Mr. G., charging every one *more* upon the contingency principle than each ought to pay. Mr. G. gets a *proper sum* apportioned upon his property, as he ploughs a proper proportion. But we will proceed at once to Mr. L.'s estate. "Beautiful grass this," says Mr. Bennett. "Oh! I like to see old grass land, it puts me in mind of *Arcadia*, and it certainly smells of *roast beef*, this gentleman certainly deserves to go to heaven as cheap as possible. The commissioners, I believe, would not charge him a farthing, their veneration for old grass is so great; besides they go upon the principle that *all land* which is in old grass at *this time*, will *remain* so till the last trumpet sounds. I do not think so, but after all I do not exactly know how to act here, I cannot tell what to think about the *probability* of this beautiful grass land being ploughed up. The owner, or occupier, may die any day, and their successors may change their mode of farming either from the high price of corn or some other circumstance. Even the passing of the tithe act itself may be the cause of a change of farming, as the tithe now will *not increase* the expences of raising corn or other arable crops. He must be charged 2*d.* per acre, and I will charge his neighbour Mr. M. 1*d.* per acre. A. is charged 2*s.* 9*d.* per acre, which appears *more in the extreme*, and he is certainly placed in a *much worse situation* than either L. or M., but then he cannot see his own interest so well as these old grass gentlemen, and will be sooner reconciled to his *overcharge* than they, or the tithe commissioners to my *short charge* on the old grass. Well, I have now finished this apportionment; but how is this? I want 110*l.* off the parish, and I have only got 92*l.*, which leaves a deficiency of 18*l.*; I must have made some miscalculation, I must now begin to apportion again; and, as this is the case, I am determined to do it *honestly* this time; 18*l.* is 4*s.* in the pound on the rent-charge already apportioned; 4*s.* in the pound upon all *must be quite fair*, but yet this makes an additional charge to A. of 2*l.* 15*s.* and only 4*s.* to L. and 2*s.* to M. This does not *look right*, but it *is so* and must be so."

Mr. Bennett has now finished his apportionment, and although I considered him to come to wrong calculations, I kept my mouth shut, but

now when I am by *myself*, I can have all my *own way*, and shall therefore begin to find fault.

To be serious, if any one will read the bottom paragraph of page 7, of his "Letters and observations" they will see that *his arguments* are in favour of a more equal charge. He says A.'s charge is an *extreme one*, and that he is placed in a *worse situation* than either L. or M. "That the adjustment is *more severe* on A.'s estate than on the others, and he will eventually be the *suffering party*."

One of the principal faults of this apportionment is the apportioning the rent-charge upon each property as a *separate parish*, which is not intended by the act, except in such cases as the act provides, such as fixed moduses, &c.

At page 8, there are four examples to illustrate his opinion on apportionments. In these there is a modus of 3*d.* per acre on pasture land, but it is evidently a *shifting one*. Tithe is due from the *same land* if in corn or hay. Now this modus will only affect the *commutation*, not the *apportionment*. There are no particular fields on which the tithes are covered with a "modus, composition real, prescriptive and customary payment." The *whole* of the land is liable to *hay and corn tithe*. In these cases it is evidently the meaning of the act that the *whole land* in the parish, should be equally charged according to the natural quality of the soil; this, Mr. Bennett seems never to consider at all.

Just see the folly of his mode of proceeding. Turf more than 40 years old is called old turf, and is charged 2*d.* per acre, if *upland*, but if on a river bank 1*d.* per acre; 30 years old turf is charged 3*d.*; 20 years old 4*d.*; 10 years old 6*d.*; and 7 years old 12*d.* per acre. These charges are to be made whether the land be worth 5*s.* per acre or 50*s.* Not a word about quality. If I understand Mr. Bennett's contingent principles the valuer is to consider how the land *will in future*, be occupied, not how it *has been* in by-gone times. But it seems to be a principle laid down both by him and the commissioners that the *longer land has lain* in grass the longer it *will lie*.

But look at the difficulty of getting at the truth respecting the age of grass land; there will have to be a *jury summoned*, (no, the valuer is to be judge and jury whatever crotchet he may have got in his head) and *witnesses examined upon every field in grass*. Every landowner will endeavour to make his grass as old as possible. There will be no doubt apportionments to make 10 years after the passing of the act. Of course any sharp-sighted clodhopper, who has viewed things in the same light as Mr. Bennett, may have 10 years old grass, when the tithe comes to be apportioned, which was then in corn. "Oh!" says Mr. Bennett, "but I shall only look back from the passing of the act." Ha! my good fellow, but you also say you are to *look forward*; and in considering contingencies you *must look forward*, you have no other way to look. This clodhopper will perhaps swear that his grass is 20 years old, and that it *shall remain* in grass 100 years *after he is dead*, But just look here my good fellow, in apportioning the rent-charge upon grass land 10 years *after the passing of the act* you will want witnesses to prove that it is 50 years old before it can be called *old turf*, and charged 2*d.* or 1*d.* per acre, and 40 years old for 2*d.* per acre. A certain landowner, at no great distance from this parish, when the tithe act was in progress, gave order to his tenants to plough as little as possible,

and in the year following he had 200 acres less under the plough, upon his property, in one township. He could not tell how the tithe act would work then, but he knew that to have less land under the plough could not, by any possibility, be against, and might be in his favour.

It might be quite safe to adopt either the principles laid down by the Commissioners, or Mr. Bennett, if the apportionments were to last only 7, 14, or 21 years; but this is not the case. When once confirmed, they are to stand for ever.

At page 13, in the heading of some extracts and remarks, Mr. Bennett says that doubts have arisen whether tillage farmers are sufficiently relieved by his principle of apportionment. I do not wonder at this. I am also equally surprised that he should still adopt them after writing *any one of the paragraphs in that page. I will just take one.* "In the third place, regard is to be had to the *several tithes* to which the lands are respectively liable. These are the *express words* of the Act of Parliament. Nothing is said in this place about the tithes which the lands have produced within the *seven years prior to Christmas, 1825, or within the last seven years, or within 70 years*, but regard is to be had to the *several tithes* to which the land is liable, *whether they have produced tithes or not.* Not only one particular tithe, but every tithe to which the land is liable under *any circumstances*, is to be taken into account." This, as well as the others in the same page, breathe the true spirit of the act, but is quite at variance with his practice in his contingent tithe apportionment. His remarks at page 14 are equally in favour, with a few exceptions, of my opinions. In his concluding observations, at page 16, he nearly undoes all he has done in the several preceding pages. He appears to be like Earl Grey with the reform bill, frightened at what he has done.

I shall now make a few remarks on his principle of apportioning the rent-charge upon land of unequal value.

At page 16, in paragraph 4th from the top, he says, in speaking of inferior land, "it follows of course that the value of tithes is higher in proportion on bad land than on good. In many cases, where *poor land* is necessarily managed at a *great expense*, the tithe will amount to a sum not less than *one-third*, or even *one-half* (he might have said *the whole*) of the *landlord's rent*, and this is no uncommon thing in districts of weak corn land." He is perfectly right here, and this was one of the *gross injustices* of the old abominable system of tithing. One of the objects in passing the new act was to *put a stop* to the injustice of taking the tithe in full, from *highly cultivated land* of any description, but particularly from *highly cultivated bad land*. But does Mr. Bennett remedy the evil? No; or but very partially. He leaves a great portion of the sting behind. The old system of tithing has prevented thousands of acres of inferior land from being cultivated at all.

In his examples at page 16, he charges land with only 6s. per acre rent, at one-third, or 2s. per acre. That worth 36s., per acre is only charged one-sixth, or 6s. per acre. Now, if his meaning be that the 6s. land is only worth this from *extreme bad management* in the cultivation, and the 36s. land made of that value from *extreme good management*, then he may be right in his apportionment of the rent-charge. But if these are the *proper values* according to the *real nature of the soil* or its *capabilities*, then, I say, he is wrong in his

charging. Supposing this to be the case, I will take one acre of each value, as put down in page 16, and compare his principles with mine.

Mr. Bennett's principle.				Rothwell's principle.	
1 acre worth	6s. rent,	Tithe rent charge	s. d.		s. d.
		1-3rd or	2 0	On ditto	1 3
1 ditto ditto	12s. ditto....	ditto 1-4th	3 0	ditto	2 6
1 ditto ditto	25s. ditto....	ditto 1-5th	5 0	ditto	5 0
1 ditto ditto	36s. ditto....	ditto 1-6th	6 0	ditto	7 3
			16 0		16 0

It will be seen that, in this case, my principle is charging 4s. in the pound on the *value*, and supposing the value to be the *true value* according to the *nature* of the soil. The above are heavy charges for tithe according to the value of the land, but this makes no difference in my argument.

If, when in valuing land, for apportioning the tithe rent-charge, I come to two fields the soil of which is *exactly of the same natural quality*, I charge them the same for tithe, although one field may, from superior management and a great outlay of capital, be worth 40s. of rent, and the other only worth 10s. from *extreme bad management*. I do not spare a *lazy sloven* at the *expense* of the *industrious man*, who expends his capital freely. If I come to two fields which are both in an uncultivated state, and both worth *one price* per acre for rent in their *present state*, but, from the *nature* of the soil, or *subsoil*, one field is capable of being brought into a productive state with *less capital* than the other, I should put a greater amount of tithe rent-charge upon it. This is what I call considering its capabilities.

When the principle of apportionment is left to me I value all the land in the township, or parish, upon the above principle, and charge it accordingly; that is, when *all the land is subject to the same tithes*. I never make any difference on account of its being old turf, new turf, or arable land. "Equal burdens break no backs," and of course are easy to carry, and I have found that *every apportionment* I have made has been *satisfactory to every landowner*. My plan of valuing land for tithe requires more practical knowledge in agriculture than Mr. Bennett's plan. But when a township or parish is all valued, the dividing of the rent-charge is more simple. It is only seeing how much the *whole rent-charge* will be in the pound on the whole amount of the valuation, and dividing it upon each field at the same rate. There is neither a *deficiency* nor an *overplus*. If all the tithes of a part of the land be covered by a *fixed modus*, that forms a *distinct apportionment* from the rent of the township or parish. The modus is apportioned upon that part, and is then called the *rent-charge*, and is then subject to *variation*, by the average price of corn, like the rent-charge upon the other part of the township or parish.

Some valuers do not charge wood-lands with tithe, and others a mere nominal sum. I consider this not right. This is the only description of land which, in my opinion, contingencies ought to be considered, except land much subject to floods on the banks of rivers. If wood-land was very rough and uneven and almost unfit or impossible to convert it either into *tillage*, *meadow*, or *pasture*, if the timber was removed, I should charge it with little or no tithe. But if this was not the case I should charge it one-third, one-half, or two-thirds the amount of other land of the

same quality. Any man who has lived 50 years may have remarked a great quantity of wood-land converted into tillage, or grass, within that time. If land is *not tithe free* before the passing of the act it does not make it so, merely because timber is growing upon it.

I can name several townships where plantations have been made to a considerable extent since the tithe act was passed; and in some of these instances no tithe has been charged, and in others only 1½d. per acre charged, where the average of the township is 2s. 3d. In one instance, part of the land was under arable cultivation at that time. If the commissioners and some valuers are right in their principles, in such cases any landowner by merely planting his land with forest trees *before the tithe be apportioned*, may free his land from tithe for ever. And this may be done for less than 20s. per acre with seedling forest trees.

There is another bad feature in this light charging, or not charging, old turf and wood-land. The greatest, and of course, the wealthiest landowners receive most of the benefit; of course, the burden is thus thrown upon the *smaller and poorer*. These seldom cultivate their land with an eye to beauty, or for a future generation, for this very plain reason, they cannot afford it. They endeavour to make the most of the land in *their time*, consequently they seldom have much wood-land and as seldom any *old turf*. Thus, all the woodlands, demesnes, parks, gardens, and pleasure-grounds of the rich, some of which is not occupied in any useful purpose in a national point of view, are exonerated from contributing their due share to the church; while, at the same time, the *wealthy owners* have all the church patronage, and have nearly the *whole management* of all the money expended upon it. Should any one but just name church reform, they will immediately call out that "the church is in danger" and rise up in defence of what they call their "vested rights"; when, at the same time, they pay less than their *due share* to its support. In a township where I have lately apportioned the tithe rent-charge, there is a considerable quantity of *old turf*, some of it *upland*, and some very excellent, on the banks of a river. Another portion of the township belonging to three landowners, has been rather hard ploughed. When the tithe came to be apportioned, the landowners could not agree upon the principle, and had meeting after meeting for this purpose. The old turf men defended the "vested rights" of old turf manfully with a mere handful of troops; that is, with a very few words in the 33rd clause of the act, namely, "having regard to the average tithable produce." The remaining part of the sentence would not do, but which were brought forward by the other party, and held up to them like the "shield of brawn to the Jew." Neither party would give way, when, at the last meeting, I, as valuer, was called in to give my opinion. I did so, with a few of the arguments I have given in this paper, after which there was only one who voted for the "vested rights" of old turf and wood-land. When I took my apportionment in, even he expressed his satisfaction with it, and the principle it had been made on.

One part of this township will show the absurdity of saying that because land is *old turf* it will remain so for even 50 years. This part, and which is part of the *river land*, was, about 30 year ago, *old turf, prime meadow, and pasture*; land of all others which few people would have expected to be put under the plough. About 20 or 25 years ago, the

occupiers were changed, and, I believe, the ownership. Since then it has been under a regular course of cropping, and has had a good farmer upon one part of it, who, I have little doubt, but has paid 10s. per acre for tithe, or at least it has been worth that per annum, taking the whole farm together. Now if the tithe of this township had been apportioned 30 years ago, upon the principle laid down by the tithe commissioners, this land would have been made tithe free. If my friend, Mr. Bennett, had apportioned the tithe he would have charged it 1d. or 2d. per acre. Mine will average about 3s. 1d. per acre. If he, or the commissioners, had apportioned it at *this time*, from 7s. to 10s. would, most likely, have been charged. I ask, would an apportionment upon either principle have been an honest one? If it had been made, at either period, for only seven years, then in one case the "vested right" of old turf might have been held sacred, and in the other case, an extra charge might have been made. But this is not the case, when once apportioned it is to stand.

Wherever there is a burden hanging over land, although it be prospective, and to all appearance at a considerable distance, that burden will affect the price of that land when in the market. It is ridiculous to suppose that 1s. 3d., 2s. 6d., or 5s. per acre, would be the *fee simple value* of the contingent tithes upon old rich turf, subject to corn, potatoe, and turnip tithes, even if wool, lambs, calves, colts, pigs, and geese, raised upon that venerable old turf, were not subject to tithe. I will venture to say that any man would give 3 or 4l. per acre more for old turf to have it completely free of tithes or arable crops, except he had a prospect of an apportionment made by Mr. Bennett, or the commissioners.

It will be seen that my principle of apportioning tithe is this. That when the sum is agreed upon by the titheowners and landowners of a township or parish, I apportion it equally upon all the land in the township or parish, according to the nature of the soil; that is if *all the lands* are subject to the same tithes.

Every apportionment in this part of the country made upon my principle has given satisfaction (if the valuer understood his business and were honest) even to those landowners who had a great portion of old turf; while *every one, without a single exception*, which has been made upon other principles, have not given satisfaction, either to the owners or occupiers of land.

To the honour of the landowners in South Lancashire, at least to all those with whom I have come in contact, and with whom I have had any conversation upon the subject, have acknowledged that no other principle can be a fair one, and, from the construction of the act, is that intended by the legislature when it was passed.

I hope there is nothing in the above remarks which can be considered in any way disrespectful to the tithe commissioners, for it is my desire, in every case, to pay them due deference. I have always seen in them a desire to do right, and this has prompted me to give my opinions, although I am but a humble individual.

I am, sir, yours respectfully,
Winwick, June 15, 1840. W. ROTHWELL.

Diarrhoea is proving very fatal this season to young calves; but the following treatment has proved very successful:—As soon as the disease is ascertained, use gentle bleeding, and mild purgatives, such as 2oz. of prepared chalk, 1 dram of opium, 4 drams of catechu, and two drams of ginger, mixed and divided into three parts, given at ten hours' interval.

ON CULTIVATION.

TO THE EDITOR OF THE FARMER'S MAGAZINE.

SIR,—I should esteem it a favor if you would insert the following mode of the cultivation of land, in the hope that if there is any improvement to be made, some of your readers will be kind enough to comment upon it.

The land is of a mixed soil, and cultivated after the manner of the 5th course.

Fallow 1st.—Plough it twice before Christmas, then baulk the stretches and bring it on to the flat, then plough it on the great stretch across twice, draw it out on 8ths, stretch it up, muck it about 11 loads per acre on the stretch, and then plough (the muck in) it again on the stretch, with the necessary harrowing and rolling. Sow 3 pints of turnip-seed per acre on or about the 21st June, and hoe them twice.

Barley, 2nd.—Plough the turnip land on the stretch, clean baulk it across, and then on the stretch again, sow it of barley three bushels per acre, hoe it and keep it clean; sow one peck an acre of small seeds.

Clover, 3rd.—Weed it, and the average crop is 25 cwt. to 30.

Wheat, 4th.—Muck on to the clover ley for this, and get it in 2 bushels an acre, about November. Plough once, roll it in the spring, never feed it off, hoe it.

Barley, Oats, or Peas, 5th.—For oats, I plough but once, and put in 3 bushels an acre; peas the same; but for barley I case it about three times.

Dibbling I find the best mode of depositing seed, and as cheap as any, because the seed saved will defray the extra expense incurred by dibbling. I have tried nitre and find it act remarkably well on the soft corns, but cannot see so great an effect upon the wheat. I sowed about one cwt. an acre; I have also tried it upon turnips, and will report with what success I meet. I think if farmers were generally to plough their lands intended for fallow twice before Christmas, it would spare the expense of the hoe materially; and I am the more induced to say this because as Mr. Reed justly observed in your valuable Journal of January last, that "all soils contain more or less the principle of vegetation, and when any part of this power is employed in the production of weeds, there is just so much abstracted or taken from that which should be employed in raising corn."

By inserting the above you will oblige,

A YOUNG FARMER.

Great Chesterford, Essex, June 20th, 1840.

ANSWER TO QUERY.

[FROM A CORRESPONDENT.]

In the last week's *Mark Lane Express* a query appears, to ask how much butter weekly can be produced from one cow; if you choose to reply as follows, you may.

A labourer of mine has a cow kept by me as part of his yearly wages, which, after her third calf, produced 18lbs. of butter per week, which gradually decreased until within a fortnight of calving again, at which time she gave nearly 8lbs., and never was entirely dry for calving. She has had the epidemic, and is now recovered, and in full profit, but not equal to last year.

June 25.

G. B.

QUERIES ON THE FAILURE OF THE CLOVER PLANT.

SIR,—We, in this part of the country, have annually to lament the entire failure of red clover plants in our pastures of the second year: now the fact of red clover remaining permanent for a longer period, upon lighter and warmer soils, induces the hope, that by proper care and cultivation, a variety may be obtained, capable of retaining its hold upon the soil, during the whole period that we pasture our lands, which seldom exceeds two years.

With that view I take the liberty of proposing the following questions, in the hope that some of your readers practically acquainted with the growing of clover and other seeds, will favour me with answers to them through the medium of your inestimable Journal.

Is it not a fact that by judicious care and cultivation we have the power of modifying, to an almost indefinite extent, the character and nature of plants, not only as respects the luxuriance of their growth and the quality of their seeds, but also, in many cases, as regards the permanency of the hold which they retain of the soil? Thus if the seeds of perennial rye-grass be saved for a series of seasons, in the second year of its growth, will it not in consequence lose its perennial character? Now are not the seeds of red clover usually saved in the second year of the plant's growth? And supposing that it were a triennial, would not this have the effect of making it a triennial plant? Are the seeds of red clover ever saved in the third year of the plant's growth? And if so, have the lands saved in that manure, been tested against seeds saved in the usual way, with a view to ascertain the permanent character of each respectively? In "*Hortus Woburniensis*," I find perennial red clover strongly recommended for cultivation in alternate husbandry: is it so cultivated in any part of England?

Your insertion of the above questions will oblige a former correspondent.

J. R.

East Lothian, 17th June.

ON COW MANURE.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—In reply to the letter from a tenant farmer of Bangor, near Wrexham, North Wales, in your journal of the 18th inst., I should recommend him to mix horse manure in an equal proportion with his cow manure; by that means he will give a stimulating property to the cow manure which it does not possess in a great degree by itself, being naturally of a cooling nature; it would make his grass as abundant again, and prevent the cow manure crusting so much, as it would be parted by the horse manure, from turning it several times before laying it on the land; or try another method, mix lime along with the cow manure. Lime is invaluable as a top-dressing for meadows, it would kill the moss and decompose the manure, so as to make it serviceable for the nourishment of the grasses. As chalk is used on retentive clayey soils, to render them porous, and makethem work easier for the plough, I should think from analogy that adhesive stuff like cow manure, would be reduced by a sufficient quantity of lime being mixed along with it, so as to prevent it caking after being spread.

If your correspondent should benefit by these hints, I should be happy to hear of it through your journal.

I am, Sir, your obedient servant,

A YOUNG KENTISH FARMER.

ON THE USE OF COW MANURE.

TO THE EDITOR OF THE FARMER'S MAGAZINE.

SIR,—Being a constant reader of your magazine, I observe at page 37 in your number for this month, a letter from a Tenant Farmer, on the use of cow manure as a top-dressing for grass land. Being an occupier of a few acres of grass land only, and a keeper of a few cows, I have for some years practised the following method with my cow dung. In the spring I cart it to the field and mix in alternate layers of cow dung, horse dung, coal ashes, (finely sifted) with as much night soil as I can conveniently get, in the proportion of two-thirds cow dung and one of horse dung, and also what pig manure I may have by me, or can get at a convenient distance and price, and in about two months, turn it over and well mix, and again do so a short time before it is spread on the land, which I do if there is a prospect of wet weather immediately after the hay is got off the land, if not I let it remain until the Autumn after the grass is all eat off, when it is well spread and dressed in; more especially in the summer, which I have found to answer well, having had more than two tons of good dry hay for two successive years per acre at each cutting. By this mode of treatment, if a few wood ashes were added to the above, it would be all the better. I have found that horse dung, and cow dung mixed, works more kindly and better than either separately. If you think that the above will be of any use to your Bangor correspondent, and it is worthy insertion in the magazine, you are at liberty so to do, if not commit it to the flames.

I am Sir, your obedient servant,

Wakefield, July 3.

G. STRAFFORD.

CORN LAWS.

The following very curious letter, which was written in 1610, by Lord De Roos, was communicated by the Duke of Rutland to the Walsham Agricultural Association, in October last, at a meeting over which his Grace presided;—

"Sir,—I doubt not but by this time you are very deep in the faculty of law-making. I desire much that if any laws be past, we may have the heads of them; the titles of the chiefest.

"I had some conference with Sir R. Buller concerning a bill, that no corn should be imported until it came to some extraordinary price. Of this having some consideration, there seem to me many reasons very strong for the converting of this bill into a statute.

"A first is, because the importation of corn is an exportation of money; and that, even in case of necessity, is a hurt to the commonwealth, though then tolerable for the avoiding of a greater hurt, but in unnecessary cases altogether inexcusable.

"Secondly, if importation be unlimitedly allowed, the cheapness of corn will take away the benefit of husbandry; and the benefit being taken away, husbandry itself (which is usually undertaken for benefit) will decay, and if husbandry decay, there are likely to grow two main inconveniences: the one, that the poor must starve for want of work, the effect whereof hath too much appeared in the conversion of tillage into sheep pasture; a second, that in short time this kingdom, to be set to a rent, will be less worth per annum many thousand pounds. For I think within this twenty years husbandry hath in many places doubled the yearly value of land, which, if tillage decay, is likely to return to the ancient meanness.

"And whereas there is a seeming objection that importation makes cheapness, and cheapness seems to favour the poor, I affirm that importation will especially

hurt the poor, and for their sakes especially it is to be forbidden; for if corn be cheap, and the poor man have no money, what avails it to him that corn is cheap when he cannot buy it? If money be carried out of the country, and the poor man be not set on work by reason of the decay of tillage, I wonder how he shall buy this cheap corn without money? I think it were better that corn were for 7s. a bushel, and yet by reason of tillage the poor man should earn 18l. or 2s. a week, than corn being at 5s. he should earn 12d., or perchance nothing. For, without question, half of the work at least will be abated. Besides, there are two inconveniences at this time which accompany cheapness, and make it unprofitable to the poorest sort of men. The one is the wickedness of bakers, of whom I hear it reported, that at this time they make their bread after 10s. the bushel; a second, of the town merchants, who buy ship-loads of corn, and sell it so much under the ordinary price as may serve to undo the husbandman, and yet so near the price that the poor hath far less benefit by it than the commonwealth, yea, themselves have harm.

"Thus I have expressed to you the considerations which have entered into my thoughts upon this business, which, if you think them worth the mentioning, I pray you to communicate to Sir Buller, which I do not to add to better judgments, but rather to submit them to their approbation. And I wish that this letter may be prevented by a statute before it comes to your hands.

"And so wishing you the direction of the Highest, and that the hand of the Almighty may be with you all unto the making of laws wholesome, and restorative for this poor and sinful land, I take leave, ever resting yours most assuredly to be commanded,

"F. ROUS (De Roos).

"To my loving and much esteemed cousin,
Richard Carey, Esq., of London."

ON ERADICATING CHICKWEED AND COLTSFOOT.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—It would very much serve me, and doubtless many others, if, by inserting in your valuable paper this letter, you could procure some information on the best means of eradicating chickweed and coltsfoot; or, as it is here called, *spunk*, with which my land is very much infested: though I plough deeply, and weed the land before and after the crop is in the ground as well as I am able, it is not possible to stir the chickweed in a corn crop after it is above the ground without pulling up the crop with it; and it appears equally impracticable to pull up the coltsfoot, it sends its roots so very deep into the soil, and even into the subsoil. Your serving me in this will much oblige, Sir, your most obedient servant,

A SUBSCRIBER.

Dublin, May 28.

THE COLTSFOOT.

SIR,—One of your correspondents, a few weeks since, enquired the best method of extirpating Coltsfoot (*Tussilago Farfara*) from arable land. He gave it also the provincial name of *spunk*. The flowers should be gathered from the beds several times, as often as any can be found, to prevent fresh seeding the land: it flowers in February, March, and April, and before any leaves appear: this system must be persevered in through the whole course of cropping, and when the field is fallowed the same precaution is necessary, or the seed will be shed upon the land before ploughing, and thus secure a plentiful crop for the whole of the next course. The plant itself can hardly be got rid of without a summer fallow.

Framlingham, July 2.

GEORGE EDWARDS.

CHELMSFORD WOOL FAIR.

This fair took place on Tuesday, June 30, and the quantity of wool offered for sale, and the numerous attendance of the gentry and of the farmers, showed its growing importance to the agriculturists of the county. The quantity in the market was considerably larger than at any former fair. The following is the official statement, combining a comparison with last year:—

Fleeces shown in samples	16,452
Weighted	3,567
Number of Fleeces on show and weighed in 1839	20,019
1839	14,710

Increase for 1840 5,309
The gross weight of that weighed was 122 cwt. 3 qrs. 15 lbs.

The prices obtained were rather below the late quotations, but were upon the whole, perhaps, as good as the unfavourable circumstances of the trade warranted the growers in anticipating. The following is the average on the business of the day:—

Half-bred and down hoggets	15½
Ewes	12½
Wethers	13

On referring back we find that the following were the averages of the three previous fairs:—

1839	Hogget 18d. Ewe 16d.
1838	Hogget 20d. Ewe 16d.
1837 (a year of great depression in the trade)	Hogget 18d. Ewe 9d.

The dealers present were Messrs. Johns, Legg, Bell, Unwin, Elkington, &c.

THE DINNER.

At three o'clock, about 170 gentlemen sat down to an excellent dinner, served up by Mr. Lake, of the Saracen's Head Inn, in the county-room, at the shire-hall. J. Disney, Esq., the President of the Society, took the chair, supported by Lord Rayleigh and the High Sheriff. There were also present—J. Bullock, C. C. Parker, J. Guillemaude, J. O. Parker, T. Ellman, H. Wyatt, T. Brewitt, and J. Burness, Esqrs.; Capt. McHardy; Revds. T. Brooksby and W. Shepherd; Messrs. C. Matson, C. Legge, J. Brewitt, S. Baker, H. Boys, W. Hicks, D. Scratten, T. G. Ward, J. Brewster, T. Mayott, J. Page, E. Fulford, — Burder, T. Gale, W. Gale, W. F. Hobbs, J. Shepherd, W. May, B. Hobbs, G. Hart, — Hart, T. Addy, T. Durrant, — Seabrook, R. Baker, W. Crush, J. Smith, T. and W. Johns, — Elkington, J. Blyth, — Unwin, C. Hurrell, R. Seabrook, J. W. Downes, C. Hilton, T. Crooks, &c. &c.

After the cloth was removed, the usual toasts were drunk,

The PRESIDENT said they had 16,000 or 18,000 fleeces to sell, and he hoped some gentleman would make an offer. (*Calls for Mr. Parker.*)

Mr. C. C. PARKER said, having been called on he rose to make an offer. He did not know whether *Bell's Weekly Messenger* was any guide, but in it he that morning saw south-down hogget wool quoted at 1s. 6d., and ewe wool at 15d.; whether that told the truth he could not say, but as they ought to have something to guide them, he would offer his wool at that price. (*Cheers.*)

The PRESIDENT said, he had to offer for Mr. John Brewitt about 700 fleeces of Kent ewe and tegs at 15d. The offer was declined.

The PRESIDENT offered on behalf of Mr. Hutley 1,600 long-wool hoggets, at 17d., and 900 short-wool ewes, at 18d., to Mr. Legge and the rest of the buyers.

Mr. LEGGE said he was obliged to Mr. Hutley, but he was sorry he could not give that price.

The PRESIDENT said, he was desired by Mr. Malden to offer 350 Kent ewes and 200 Kent hoggets to Mr. Legge at 15½d.

Mr. SHEPHERD said, he was happy to state that he had sold his wool to Mr. Johns. As the agricultural interest was flourishing he thought they ought to give the trade a turn; and he had sold his teg wool at 15d., and his ewe at 12½d. (*Cheers.*)

The PRESIDENT said, Mr. T. Crooks had desired him to offer 400 superior half-bred Leicesters, and 250 down tegs, 250 down ewes, and 100 half-bred Leicester ewes, the hogget at 16d., and the ewe at 13d., to Mr. Legge.

Mr. LEGGE—I am extremely obliged to him, and I regret it is not in my power to receive it at his price.

The PRESIDENT said, Mr. Malden had made an offer, and had not received an answer to it.

Mr. LEGGE said he would give Mr. Malden 14½d., that was the best price he could offer.

Mr. MALDEN said he could not accept it.

The PRESIDENT said Mr. Carter offered to Mr. Legge 300 Down tegs at 1s. 4d., and 280 Down ewes at 1s. 1d.; if Mr. Legge refused them they were open to any other buyer.

Mr. LEGGE said trade was in such a state that he could not possibly take it at that price.

The PRESIDENT said, Mr. Harvey had requested him to offer to Mr. Unwin 900 half-bred Leicester tegs and 250 Down tegs at 15½d.

Mr. UNWIN said he would accept them. (*Cheers.*)

Mr. TOWER said before dinner he had offered his wool to Mr. Johns, and he would repeat the offer now: it consisted of Merino-Leicester and Merino-Saxon fleeces, part of 1839, and he asked 16d., 15d., and 14d. for them.

Mr. JOHNS said the 16d. and the 14d. he would give, and for the other he offered 1s.

Mr. TOWER said he did not make the offer before, because he would not bring Saxon into competition with South-down; but when he heard the sum given by Mr. Unwin he thought he was entitled to do so. There was only a penny between them in 239 fleeces, and they must divide that.

Mr. JOHNS said Mr. Tower misunderstood him—he offered 1s. for the lot for which he asked 15d.

Mr. TOWER said he could not take that.

No further offers for wool were made in the room, and the company broke up about seven o'clock.

SALES OF WOOL.

The following is a detail of all the sales of wool effected, as extracted from the official returns:—

BOUGHT BY MESSRS. BELL AND SON.

Fleeces.		Fleeces.	
Mr. John Smith	250	Mr. Andrews	84
— M. Mason	103	— Perry	1645
— Surrey	140	— Steele	190
— S. Reeve, sen.	115	— Jas. Clarke	145
— S. Reeve, jun.	150	— Bright	210
— C. Low	109	— Bernard	270
— S. Low	54	— G. Carter	580

Total fleeces		2554

BY MR. CYRUS LEGGE.

.. T. Tower, Esq.	87 fleeces of Merino Leicester Cheviot	14
	229 do. Merino Saxon, of which 90 were tegs, indifferently washed ..	15
	250 ditto, well washed ..	18
W. and H. Marriage	204 ewe fleeces	13
Mr. Thos. Mayott, Burstead ..	181 fleeces	
Mr. J. Wright	331 ditto	
Mr. Cleve	390 ditto	
Mr. Malden	450 ditto	

BY MR. ELKINGTON.

Mr. Christy, Broomfield	204 Down tegs and ewes	
The following showed, but, we believe, did not sell:—		
Mr. T. Mee, Great Burstead ..	112 fleeces	
Mr. J. Marriage, jun., Moulsham Lodge	252 ditto	
C. C. Parker, Esq.	215 ditto	
Mr. W. Crush, Chignell	100 ditto	
Mr. Reeve, Writtle	115 ditto	
Mr. J. W. Addy, of Rolleston, Writtle, prior to the fair, sold to Mr. Archer, of Bishop Stortford, 700 tegs, at 1s. 3d., and 500 Down ewes 1s. 1d.		

FLY IN SHEEP.

SIR,—In reply to the "Nottinghamshire Farmer" respecting *tar* as the application he used on his sheep for the fly, he asks three questions, neither of which I am prepared to answer. But I would strongly recommend his using the "sheep dipping composition," prepared only by Mr. Thomas Bigg, 15, Crawford Street, Portman Square, London. Having used it now for some years, I, as well as many others, can give testimony to its efficacy and usefulness, if properly applied. I have dipped in August 2000 sheep, and have only had but one struck with fly, occasioned by scouring. Another great benefit he will find is that the sheep that have been dipped will be grazing in the hottest weather, whilst those that have not been dipped will be in the shade, or where there is no shade will be together in large groups terrified with flies. He may think it too much trouble perhaps, but if only he once begins to dip, I am certain he will not leave it off. Yours, respectfully,

A KENTISH FARMER.

Eastchurch, Isle of Sheppy, July 3.

TITHES.

SIR,—I observe in a cotemporary Journal the following remarks relative to the "Bill to exempt stock in trade from being assessed to the poor-rates."

"Though we fully agree in the policy of exempting stock in trade, and personal property from being assessed to the poor-rate, we cannot help regretting that the present opportunity has been lost of introducing some provision for rectifying the hardship of rating tithes according to the rule recently laid down by the court, in the *Queen v. Capel*."

"As regards tithes the rating of them upon the same principle as lands and hereditaments are rated, must be admitted to be a hardship. A landlord receives his rent as absolute property; it is his own without any labour or service. Such lay property may belong to minors, married women, persons bedridden, lunatics, and others altogether incapable of rendering any equivalent; whilst the tithe-owner, if an ecclesiastical person, claims his tithes or his rent-charge, as a compensation for his clerical services."

Now surely the necessity of employing this unlucky *if* is sufficient to upset the argument altogether, since if those services are not to be performed, there can be no reason why the tithes should not be rated in similar proportion to the land itself, and no one, it is to be presumed, would make a distinction in the rating of tithes, whether the same should be vested in the church, or in lay impropriation. Moreover it is not fair to couple the tithe-owner with the land-owner, but rather let the corn-grower and the tithe-gatherer go hand in hand, although the distinction may not be very material. Theoretically, the landlord may be said to pay the poor-rates, but practically, the money comes out of the pocket of the husbandman or tenant of the soil, and no one will venture to assert that he does not perform, or render an equivalent in labour and attention.

The determination of the question in the case of the *Queen v. Capel*, has relieved the valuers under the parochial assessment act of much perplexity and indecision; I happen to be one of that number, and unless arguments more conclusive than any which I have hitherto heard, can be adduced in support of the tithe-owner's claim to undue abatement from the rent-charge in making the assessment, I shall hold it equitable that as the tithe-owner had the actual amount of the parochial rates (payable in respect to those tithes) added to his composition (as determined by the average of seven years previous to 1835) in order to liquidate similar parochial claims in future, so a valuation of the land itself (as well as the rent-charge upon that land) ought to be founded upon the price of grain during that period, and not upon the improved value of land at the present moment, arising out of fortuitious circumstances which the chances of seasons or the malignity of men may entirely subvert. I should say, as the gross estimated rental of land in a parish is to the net value thereof, so is the whole amount of the rent-charge to the sum at which it ought to be assessed. Now whether we take this rule as our guide—whether we take the amount of rates paid in respect of tithes during the period before alluded to, adding 5 per cent. for contingencies and the trouble of collecting the rent-charge, and deduct these from the gross amount—or whether we deduct 15 per cent. in one sum, the assessment will, in most cases, come out nearly the same.

I remain, Sir, yours very truly,

Dilham, July 1, 1840.

W. NORFOLK.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—Being a constant reader of your inestimable Journal, I am always gratified in perusing any useful piece of information communicated through that channel, whether given editorially, by a single-handed correspondent, or, perhaps in not a worse way, from a little sound friendly argument proceeding from two parties, the last-named being undoubtedly the best, and no doubt would be even more resorted to, on many occasions, when knotty points in agriculture became a matter of dispute, were it not for the unpleasant feelings which but too often arise between the parties, by each thinking his own way right: it is matter of regret that such is the case, seeing that many inexperienced agriculturists might profit from a friendly discussion even in a public journal.

My reason for troubling you at this time, is owing to a correspondence I have lately seen, between a Mr. Kinmouth, somewhere resident in Armagh, and a Mr. Gardiner, in the county of Ayr, on the subject (and a most important one, too) of drainage of land: whether parallel tile-drains, or transverse stone-drains, are the most beneficial, economical, or permanent? Now it is almost in vain for me to say, living in Ayrshire as I do, that I decidedly approve of the system of parallel tile-drains, and can, with safety, say, that what Mr. Gardiner has already published on the matter, is the uniform opinion of the most enlightened agriculturists of this great and flourishing county, the experience of half a century having proven, beyond all doubt, that collateral or transverse drains, filled to a necessary depth with stones, may help to relieve the land of superabundant moisture for a few years; but such would never be resorted to now by any man, in his right senses, that wished his land thoroughly and permanently drained. Mr. Kinmouth, no doubt, from seeing that he had the worst of the argument, has very prudently withdrawn from the field, not, however, without grossly insulting Mr. Gardiner, by doubting the veracity of his statements, which Mr. G. has resented, perhaps rather keenly, still I consider him justified, as no man of any feeling can, or should, remain silent, after having his word doubted in a public journal; or, undoubtedly, guilt will be the construction put upon it by the public mind.

In a later number of your Journal, I have observed a most malevolent, vindictive, but at the same time unmeaning, attack on Mr. G., by some snappish scribbler, signing himself S. B., Newry, in which he makes a mighty fuss about two lines having been wrongly quoted from "Hudibras" by Mr. G.; as if all his argument could be upset by that single circumstance. Now I, who have never read "Hudibras," nor any work of so little utility at the present day, have seen the lines quoted the self-same way over and over again; but now, thanks to this immaculate virtuoso, shall be able to detect and correct them, should they come under my notice again. Exulting at this wonderful discovery, he sincerely says, that ignorance and error he has always found to be twin brothers: well, granting this to be the case, we shall just see before leaving S. B. whether he cannot be foiled with his own weapons. He then goes on blaming Mr. G. for putting a wrong construction on Mr. Kinmouth's sentiments, and endeavouring to mystify their proper sense: now I deny that; as no man whatever, taking his words in their literal

sense, could have put S. B.'s construction on them, without some exposition of the matter, which goes far to disprove his own words, viz., that "both writers were unknown to" him. He then very frankly offers his own opinion on draining, and labours hard to prove what every enlightened agriculturist well knows to be the sentiments of our ancestors, now no more, who flourished in the century immediately preceding the one in which we live; and loudly denounces (to him) the unwelcome sound of real lasting improvement. Alas! for poor afflicted Ireland, if all her sons were like this unhappy S. B.! Luckily, there are many who hold different views from this son of the good old times, as is amply verified, by so many of the influential youth of Ireland annually visiting and residing in our county for a time, to learn the most approved modes of husbandry; and by so many of our native Scotch being called upon to act as bailiffs, stewards, &c., to the Irish nobility and gentry. Poor S. B. does not wish to hear any thing of the matter, but, like the hedge-hog, coiled up in his prickly skin, spits his venom on all who would gladly assist him to what he does not know. Deeply read in ancient history, he knows the year, nay, I suppose the very day, and by whom, the foundations of the pyramids of Egypt were laid? In a word, what is it that this modern Socrates does not know? One word more to S. B., and I have done with him; let him be perfectly sure that he is right himself, before attempting to put others right: let him go to school and learn his multiplication table, and "don't be after telling us," that one million of drain-tiles is *exactly* the one-hundredth part of what would be sufficient to drain 400,000 acres, at 3000 to the acre! "Ignorance and error," says S. B., "are twin brothers," so if the cap fits, just let him wear it. Excuse the length of this letter, and by publishing it, oblige Sir, your very obedient servant,
Ayr, June 29, 1840. R. B.

QUERIES ON DRAINING.

SIR,—I take the liberty, through the medium of your Journal, of requesting an answer to the following questions, and which I trust some of your numerous agricultural readers acquainted with the subject will answer:—

How does wood answer as a bottom or sole for tiles, in draining pure moss? What thickness ought the boards to be made, if they answer? What depth is the best to cut moss drains? And also, how wide ought the drains to be from each other? Having commenced draining about thirty acres of pure moss, I find that the tiles do not answer without a sole, and the moss is so soft in many places that slates sink unequally. I am preparing boards of from 10 ft. to 15 ft. in length, by half an inch thick; but before doing so to any great extent, I would feel obliged by any of your readers, who have a knowledge of moss-draining, giving me the benefit of their experience. It may be as well to mention that the moss is level, and nearly six feet deep of moss, without fall sufficient to allow the drains to be cut to the bottom of the moss, although they can be cut four feet.

I hope you will permit a corner of your paper for these queries, and will much oblige,

Sir, your most obedient servant,

A FARMER NORTH OF THE TWEED.

CULTURE OF THE CAMBRIDGE-SHIRE FENS.

In the preface to Part II. of Vol. LI. of the *Transactions of the Society*, noticing Mr. Glynn's paper "On Draining the Fens in Cambridgeshire and Lincolnshire by steam-engines," a conjecture is hazarded, that "the time is probably not far distant when all the fen-lands in the kingdom shall be enabled to exert their native exuberant fertility." So far as the fens of the *Bedford Level* are concerned, this conjecture is being rapidly verified; the more complete and certain system of drainage by means of the steam-engine, as well as the great improvement of the outfall, having enabled the occupiers of the land to avail themselves of the valuable strata of clay and marl, which are now accessible at a very short depth from the surface, and by which a new and most advantageous system of farming has been introduced.

As some account of this new method may be interesting to such members of the Society as are acquainted with agricultural pursuits, I have endeavoured to collect some information on the subject, which I now with great deference submit to the Society.

The practice of using clay and marl upon fen or moss land in other parts of the kingdom, especially in Scotland, has been in use for many years, and their good effect has been fully appreciated; as may be seen in Mr. Steel's excellent work on the subject;* the mode of practice laid down there, however, being somewhat different from that in use here, it will not preclude any benefit which may be derived from such information as I have been able to obtain.

The soil of the fens is a dark-coloured, almost black, peat, mixed with silt, and graduates downwards into spongy peat. In many places occurs a tenacious soapy-feeling peat, mixed with micaceous sand, in which state it obtains the local name of *bear's-muck* forming a barren untractable soil, which, by drying, becomes of a stony hardness. The peat in some parts rests on a thick stratum of blue calcareous clay, called *gault*:† but, in other parts, a deposit of gravel, varying in thickness, is found between the peat and the gault.

The great Bedford Level contains upwards of 300,000 acres, which formerly were subject to continual floods, so that the cultivation of the land was exceedingly uncertain; and, at best, it could only be worked in spring and summer. The usual course of husbandry was to pare and burn the sod, as a preparation for coleseed or rape, which was fed off by sheep, and was followed by one or two successive crops of oats, according to circumstances; and was then laid down to grass for two or three years, when it was again broken up, and the same routine of crops observed. The crops, of course, varied according to the situation of the land: where it was very low and wet, the oats rarely exceeded four or five quarters per acre, and were light in quality; but in more

favourable situations, where the land was higher and stronger, the crop would be from five to eight, or even ten, quarters per acre: all this, however, depended upon the state of the land, as to being flooded or not. Fifty years ago, the drainage was very inefficient.

The outfall for the waters having been much improved by forming the *Eau Brink Cut*; by scouring out and deepening the Hundred-foot River, which communicates with the Eau Brink, and conveys the upland waters of the river Ouse more directly to sea; also, by scouring out and deepening the river Nene and other main drains, and by the introduction of the steam-engine, the drainage has been so complete, that the land is now esteemed almost *certain* from being injured by floods: the consequence of this has been a new system of farming, and the general introduction of wheat crops, and the practice of *claying or marling the land*. This complete drainage has enabled the farmers to dig for these earths with success; and the benefit arising from their being laid on the land, is as great as that effected on the light sand lands of Norfolk, and by the same means.

Where formerly an uncertain crop of very inferior oats was grown, and in many cases left on the ground, the farmers being unable to get them off from the rise of the waters; now, from the use of clay, they grow excellent crops of *wheat* and of oats of a very superior quality. The land is also much improved and kept in heart by the *manure* they are now enabled to put upon it; for formerly a *fen* farmer never thought of using manure, which, indeed, he could not often get upon the land if he were inclined so to do. Instead of the former course of pare and burn for coleseed, and then oats, oats and grass, the present mode is, in the first instance, to pare and burn for coleseed, then oats, *wheat*, *clover*, *wheat*, and *fallow for coleseed*, with occasionally a crop of beans, which is exceedingly productive; so that the old mode of paring and burning every five or six years is now very generally going out of use where the lands are clayed. Another advantage from this new mode is found in the land being less obnoxious to the ravages of the *wire-worm*: where the fen-land has not been clayed, and at the same time lies dry (*drummy*), the wire-worm abounds to the serious injury of the farmer; but it has been found that the worm does not so much infest the land where it is made heavier, and more consolidated, by the clay.

The mode of claying the land is as follows:—

Trenches are formed the length of the piece of land, 7 feet long, and 30 inches wide at the surface:—they are dug sloping down to the clay, where they are 8 feet long by 4 feet wide; the clay is taken out *two spits* deep, of about 14 inches each, and thrown on the land on either side. When the first trench is finished, another is begun, and so on, leaving a heading between each trench of from 20 to 36 inches. When the line of trenches is completed, another is commenced at the distance of from 12 to 20 yards, according to the quantity of clay intended to be laid on the land; but the general quantity is about 200 cubic yards per acre. A pit of the dimensions above stated, viz., 8 feet by 4 feet, and 2 spits of 14 inches, or 2 feet 4 inches, will contain 74 feet 8 inches, or about 2½ yards.

The depth at which the clay is found varies considerably: in some places it is touched by the plough, and so on from 2, 3, to 8 feet. The

* "The Natural and Agricultural History of Peat Moss, or Turf Bog." By Andrew Steel, Esq. Edinburgh, 1826. Lang and Black.

† A fair sample of gault was found to contain 33·7 per cent. of carbonate of lime: the carbonic acid given off from it by the action of acids, had nearly the same kind of unpleasant odour as that from fetid limestone or swinestone.

expense per acre of course varies according to the depth of the pit, and the quantity laid on the land, from 50s. to 70s. A very great advantage attending this mode is the saving of expense, *no horses and carts being required*. From the peculiar nature of the fen earth, these trenches are soon ploughed in, and no traces left of them.

It has been stated that the course of cropping on these clayed lands is very different from what it was before claylag. In addition, it may be observed that the growth of vegetable crops, such as mangel wurzel, potatoes, &c., is much increased.

GEO. AIKIN.

December 1838.

IMPORTANCE OF AN AGRICULTURAL EDUCATION.

The following article is from the last number of the *Schoolmaster's Magazine*, a publication which does honour to the north of Ireland. The observations we deem extremely appropriate, and if acted on, Ireland would shortly be different from what she is :—

"Agriculture requires a very considerable degree of intellectual knowledge; and hence civilization and refinement always accompany superior cultivation. It is indispensably necessary for the successful farmer to know the particular season in which the different seeds should be sown and planted, and also the particular kinds of soil congenial to the different kinds of grain. He would require to know the manner of treating each to the greatest advantage, with the least possible expense—to ascertain what kind of crop will generally produce the greatest profits without impoverishing the soil—and what changes may be necessary, even on the same field, so that the ground may not 'run out' (as the farmers express it). As connected with agriculture, it is necessary that the labourer should be very well acquainted with the excellences and defects of the different breeds of cattle—the best method of rearing and employing them to good advantage—the different diseases to which they are liable, and the most efficient means of curing them. These he should study on scientific principles, assisted by the dictates of experience. Such are some of the important studies to which the agriculturist who would successfully cultivate the earth should direct his special attention; and such a pursuit is by no means unworthy even in persons who rank in the highest stations of society. It was held in much esteem by the Romans, and one of their greatest generals, Cincinnatus, was called from the cultivation of the farm to command the armies of the commonwealth, and to direct the affairs of the state with absolute rule and authority. In modern times it engaged the royal attention of George the Third, who devoted himself to it with unwearied zeal. The Emperor of China annually ploughs a furrow, holding the plough with his own hands, in order to engage attention to this art among the most ennobled of his subjects. As agriculture is, at least nominally, held in high estimation among all civilized nations, it should not be entrusted entirely to the hands of ignorant individuals who can scarcely read and write, and whose ignorance would render them the slaves of ignorant, of vulgar prejudices. No; it should be placed under

the guidance of persons competent and willing to prepare themselves for a scientific discharge of the duties required. We have a variety of schools and colleges for the instruction of pupils in medicine, law, architecture, and other arts and sciences, and is it not truly astonishing that an occupation, on which not only the existence of every individual depends, but all the comforts and conveniences of life, is left almost exclusively in the hands of un instructed persons, who must, of course, follow the beaten track which custom has marked out for their direction, because they have neither mental power, knowledge, nor confidence sufficient to venture beyond it; and for the poor farmer to hazard experiments without sufficient reason to anticipate a profitable result would, in the present age, be extremely imprudent. It is not for us at present to say whether emigration should be encouraged or not, but this we broadly assert, that if our lands were properly cultivated, we could support a much greater population. In our best laboured districts an ingenious agriculturist could perceive much to be improved, owing to the neglect of draining, &c., in the improper application of particular plants to uncongenial soils, or in the waste grounds, almost, if not entirely useless. The immense produce which the earth is capable of yielding is almost past conception. Every improvement in agriculture is followed by greater luxuriance; and if persons were properly educated for the profession, and societies encouraged for the dissemination of agricultural information, as is the case with all the liberal arts, a given portion of ground could be rendered capable of supporting in comfort and comparative independence a much greater number of individuals than at present. This would, to a considerable extent, remove two great evils that afflict our country—poverty and crime, as idleness has been found to be the parent of vice and misery. It is well known that much good has been effected by the enterprise and experiments of comparatively uneducated agriculturists; and of what immense value would it be, if agricultural schools were established throughout our land, under the management of well-qualified professors, who would give suitable instruction on all branches of science necessary to the man who would become a successful agriculturist! A course of varied experiments could be adopted by these different institutions, and a copy of these modes could be transferred to each, stating the results, whether favourable or the contrary. Thus the heavy loss of ignorant speculators in husbandry would be avoided, both to the persons themselves and to the community. It might be well, at the outset, to have small text books for the mere tyro in farming, explaining the proper season for planting the different kinds of grain, the average quantity of seed required for each, in proportion to the ground sown and the manner of cultivating each. Indeed, such a book might be read alternately in all good schools, to much advantage. In public seminaries the lessons could be exemplified on the farm. We confess we have only glanced at the happy consequences that might result from such schools; and we now ask, why does not government encourage such institutions? The additional produce in the neighbourhood of such schools would be very considerable, and other farmers would, by imitation, carry out the plans to an amazing extent. Add to this the advantage of young men, after having become fully acquainted with the subject, both in theory and practice, spreading themselves over the land, with ability

and zeal for carrying into effect their superior information. Let not the ploughman toil in ignorance—elevate his mind with knowledge, so that he may not labour in vain—enlarge his understanding, that he may have a source of enjoyment in pleasing meditation, “while whistling o’er the furrowed land.”

ON TURNIP CULTURE.

TO THE EDITOR OF THE DUMFRIESSHIRE AND GALLOWAY HERALD.

SIR,—I have little of what is termed “a turnip soil,” and have been obliged to raise the crop mostly on a cold clay; yet my experience leads me to the belief that on such soils, where they can be thoroughly *drained* and well wrought, turnip crops may be raised scarcely inferior to those on freer soils. My crops have always been as good as any in the district. Heavy close-bottomed soils, in such wet seasons as the last, must be expected to produce light bulbs. I had a remarkable proof of this. Part of my turnips were on a high and rather flat ground, where surface water commonly lodged, and to take away which I had cut an under-drain through the middle of it. In autumn, both the bulbs and tops were less on that part, than on the rest of the field; but, on examining it, my curiosity was much excited by observing what at some distance appeared a *green dyke* winding through the middle of it. On nearer inspection, I found it nothing more than a crooked stripe of *huge turnips*, which kept by no one drill, but exactly followed the line of the *drain*. This almost made me convert to “subsoil ploughing.” I sold the crop of that field to a sheep-farmer for four guineas per acre; and though he did not bring his ewes to the field till the end of February last, when more than half the crop was destroyed by frost, still he had feeding for about 4d. weekly per head.

On such soils my maxims are—1. Clean and pulverise the soil as well as possible. 2. Form the stitches as *ebb* as possible. 3. Give a fair quantity (say 30 carts) of *well-prepared* dung, carefully spread. 4. Cover it in immediately, and as *lightly* as possible. 5. If the top of the drills are cloddy or uneven, go over them gently with an iron-toothed rake, and lay the stones and clods between the drills; one attentive woman will thus go over almost two acres in a day, hence the expense is trifling. 6. Give, at the *very least*, 5lb. of seed per Scotch acre; and, *above all things, take care that the seed is kept near the top, and lightly covered*: very little that is sown deeper than a quarter of an inch will grow.

Experience might long ago have taught the farmer, that turnip seed will germinate *only* in favourable circumstances. If the covering is so deep or close as to prevent the free access of air, germination will not be perfected, and the embryo will die. The seed contains very little to support the embryo plant; hence the plant is rendered dependent on the soil as soon as the seed-blade is formed. If the soil is poor, the plant will slowly push its root towards the manure, and can make almost no progress till it has reached it. If the dung has been covered *deep*, the plants will be so long in seed-blade that the turnip-beetle (or fly) will destroy them.

To-day, I saw some garden turnips whose bulbs were about the size of a boy's marble, but whose

tap roots must have been more than six inches long—this was owing to the gardener covering the dung too deeply.

On heavy soils, I find the lightest rollers of the turnip machine are injurious, by consolidating the soil too much. I, every year, find that the seed sown by the hand, in the old way, gives more than double the number of plants which arise from the same quantity of seed put in by the machine. Sowing by the hand costs about double the expense of machine sowing, and is not easy practicable on a large scale. But the crops shew its decided superiority, and this fact demonstrates the importance of sowing and covering the seed very lightly.

Four years ago, when I ordered my servants to give at least five pounds to the acre, I was laughed at, and told that two pounds were ample abundance. I stated that I meant to give the fly a hearty feast, and yet leave myself a good crop. By following this rule, I never need to sow more than once, and this gives my crop the advantage of some weeks' growth over those who, by sowing deep and sparingly at first, need to sow the same ground twice or thrice, have more labour than I have, and in the end require more seed. In 1838 and 1839, I was thinning out, while some farmers were sowing the third time.

An opinion prevails, that bones bring turnips sooner into rough leaf than dung does. I believe the difference is entirely owing to the *management*. The dung is often ill prepared, and commonly laid deep, while the bones are put near the seed. But, were bones put as far from the seed as the dung usually is, they would give later plants than the dung does. I had a proof of this in 1837. Part of the field was then sown with dung and bones, part with dung alone, and part with bones alone. I gave 20 carts dung per Scotch acre to the first lot, covered dung slightly, sowed 20 bushels bones per acre above this covering, and covered the whole. My servant, in my absence, gave 35 carts dung to the acre, and exhausted my stock. I gave no bones to this lot, and 40 bushels alone per acre to the third lot. The soil of all the three lots was very similar—a thin and rather free clay-gravel. The superiority of the first lot over the second was barely perceptible; but the inferiority of the third lot was most manifest during the whole season. The second and third lots were sown on the same day; yet the boned ground appeared full two weeks later than the ground which had dung alone. A similar gradation appeared in the following grass crop.

Now, Sir, I have exceeded your limits, and if any of your more intelligent farmers find fault with this, let them be so kind as show us the better way; for I like to see you, now and then, have some “scrap for the farmer.”—Yours, &c.

7th July, 1840.

G.

TO THE EDITOR OF THE FARMER'S MAGAZINE.

SIR,—I should esteem it a favour of some person who is a judge of a draught horse's conformation, would, through the medium of your very valuable publication, describe the *parts*, and what the different variations of these parts are liable to, form, position, and development; also what are the consequences of these variations. By inserting this in your next journal, you will for ever oblige your obedient servant,

Drogheda, April 20.

A CONSTANT READER.

ON FOLDING SHEEP.

BY THE LATE JOHN ELLMAN, ESQ. OF
GLYNDE, FROM A LETTER TO SIR JOHN
SINCLAIR.

I am not so far an advocate for folding, as to think it right in all situations; particularly in small inclosures, where driving the sheep to and from fold, might materially injure them, and destroy a great deal of grass, by trampling on it. I am ready to acknowledge, that a great number of sheep might be kept on a given space of land, divided into small inclosures, by laying them in small parcels, than if kept together in one flock and fold. Acknowledging this, does not prove, that folding, in other situations, has not its advantages, particularly in an open country. In such an open situation there is not the same injury done, by treading down the grass, as in small fields: but on the contrary, the farmer is enabled to manure such part of his farm as he may think proper, particularly that which lies at a distance from the farm-yard, and which seldom, if ever, has the dung cart going on it. Mr. Young observes in his Annals, "I believe, the reason why farmers are such warm advocates for folding, arises from the power it gives them of sacrificing the grass land to the arable." This I do not agree to, as, on many farms, the sheep are supported more from the arable, than the grass land, and often folded on the latter. Taking the sheep off their feed to lodge in the night, we think of great use, as it prevents dropping their soil on the pasture (what our shepherds here term *stenching* their food), which we look upon as of great use at the time when we are feeding our sheep on tares, clover, turnips, or any artificial food. I always caution the shepherd, as soon as the sheep have done feeding, to drive them off immediately, and not let them lie down, or stop to soil their food. Some shepherds are not so careful: in such cases, I observe the sheep never eat clean. I believe few animals (indeed, I know of none, except swine), which like to feed where they drop their soil, and it is fair to suppose, that the All-wise Disposer of events has so ordered, that the brute creation should be endowed with that degree of instinct which enables them to refuse such food as is not wholesome. This we have an opportunity of ascertaining, when we fold on the grass lands. The sheep always refuse the first shoot of grass after folding, and will not take it while they can get any other; and, if obliged to feed on it, it is certain to cause the flux. Another advantage arising from folding, is keeping the sheep confined in the fold, particularly in the autumn, till the hoar frost and heavy dews are gone off the grass, which prevents the disorder here called the red-water, and which in some places is called the blood or white water; in fact the dropsy.

This disorder I believe most sheep are liable to, and is caused by taking into the stomach too great a quantity of fluid. Many other reasons might be advanced in support of folding; but I hope what has been stated is sufficient to prove that the practice has some merit. And now I beg leave to state the *quantum* and value of folding.

Just 20 Southdown sheep (if a larger sheep, a less number will do) will fold one rood or rick per night; 3200 will fold one English acre per night. We value the manure at from 35s. to 50s. per acre; the goodness of which depends much on how the sheep are kept; if kept on artificial food, such

as tares, rape, clover, turnips, &c., they will drop more soil than if fed on grass only. Supposing we estimate the folding at 40s. per acre, it will amount per year to 4s. 6½d. per sheep, 22½. 16s. 3c. per hundred, or per thousand 223½. 2s. 6d.. This calculation is made, supposing the sheep are folded through the year. If it is a breeding flock, it might be well to omit folding for five or six weeks immediately after lambing, as the young lambs might suffer from being trampled upon, and from driving to and from fold, would often lose their dams, and suffer in that way more than if they remained quiet.

I have often disputed the practice of folding with the late Mr. Bakewell, who always, to make use of his phrase, said, "It was robbing of Peter to pay Paul;" and there we stopped. But if I had not to boast of bringing that truly celebrated breeder over to my opinion, I can say, that no argument I ever heard him, or any other person advance, in the least altered mine.

ON THE CULTIVATION OF POTATOES FROM THE SEED.

BY W. BUCHANAN, ESQ., OF CHALK LODGE, NEAR
CHESHUNT.

Having been anxious for some years to obtain new varieties of the potato from seed, that being of course the only way of procuring them, and having succeeded in obtaining several which are very excellent, I shall be happy if I may be allowed to call the attention of the Society to the subject, and by that means diffuse the advantages to be expected from resorting to the same means of cultivation. The ready means of continuing a variety by cuttings, is probably the reason why so little improvement has been attempted; but when it is recollected that hardness, flavour, fruitfulness, and several other qualities, are most to be improved by reference to the seeds, and that every vegetable degenerates if that is neglected, I shall have no need to name other advantages. The accompanying specimens are each from the second year's produce of single seeds: they have not been selected, but taken as they were placed in rows for winter preservation, from many others of probably equal value; for when they were raised in October, all which did not appear desirable were rejected. The seeds had been sown in April 1836, and kept in shelter, but without heat. When about an inch in height, they were transplanted into separate pots; and in May were put into the open ground, at two feet distance. In October they were dug, and only the most fruitful, or best-shaped, were retained, many having from fifty to seventy at a single root; these were taken care of for the winter, and the accompanying specimens are of the past year's (1837) produce. It will be apparent, from their size and abundance, that reference to the seeds is a ready and valuable process; and it may be expected that, by continuing it, a variety will be obtained sufficiently hardy to bear our climate. The increased abundance of several of the varieties is very great; and from the seeds of some of these seedlings which have been preserved, and accompany them, greatly improved kinds are reasonably to be expected. The seeds are to be obtained from the berry by

washing, and being dried; in the third year, any careful grower will have enough, of the kind most suitable to his wishes and his soil, to plant more than an acre; and that point is now strongly urged, as the difficulty of obtaining them, in sufficient quantity and time, has been a reason with some for not attending to it.

W. BUCHANAN.

Jan. 6, 1838.

Accompanying the above paper were a small parcel of potato-seeds and a few samples of nine varieties of potato.

The samples sent, being only two years from the seed, were, as might be expected, of small size; and the committee not being able to form any correct judgment of them in their then state, and not having a sufficient quantity to make any experiments, recommended to the Society to prevail, if possible, on some member of the Society to grow them, and to report the result. The recommendation was adopted, and Mr. Williamson took charge of one set of the samples, and Mr. H. Roberts of another set.

Mr. Williamson entrusted his samples to Mr. Hixon, a market-gardener, who grew them in some rich ground in Battersea Marsh, each plant being two and a-half feet apart. The potatoes were planted whole, and were taken up at the usual time. The produce was divided into *wares* and *chats*, the former being the technical term for those potatoes which are of saleable size; the latter, for those small or under-sized ones which are only given to the pigs:—

No. 1 yielded 30 wares and 10 chats; being a large produce, and apparently of good quality, only the wares are small.

No. 2 yielded 0 wares and 27 chats, unsaleable, and of bad quality.

No. 3 yielded 5 good wares and 3 chats. They ripened early, and seem to be the best of the whole parcel. All Mr. Hixon's professional neighbours agree respecting the probable excellence of this sort.

No. 4 yielded 15 wares and 19 chats; is a good-skinned potato, and probably of good quality, though not equal to the preceding.

No. 5 yielded 0 wares and 139 chats. The haulm was very luxuriant, and the potatoes were not ripe when taken up, though the haulm had been destroyed by the frost. It appears to be a late, but probably very productive variety, better fitted for cultivation in Cornwall or in the Channel Islands, than in those parts of the country which are liable to autumnal frosts.

No. 6 yielded 0 wares and 58 chats, which look very unpromising.

No. 7 yielded 10 wares and 3 chats, all of which are more or less tubercular, and probably not of good quality.

No. 8 yielded 12 wares and 0 chats, and appear to be of very good quality.

No. 9 yielded 1 ware, and 30 chats no larger than marbles, but which seem to be of good quality.

Mr. Roberts's samples were planted in March, in a soil rather poor and gravelly, and inclined to wet. They yielded very differently in point of size, and were by no means prolific:—

No. 2 are small, but somewhat better than the same variety grown by Mr. Hixon.

No. 3 are smaller than the above, but apparently of nearly the same quality.

No. 5 of middling quality, but very good size.

No. 6 are larger, and of better quality than Mr. Hixon's.

No. 7 are good sized, and seemingly of good quality.

No. 9 were not ripe when taken up, but were of middling quality and saleable size.

It was resolved to continue the experiments for another year, when the potatoes may be considered as having arrived at their respective degrees of perfection.

ON FEEDING SHEEP ON TARES.

SIR,—Can any of your correspondents or intelligent readers inform the public through the medium of your widely circulated magazine, as to the feeding sheep on tares?

1. What number of sheep can be fed on a 10 acre field of tares.

2. What is the condition of sheep fed on tares in comparison with sheep fed on grass or turnips? We want some crop for a four-course shift, which may take the place of turnips, which soon sicken the soil if repeated every four years; and tares appear to me the most likely substitute. Any other practical information on the sowing and feeding off of tares will oblige many who are labouring under the disadvantage of not being able to procure that correct information which ought to be afforded by our agricultural Societies through experimental farmers. Yours,

June 15, 1840.

A NORTHERN.

TANNER'S BARK AS MANURE.

SIR,—One of your correspondents asks, of what value as a manure, bark, after having been used for tanning, is considered to be? My opinion is founded on a trial, and I think, if the bark can be had for the leading, and is to be found at about a mile distant, it would pay the expense of use. It ought to be put in and spread over the yards in October, and the cattle should be allowed to travel upon it all winter, the dung, &c., making it much more valuable. There ought to be a tank near the yards, and the liquid manure ought to be pumped over the bark, &c., as often as possible.

Beware of using bark fresh out of the tan-pit; it will destroy vegetation. My neighbours spread it under their gooseberry trees in order to prevent weeds growing, and thus save the expense of cleaning.

Your obedient servant,
I. K.

ON THE USE OF NITRE.

SIR,—A great deal has been written lately on nitrate of soda as a fertilizer for corn and grass; but not a word, that I have seen, has been said whether it is a good manure for turnips. I have proved it decidedly good for the crops beforementioned, and should be glad to know if any of your correspondents have tried it for the latter, what quantity has been applied, in what way, whether drilled or sown broadcast, and what has been the result? An answer to these queries from some practical agriculturist will very much oblige,

A subscriber to your paper,
E. A. NICHOLSON,

Breford St. Martin, Salisbury, July 2nd.

REVIEWS.

PRACTICAL FARMING AND GRAZING;

By C. HILLYARD.

The third edition of this very useful practical work has just appeared, embellished with an engraving of the North Devon ox, fed by the author, which gained the gold medal, as the best beast in any class at the Smithfield Show in December, 1838, and also the first prize in the third class. Considerable additions have been made to the present work; many useful recipes are given for curing diseases of stock, and for dipping and marking sheep, and not the least valuable part of the book is a table containing the weight of cattle by measurement, to which is added the proportion of live and dead weights, and a table containing the measurement, and the computed, the estimated, and the butcher's weight, of the principal fat animals that obtained the chief prizes at the Smithfield shows for ten years past. The general remarks of the author on grazing, the breeding and rearing of stock, are valuable, as they are derived from a long and successful practice, and he has been well known as an eminent judge in that branch of husbandry. The directions and observations on arable farming are equally valuable and applicable truths, stamped by the seal of experience and of time, the great teachers and the primary ingredients in the wisdom of men. In the cultivation of Swedish turnips, and of mangel-wurzel, the author very much excels, and from personal inspection we are justified in saying that, if the "drills were straight," as Mr. H. very good-humouredly remarks, the crops exhibit a specimen almost of the "ne plus ultra" of root farming, or what learned writers call the "ideal," or the highest state of perfection our minds can contemplate. The extraneous matter and addenda contain the author's opinions and observations on the corn laws, the poor-law amendment act, rural polity, and on ecclesiastical matters, on which, and on similar subjects, he has taken a part, and shown an active and benevolent mind. We can safely recommend this practical work as containing much useful matter, and many valuable facts for reference, to all persons engaged in cultivation, who will always require such facts to be at hand, and to compare opinions and practices.

FARMERS' ASSISTANT AND READY-RECKONER.—By J. McDERMENT, Land Surveyor, Ayr. Second edition, improved and greatly enlarged.

Ayr: J. Dick.

The second edition of this very useful work has just appeared, and several valuable additions have been made, which cannot fail to render it still more useful to the class for whose purpose it was intended. The first part contains the prices of land in quantities from 1 perch to 1 acre, at prices varying from 5s. to 22s. 3d. per acre. The second division includes the most common parts of land surveying, tables of different measures converted, and of manuring drills in heaps at different distances at a rate of cubic yards of dung to an acre, and a very useful table of the number of tiles required to drain an acre at parallel distances of ten to thirty feet, and another containing the number of plants required on an acre of land from one to thirty-six feet distant. The third part contains the measurement of hay-stacks, of various forms, periods of standing, and the modes of computing the area, and of allowance in stones by the cubic yard, are very distinctly stated by the author, who seems to have paid much attention to this part of the book—very often a point of considerable importance. The mode is also given of computing the capacity of a waggon, and of dung-hills and heaps of stones, in cubic yards. The

last part contains tables of the weight by measurement of cattle and pigs, and we have had opportunities of ascertaining that no more correct method has yet been found than that of the author, differing from experiments of the actual weight by a few pounds only. The whole book is admirably adapted to the use of all persons engaged in country business—to farmers, land-agents, and valuers, who will have an opportunity of comparing and verifying their own modes of calculation, and of ascertaining the customs of similar professions. The price is small, and the size of the book convenient, and we have seldom seen an equal quantity of useful and varied matter so well arranged in a small compass.

ILLUSTRATIONS OF THE BREEDS OF THE DOMESTIC ANIMALS.

By DAVID LOW, Esq., J. R. S. R.

London: Longman and Co.

The third part of the illustrations of our breeds of domestic animals has been published, containing the "Hog," with a drawing of the wild boar and sow from Portugal; of a Siamese sow and pigs; of a sow of the old English breed, and one of the Berkshire breed.

The character and habits of the wild boar are very neatly described by the author, who has bestowed much labour and research in the letter-press part of the illustrations, and has accompanied the drawing of each animal with many excellent practical remarks. In many countries the wild boar forms an interesting animal for the chase; and for the much more useful purpose of food for the human race, no quadruped has been more extensively spread over the globe, or is capable of more general adaptation. The flesh of the wild boar when domesticated and fed in this country is very palatable, the hams are a rare dainty; and a cross with some of our smaller breeds has produced a quality of flesh equally tender and more firm than any of our kinds for pork. Several curious breeds of swine have been found in Africa and in the South Seas, of which a very interesting account is here given. Crosses with the Chinese breeds have been much in fashion, chiefly for roast pigs and delicate meat, but the author very justly doubts the further extension of the practice, or with the Neapolitan hog for the same purpose. The drawing of the old English sow and the Berkshire show admirable specimens of the effects of art, in deriving from these originals our present improved breeds. The aptitude of the hog in receiving alterations is wonderful, so that every county, almost every parish, has now a separate breed of that animal. The size has been much reduced to suit the taste of large towns, and in doing so there has been sacrificed, as usual with other animals, the mixture of fat with the muscular fibre, the property of fecundity and of nursing numerous progeny. For bacon, a large sized animal is indispensable, and for finer purposes we have now many excellent small breed. The Berkshire breed we have always regarded as our best for general purposes, in combining useful size and quality. The drawing here given of the old breed shows the straight back, round carcass, and square form, broad chest, and short neck, which forms the points of excellence of the present day. It would be desirable to get rid of the black colour in the present breed, for we think that of all colours the white is most agreeable to taste in all animals, as pigs and poultry, where the skin is allowed to remain in cooking. This publication will add a valuable portion

to our knowledge of live stock; the drawings are correct to nature, and finely executed; the paper and the letter-press are of first-rate quality; and the descriptions of the animals given by the author are alike interesting and valuable to the practical man and the amateur. No labour or expence have been spared by the parties concerned in making the publication worthy of notice, and it cannot fail to find its way into the library of every person who breeds stock, and who wishes to know what has been done, and may draw hints for the future.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

CAMBRIDGE MEETING,

MONDAY, July 13.—The town began to fill in the latter end of the week preceding the show, the Duke of Richmond, Earl Spencer, and several members of the council, having come down from London early to aid in the completion of the arrangements, and very high prices were demanded for beds, and stable-room for horses. A guinea a night for a bed, and half that sum for accommodation for a horse were very general demands; and this drove a great number to the outskirts and to the neighbouring towns and villages, so that those who made high charges in many instances over-reached themselves, and their rooms were left unoccupied.

This day was appropriated to the reception and classing of the stock, a great quantity of which arrived from Liverpool, Herefordshire, Notts., Beds., Norfolk, and other distant parts, as well as the adjacent counties of Essex, Herts., and Suffolk.

TUESDAY, JULY 14.—The Cattle-yard was not opened to the public to-day, the judges being engaged in examining the stock and in settling the awards.

At an early hour this morning the great mass of persons drawn hither from all parts of England to attend the meeting, were up and on the *qui vive* to join the throng, which in vehicles of all sorts, from the carriage-and-four to the humble chaise-cart, were crowding to witness the trial of agricultural implements, at Mr. Emson's barn, and in Mr. Grain's field on the Hills'-road. By ten o'clock there were neither horse nor any machine on two wheels left in the town. The roads leading to the different places where the trials were to take place presented a most attractive sight. At a little past ten the trial of agricultural implements commenced, pursuant to a programme which had been previously issued. Near the field where this was going on, on the premises of Mr. Emson and Mr. Grain, threshing and dressing machines, chaff-cutting machines, &c., were at work; and at a little distance in a large field (also the property of Mr. Grain) a most interesting spectacle presented itself in the ploughing match. Fifty ploughs started, and as the object was not to reach the goal soonest, but to reach it by the shortest and most even line, the individual interest excited by

each competitor was maintained throughout. The multitude of people on this spot was very large, and the number of horsemen galloping to and fro, the carriages filled with ladies and gentlemen, and the cheerful influence of an unusually fine day, created a scene which we have seldom seen surpassed.

There were no prizes for ploughing originally offered by the Society, but a number of gentlemen being desirous that while the principal cultivators of the soil were competing in the production of stock, testing the different varieties of seeds, and bringing the implements of their calling to greater perfection, there should be a little rivalry amongst the labourers, subscribed for this purpose. The result was highly honourable to Essex, the first prize being carried off by a servant of that venerable patron of Agriculture, Lord Western, and several others also found their way into that county.

The match took place in a field about two miles from Cambridge, on the Newmarket road, and we were highly gratified to see such thousands congregate to witness and encourage the labourers of England. Pedestrians and horsemen lined the road, the lordly carriage swept along to the point of action, and the scene itself was worthy of the gathering. There were no fewer than 50 competitors; the work, on the whole, was extremely well executed. The ploughing was completed shortly after one o'clock, and the prizes were distributed in the field at half-past two. A circle of carriages, horsemen, and pedestrians was formed in front of the Committee's tent, in which the ploughmen were collected, and the Noble President, the Duke of Richmond, ascended a waggon to present the rewards.

The Noble Duke, addressing the ploughmen, said—Though I am not connected with this county, either as a proprietor or a resident, yet the gentlemen and the farmers have deputed to me the gratifying task of giving you the rewards of industry and skill. It is most gratifying to me to find them thus come forward to reward the honest and meritorious labourers; it shows that they have a good opinion of you, and I have no doubt it will be your endeavour to deserve it. (*Cheers.*) I need not tell you what advantage it is that the land-owners, the land-occupiers, and the labourers of the country, should be all in close union one with another—(*cheers*)—and so long as that continues to exist this country will be flourishing, independent, and free, because it will deserve to be so. (*Cheers.*) Now I have great gratification in rewarding you, and in particular two young men, brothers, who have gained premiums, and bear excellent characters, which shows that they have been well brought up, and that they not only obey the laws of their country, but do not forget the great laws of their Creator. (*Cheers.*) I understand it is not the first premium one of them has gained, and I am quite sure I only express the feelings of those by whom I am surrounded when I say I hope it may not be the last; for we wish to encourage the labourers when they are deserving of it. (*Cheers.*)

The following prizes were then distributed:—

FIRST CLASS—SWING PLOUGHS.

1st prize, 5*l.*—to William Sutton, Kelvedon, Essex; in the employ of Lord Western.—Used Bentall's plough.

THE DUKE OF RICHMOND.—As I am not a Cambridge man, I am not unwilling to see this prize go into

K

Essex; but I dare say some gentlemen would have liked to keep it here.

2nd, 4l.—John Stammers, Coggeshall, Essex; in the employ of Mr. W. F. Hobbs.—Hayward's plough.

3rd, 3l.—George Thorn, Chesterton; in the employ of Mr. Warboy.

4th, 2l.—William Snow, of Radwinter, Essex; in the employ of Mr. Giblin.

5th, 1l.—George Bull, of Earl's Colne, Essex; in the employ of Mr. Hobbs, sen.

SECOND CLASS—WHEEL PLOUGHS.

1st prize, 5l.—James Scovell, of Babraham, in the employ of Mr. S. Webb. Used Ransome's plough.

2nd, 4l.—John Salmon, of West Wrating, in the employ of Mr. E. Frost.

3rd, 3l.—James Stiff, of Babraham, in the employ of Mr. Jonas Webb.

4th, 2l.—Edward Hall, Arkesden, in the employ of Mr. E. Hurrell.

5th, 1l.—Henry Beasteat, West Wrating, in the employ of Mr. Teverson.

The Judges in this class recommended 1l. to John Sharman, and 1l. to James Greenhill.

THIRD CLASS, BOYS—SWING PLOUGHS.

1st prize, 4l.—Daniel Smart, Saffron Walden, in the employ of Mr. M. Nockolds.

2nd, 3l.—George Giblin, Chisball, in the employ of Mr. Warboy.

3rd, 2l.—C. Marshall, Saffron Walden, in the employ of Mr. Clark.

FOURTH CLASS, BOYS—WHEEL PLOUGHS.

1st prize, 4l.—Thomas Salmon, West Wrating, in the employ of Mr. Thomas Frost.

2nd, 3l.—J. Smith, Littlebury, in the employ of Mr. Clayden.

3rd, 1l.—This was awarded to a youth named Poulter, only 15 years of age.

Each unsuccessful competitor received 2s. 6d.

The Duke of Richmond said if ever he had the good fortune to meet them again, he trusted he should find they had not forgotten what had occurred that day, and that they would take it as a proof that their masters were anxious for their welfare and comfort. (*Cheers.*)

Mr. BEWSHER then proposed three cheers for the Duke of Richmond, which were heartily given.

The Duke of Richmond returned thanks, and said this was not the first time he had found an assembly too grateful to persons enjoying the privilege of his station for what little they could do; but he assured them he should always do his utmost to join together all classes of society. (*Cheers.*)

The Marquis of Downshire said, before the assembly separated, there was a meritorious class of men whom the Committee were desirous should be marked with proper respect—a class the most valuable, to which they the agriculturists of the three kingdoms were greatly indebted—the labouring class, the peasantry of England, the men who ploughed their land to enable them to reap the fruits of it. (*Cheers.*) He proposed three cheers for the labourers of England.

Three hearty cheers were given, and the company separated.

Throughout the morning, while the ploughing was going on, a number of improved agricultural implements and machines were in operation in a field adjoining, and excited considerable attention from the gentlemen and agriculturists present: of them we may enumerate thrashing machines for horse and manual labour, by Messrs. Ransome, of Ipswich, and

Garrett, of Leiston; horse and hand chaff-cutters, by the same makers; Salter's winnowing machine; a Rack-leath subsoil plough, made by Messrs. Ransome; a light land subsoil plough by the same makers; an improved subsoil plough, made under the direction of Mr. W. H. Hobbs, of Marks Hall, and a Deanston subsoil plough; drop drills, by W. Grounsell, of Louth, and Hornsby, of Spilaby; single and double ploughs, by Palmer, of Reading; Biddell's Scarifier, and harrow; a curious machine for dibbling, by Mr. Wedlake, of Horchurch and an American plough, presented by His Grace the Duke of Richmond to the Royal Agricultural Society, &c.

The agricultural implements and machines which were tried of the Messrs. Ransome's manufacture, were subsoil and cleaning ploughs, a light double furrow plough, and two cultivators, the one Biddell's scarifier, the other Biddell's extirpating harrow. These implements severally performed their work well, and it was not a little amusing to observe the eagerness of interest with which they were severally followed by gentlemen on foot, and near to them, so much so that the workmen were obliged now and then to stop to clear the way for getting on. The makers brought with them some good practical working hands who were quite "at home" in the art of using these implements. The subsoiling was performed up and down the field, at different depths, varying from 12 to 18 inches below the surface, according as the draught chain was regulated. The Messrs. Ransome's also brought into competition with other makers, their four horse thrashing machine; and with this they thrashed out sixty-one bushels and three quarters of a peck of wheat, in the most complete manner, within one hour. Neither their two horse machine, or any other two horse machine was tried, nor were any of the hand thrashing machines tried against time, except one made by the before-mentioned gentlemen; this was worked by six men, who thrashed five bushels of wheat in 15 minutes. Several chaff engines were also tried of Messrs. Ransome's make, and quite astonished the observers, from the admirable manner with which they performed their work, and the good style of workmanship, particularly one on a large scale worked by two horses, for which their partner, Charles May, has just obtained a patent.

As soon as the prizes to the ploughmen were distributed, the company returned to Cambridge, where, at three o'clock p. m. the prize essays were read to a numerous assembly in the Law Schools, under the Public Library. The following are the titles of the essays:—

On the Storing of Turnips, by Mr. W. E. Geach, of Gywardreath, Lostwithiel, Cornwall, for which a premium of ten sovereigns had been awarded.

On the Admixture of Soils, by Mr. W. Linton, of Sheriff Hutton, near York, for which 20 sovereigns had been awarded.

On Early Spring Feed, by Mr. M. M. Milburn, of Thorpfield, near Thirsk, Yorkshire, for which 20 sovereigns had been awarded.

On Plantations, by Mr. Cuthbert W. Johnson, of Gray's Inn, which had obtained the gold medal.

On Gypsum as a Manure, by the same, for which a prize of ten sovereigns had been given.

Soon after five o'clock upwards of 400 noblemen and gentlemen sat down to a dinner provided in the magnificent dining hall of Trinity College, which had been kindly offered to the Council of the Royal Agricultural Society by the Masters and Fellows of Trinity.

There were eight tables, at which covers were laid

for 420. The dinner was served by the cooks of Trinity College, who provided one of the most sumptuous entertainments we ever partook of on a public occasion.

The tables were profusely ornamented with emblematical devices. On some of the tables richly gilt vases containing agricultural produce and beautifully executed models of animals; a bronzed statue of Edward III., one of the founders of the college, the pedestal of which was surrounded with martial emblems; a plaster model of the conduit in the great court of the college, and a statue of Henry VIII. (also a founder of the college), with figures of Piety and Learning seated at the base of the pedestal. These were executed by Mr Rennie of London.

Soon after five o'clock the Duke of Richmond entered the hall accompanied by Earl Spencer, the Marquis of Northampton, and the Duke of Rutland. Shortly afterwards the Vice-Chancellor entered, accompanied by Sir Robert Peel and Sir James Graham.

His Grace the Duke of Richmond presided, sitting at the centre of table A. 1. Earl Spencer acted as Vice-President, and sat at the extremity of table D.

Amongst the company we observed the following:
Dukes.—Richmond, Bedford, Rutland, St. Alban's, Buckingham.

Marquises.—Northampton, Salisbury, and Downshire.

Earls.—Spencer, Lucan, Chichester, Ilchester, Hardwick, Sandwich, Delaware, Stradbroke, Falmouth, Lincoln.

Viscounts.—Bridport, Sidney, and Neville.

Barons.—Lyttleton, Montegle, Hatherton, Wodehouse, and Braybrooke.

Lords.—C. Manners Crofton, Western, Braybrooke, Hatherton, Ashburton, Sondes, Dacre, Littleton, Lynedoch, Wodehouse.

Baronets.—Robert Peel, James Graham, Alexander Grant, Geo. Seymour, Thomas Gooch, Charles Morgan, Charles Burrell, T. Dyke Acland.

A Deputation from the Highland Society of Scotland, headed by Mr. P. Stewart, of Banffshire.

Ambassadors.—Hon. Andrew Stevenson, American ambassador to the Court of St. James's, the Hon. Virgil Maxie, ambassador to the Court of Brussels.

The celebrated French agriculturist, Count De Gourcy, and M. de Hamel, Councillor of State to the Emperor of Russia.

Hon. and Rev..—G. Neville Grenville, and R. Clive.

Sirs.—John Palmer, Robert Price, C. Brook Vere, John Johnstone, C. M. Clarke, Charles Lemon, H. Hoskins, C. Morgan, and W. Folkes.

Colonels.—Rushbrooke, Le Couteur, Pemberton.

The Very Rev. the Dean of Ely, the Vice-Chancellor.

Rev. Dr. French.

Professors.—Clarke, Whewell, Buckland, D.D., Cumming, Henslow, F. Worsley (Master of Downing).

Reverends.—Algernon Payton, W. Carus, Gurdon, Cheret, E. R. Benyon, D. Gwilt, J. Brown (Vice-Master of Trinity), T. Curtis, P. Gurdon, E. Fisher, — Rham, Bennett, J. Barker, C. Penrice, Leyson, and Penoyres.

Messrs..—J. W. Childers, M.P., R. J. Eaton, M.P., R. J. Townley, M.P., G. Pryme, M.P., E. Ashford Sanford, M.P., T. Hurst, M.P., W. Bagge, M.P., Abel Smith, M.P., J. Bennett, M.P., Bacon, Babington, P. Beales, G. Beauchamp, Barnett, Bavery, S. Bradfield, W. Bryant, Ratten, J. R. Barker, W. Booke, Bushfield, W. H. Cheere, B. Coldicott, J. Coates, Rakes Currie, Driver, J. J. Dobede, Eaton, Feere, J. Fryer, G. Fisher, T. A. Fisher, R.

Foster, jun. (mayor of Cambridge), E. Foster, J. N. Foster, J. E. Fordham, J. Poljambe, J. Grain, P. Grain, — Gurdon, Steed Girdleston, W. G. Hayter, M.P., H. Headly, G. H. Harris, Hillyard, W. P. Isaacson, G. Jenyns, W. Layton, G. Legard, Henry Long, Walter Long, T. Mortlock (High Sheriff of Cambridgeshire and Huntingdonshire), Francis Pym, Paris, P. Pusey, M.P., T. Page, C. Pemberton, G. Penrice, J. B. Rooper, W. Shaw, Jos. Tharpe, C. Towers, Sydney Tharpe, H. Thompson, H. S. Waddington, Tycho Wing, James Witt, and — Yorke, &c., &c.

The DUKE OF RICHMOND rose and said—My Lord Spencer, my Lords, and Gentlemen, I wish to propose the health of "The Queen," and may she long live happy and prosperous amongst us. (*Three times three.*)

The Duke of RICHMOND—I now rise to propose the health of one who has but lately come to reside amongst us, and who, during the short time he has yet spent in the country, has proved that he has the real welfare and prosperity of the people of England at heart—that this is in fact the country of his adoption, though not of his birth; and who the longer time he spent with us would (the noble President was sure) give the people of England continued occasion to manifest their gratitude for the devotion he showed their interests. He would give "Prince Albert," with three times three.

The Duke of RICHMOND then rose, and proceeded to say that he was about to propose a health, to which the hearts of all would respond with the deepest feelings of respect. He had but to mention the widowed Queen of our late revered Sovereign, with whose name he would join the surviving sons and daughters of that monarch (George III.) who in a peculiar manner had distinguished himself as the friend of agriculture, having no better pleasure than in going over his farm and personally inspecting the various processes which each returning season called into action, and in ministering with the hand of beneficence and power to the personal wants, and sympathising with the personal feelings of his dependents. He (the noble President) knew he could propose no health which would be drank with greater enthusiasm, by an assembly of farmers, than this. It was almost a personal appeal to the hearts of those present as the farmers of England, to call upon them to rise and drink with three times three the toast he had proposed. (*The toast was drank with immense acclamation.*)

The Duke of RICHMOND, on again rising, said that a want of gratitude, he was proud to say, had never been numbered among the faults of the farmers of England. The Society had incurred a deep debt of gratitude to the Master and Fellows of Trinity college, who had that day received them. Their lives were devoted to the education of the youths of the country. It was with pride that he could say that one of the greatest objects of the Society was identified with him—at least they wished to educate themselves. Nothing could tend more to the interests of the society than that system of a reciprocity of knowledge which such meetings as the present could not fail to induce. His (the Duke of Richmond's) early habits had not trained him to the practice of making long speeches, and for the present occasion the shortest he could utter would be surely sufficient to make the toast he proposed acceptable. He wished that it had been his lot to have been a member of such a society eight or ten years since, when he would have been better able to perform the arduous duties which were imposed upon him; and with the knowledge and information

he should then have had at command, he would have been more able to have done justice to his tenantry in introducing among them a better system of cultivation. For himself, however, it was too late to regret. There were present many who might take advantage of the benefits which this society must disseminate; and there were also many who, like himself, had children who would not be left to plead the excuse of ignorance to future generations. But the society, during the short time it had already been established, had done much. They were not to expect to reap their harvest before their seed was sown. They had done much, because their very organization had implanted in the minds of all, that indestructible tendency to improvement—that excitation to increased knowledge, which must progress, and could not retrograde. For their present accommodation, he would repeat that they owed a debt of gratitude to the Master and Fellows of the society within whose walls they were assembled; and to procure the warm acknowledgment of that feeling, he (the noble President) felt that he had only to mention their names to call forth the willing tribute which all were ready to pay. (The noble Duke concluded by proposing the health of the Master and Fellows of Trinity College with three times three, which was received with a loud burst of applause.)

The VICE-MASTER of Trinity College (the Rev. John Brown), said the unanimous kindness with which the toast of the noble President had been received, rendered him diffident when he rose in the name of the College to return his heartfelt thanks for their good wishes. That College might congratulate itself upon receiving into its walls a meeting convened to promote the best interests of the community. In such a meeting as the present there must always be something of enthusiasm, let it be assembled on any subject whatever; but the objects of the present were of a character especially calculated to draw out the best feelings in its favour. This society enlisted the aid of science to carry on the important pursuits it was designed to protect; and he trusted this meeting might originate the study of agriculture in the University, voluntarily added to the studies of those who came there to prepare themselves for the different avocations of life. (*Loud and enthusiastic cheers.*) He did not however wish it to be supposed that he thought agriculture would be left behind, when science was making such rapid progresses in every other department. In what related to the physiology of animals and the nature of soils, the labours of literary and scientific men would of necessity be productive of immense advantage to the practical farmer, but these labours must be disseminated in a simple form through the many districts of the land; and he was sure that not one of those men connected with the University of which he was a member, who had rendered their names famous for their scientific acquirements, but would feel proud that the studies of their retirement could be rendered subservient to the vital interests of so great a part of the community. (*Hear, hear.*) If such a professorship as that to which he had alluded should be established in this University, the results, he was sure, would be of such a character as would give the whole kingdom cause to be thankful for the institution of the society which had originated it. The pursuits of a University could not be alien from an institution designed to promote the increase of the prosperity, wealth, and comfort of the whole nation. The meeting of that day presented a striking contrast to those times mentioned by Columella (a Latin

author), when agriculture had neither teachers nor learners; it remained in a state of neglect and decay, which was permitted by Providence to be one of the principal causes of the ruin which shortly overtook that nation. Their fate was a warning to us how we trusted the staff of life out of our own hands. He would conclude by again expressing the deep sense of gratitude which he felt for the honour which had been conferred upon the college, by the manner in which the noble President had proposed, and the meeting received, the testimony the slight degree in which they had been enabled to be useful to the society.

The Marquis of NORTHAMPTON rose, and said that the toast which the noble President had proposed he had heard with the greatest satisfaction. The recollection of the benefits which he had in former days received from that College gave him still greater pleasure. The objects of this Society were of the utmost importance, not only to those immediately concerned, but to all who felt an interest in the welfare of their country. He was glad of the opportunity, as one of the members of that Society, of testifying the respect which he felt for the noble duke who presided on the present occasion. The President had truly said that in the virtue of gratitude the farmers of England had never yet been found deficient; but, should they not receive with the utmost demonstrations of sincere thankfulness the mention of the services of that noble personage, it might indeed be supposed they had ceased to be influenced by that feeling. The noble duke seemed placed by Providence in a situation peculiarly adapted for the position he had been selected to occupy, having estates both in England and the north of Scotland, having means at his command for trying the relative merits of the respective systems of agriculture pursued in both countries, and being thus qualified to judge of their comparative merits. It was quite true that agriculture as a scientific pursuit was still in its infancy, because it was only recently that meetings like the present had taken place. Agriculture, indeed, did not only embody one science, but he might say that it was a pursuit which to carry to perfection ought to combine a knowledge of all the sciences. It was important that the chemist should throw the light of his researches upon it—that the botanist should add his knowledge of the growth of the various plants which nature had given to the care of man—and, in a word, that philosophy of all descriptions should be united to enlarge the sphere of the labours of the farmer. Agriculture was indeed yet in infancy, but it required only that those whose lives were devoted to literature and study should combine to teach the farmer, and it would soon reach, if not to maturity, to a degree of perfection which it would be difficult to describe. He would not detain them longer than again to propose the name of his noble friend, whose views he was sure were such as to render the toast well calculated to call for the sincerest feelings of gratitude and pleasure. (*The toast was drunk with three times three and one cheer more, amidst the loudest acclamations.*)

The Duke of RICHMOND, in rising to return thanks, said that his noble friend had proposed his health in terms much too flattering, when applied to any merit which he could presume to take to himself. He had not, however, said too much when he declared that he had endeavoured to promote the interests of the agriculturists. He had done so, not because his own interests were involved in them, but because he felt that in the welfare of agriculture consisted the prosperity and welfare of the country.

It was, indeed, of great importance to him, but of still greater to his country, that agriculture should flourish, for when it flourished neither commerce nor manufactures stood still. He had promoted agriculture, not because he found himself a land-owner, but because he also was proud to say he was a farmer. He could not venture to call himself a practical one, but he knew that if the landowners did their duty to their tenants, they would perform their duty to their labourers. Thus were they bound together by one link in the chain of society. It was a union of classes which must ever be productive of the best interests of mankind; by such a union the whole country maintained its prosperity. United, they were the instruments of great good, they made themselves respected by other nations, and preserved themselves from foreign foes. The compliment which had been paid him he would not take to himself, but to his office: it was one he should ever feel proud to fill. The honour had been conferred upon him solely because he was placed at the head of the agricultural interest, to which office he had been appointed not as a matter of form, but selected owing to his good fortune in having (in conjunction with Lord Spencer) first proposed the organization of this Society. It was formed owing to a conversation which he had with that noble on the occasion of a Smithfield Cattle Show, when his lordship had suggested the utility which the foundation of such a society could not fail to produce. His noble friend had been in his county; he had seen the good effect which had resulted from the Highland Society. He could not gratify the meeting by stating which of the two obtained the pre-eminence; nor would he draw any invidious comparisons, but content himself by saying that he was sure that the members of this society would be received by their brethren in Scotland with the same feelings of hospitality as they had exercised towards himself. He would return, however, to the establishment of this Society. From the suggestions which had been thrown out between himself and his noble friend upon the occasion to which he had alluded, it had been established, and its establishment had been followed by the most triumphant success. At their first meeting last year at Oxford they had numbered 1200 members, but he now rejoiced to state that their numbers amounted to 3500. It had been repeatedly said that the Society could not continue to exist, unless supported by practical farmers;—they had met with that support. He would however take that opportunity of stating, that one important ingredient in their success consisted in farmers taking the trouble of communicating continually to the Council the results of the different experiments which they were in the habit of making. They were not a theoretical society, but their object was to reduce theory to practice. He would not be thought to depreciate the value of experiments, but would recommend the adoption of such improvements the success of which had been proved by the result. He begged to thank them again for the honour they had done him, and to express the gratification he felt at the successful prospects of the Society. (*The noble duke resumed his seat amidst great cheering.*)

His GRACE again rose and said that the lists had just been put into his hands, containing the award of the judges. It might be satisfactory to explain the rule which the judges observed; and especially so as some gentlemen for whom he (the Duke) had a high respect did not, he believed, think it in all respects right and proper. When Lord Spencer acted, on a former occasion, as one of the judges, numbers were made use of that, when they went up to the pen, they should not

be aware of the name of the owner of the animals therein. But they since found that they should place full confidence in the judges. They had this difficulty, amongst others, in the old system to encounter, that the shepherd who was with his children (*laughter*), watching them with a jealous care, was invariably known to some one or other of the judges. This did not exist in the new system, which excluded every person connected with the animals. In all such matters absolute perfection could not be accomplished or hoped for. In this world it was in carrying out any undertaking but a choice of difficulties, and his experience through a long life had always found it so. The fullest confidence of the society in the judges was, therefore, deemed necessary to the best adjudication, and they were selected in a manner calculated to inspire confidence.

Earl SPENCER here said that the judges themselves did not at that moment know the names of the successful candidates.

The Duke of RICHMOND then read the award of the judges as follows:—

FIRST CLASS.—*For Short Horned Cattle.*

Best Bull—Mr. W. Paul, of Pentney, Norfolk. . . 30 sovs.
 Best Yearling Bull—Mr. R. N. Jaques, of Richmond, Yorkshire 15 sovs.
 Best Cow, in milk—Mr. Thos. Bates. 15 sovs.
 Best In-Calf Heifer—Right Hon. Charles Arbuthnot 15 sovs.
 Best Yearling Heifer—Mr. R. N. Jaques, of Richmond, Yorkshire 10 sovs.
 Best Bull Calf—Mr. Thomas Bates 10 sovs.

SECOND CLASS.—*Hampshire Cattle.*

Best Bull—The Duke of Bedford 30 sovs.
 Best Cow, in milk—Sir Hungerford Hoskyns, Bart. 15 sovs.
 Best In-Calf Heifer—Sir Hungerford Hoskyns, Bart. 15 sovs.
 Best Yearling Heifer—Mr. Francis Hewer, of Hereford 15 sovs.

THIRD CLASS. *Devon Cattle.*

BEST BULL CALF.

Best Bull—Mr. Porter, of Hembury Fort . . . 30 sovs.
 Yearling Bull—The Duke of Norfolk 15 sovs.
 Cow, in milk—Mr. T. Umbers, of Wappenburg, Warwickshire 15 sovs.
 In-Calf Heifer—Mr. Turner, of Barton, near Exeter 15 sovs.
 Yearling Heifer—Mr. Turner 10 sovs.
 Bull Calf—Mr. T. Stephens, of White Lackington, Staffordshire 10 sovs.

FOURTH CLASS.—*For Cattle not qualified for either of the above Classes.*

Best Bull—Mr. Putland, of West Firs, Sussex, for his Sussex Bull 30 sovs.
 Best Yearling Bull—Sir Edward Kerrison, Bart., of Oakley Park, Suffolk, for his Yearling Suffolk Bull 15 sovs.
 Cow, in milk—Mr. Putland, for his Sussex Cow . . . 15 sovs.
 In-Calf Heifer—Mr. Putland, for his Sussex Heifer 15 sovs.
 Yearling Heifer—Mr. Putland, for his Sussex Yearling Heifer 10 sovs.
 Bull Calf—Mr. Putland, for his Sussex Bull Calf 10 sovs.

FIFTH CLASS.—*Horses.*

Judges:—Mr. J. Clarke, Barnaby Moor; Mr. C. Bowman, Greatford.

The best Cart Stallion, Mr. John Bell, of Wellen-le-Wold, Lincolnshire, for his 12 years old cart stallion, bred by Mr. J. Adams, of Landbeach, Cambridgeshire 30 sovs.
 The best Cart Mare and Foal, to Mr. T. N. Catlin, of Chillesford, Suffolk, for his cart mare and foal, bred by Mr. Cooper, of Friston, Suffolk 15 sovs.
 The best Stallion for breeding hunters, carriage.

horses, or roadsters, which shall have served mares during the season of 1840, at a price not exceeding 3*l.* each, to Mr. John Reynolds, of Wisbeach, Cambridgeshire, for his eight-year-old stallion, bred by Mr. J. O. Taylor, of Fleixton 30 sovs.

SIXTH CLASS.—For Leicester Sheep.

Shearling Ram—Mr. Samuel Bennett, the First Prize 30 sovs.
Second Prize—Mr. Samuel Bennett 10 sovs.
All-age Ram—Mr. Pawlett, of Tinwell, Rutland 30 sovs.
Five Ewes and Lambs—Mr. Inskip, of Marston, Beds 10 sovs.
Shearling Ewes—Mr. Wm. Pawlett, of Barnack, Northamptonshire, for his 5 Shearling Ewes 10 sovs.

SEVENTH CLASS.—Southdown and Short-woolled Sheep.

Shearling Ram—First Prize, the Duke of Richmond, for his Southdown Shearling Ram. 30 sovs.
Second Prize—Mr. Crisp, of Gedgrave, Suffolk, for his Southdown Shearling Ram 10 sovs.
All-aged Ram—Mr. Crisp, for his three-year-old Southdown Ram 30 sovs.
Five Ewes with their Lambs—Mr. Jonas Webb, of Babraham, for his five Southdown Ewes and Lambs 10 sovs.
Five Shearling Ewes—Mr. Jonas Webb, for his five Southdown Shearling Ewes 10 sovs.

EIGHTH CLASS.—Long-woolled Sheep.

Shearling Ram—Mr. C. Large, of Broadwell, Oxfordshire, for his long-woolled Shearling Ram 30 sovs.
Second Prize—Mr. John Haradine, of Needingworth, Hunts, for his Long-woolled Shearling Ram 10 sovs.
All-age Rams—Mr. Charles Large, of Broadwell, Oxon, for his New Oxfordshire Long-woolled Ram 30 sovs.
Five Ewes and Lambs—Rev. James Linton, of Hemingford Grey, for his five Lincoln and Leicester Ewes and Lambs 10 sovs.
Five Shearling Ewes—Mr. E. Smith, of Charlbury, Oxon, for his Improved Oxfordshire Shearling Ewes 10 sovs.

CLASS NINE.—For Pigs.

Best Boar—Mr. Barnard, M.P., of Gosfield Hall, Essex, for his one year and four months old Boar.—This Boar was from the stock of Mr. W. T. Hobbs, who won the next prize... 10 sovs.
Best Sow—Mr. W. F. Hobbs, of Marks Hall, Essex, for his three-year-old Sow 5 sovs.
Three Best Pigs—Mr. G. Kirkby, of Eppinbury, Essex, for his thirty-six-weeks old Pigs 10 sovs.

The Noble PRESIDENT stated, that the Prizes for Horses would not be declared until the next day.

His GRACE then said, before he proceeded farther he should propose "the health of Mr. Putland," who had been so successful a candidate, and whom he was proud to call a Sussex man.

The Noble VICE-PRESIDENT proposed "The healths of the successful candidates."

The Duke of RICHMOND said he felt proud of being enabled to carry back the prize for the best Southdown ram into Sussex. As president he had felt it his duty to send his best stock; he had also forwarded some ewes, which were not successful. He, however, felt additional satisfaction in receiving his prize, because if they read the journal of the society's proceedings it would be found that his noble friend (Lord Spencer) considered the male animal by far the most important. (*Hear, and laughter.*) He suspected the county of Sussex would not long be able to retain the first prize, unless the breeders continued very active, for this year there had been no less than fifty-four other competitors. In justice to Lord Spencer, he thought it right to state that his noble friend, as all would readily believe, could have sent several animals for the different classes from

his splendid collection of stock, but he felt that he could be of more real service to the society by acting as a steward of the cattle-yard, and his high sense of honour, therefore, dictated to him that as such he could not be an exhibitor. (*Cheers.*) He should soon have to propose the health of his noble friend, and he was sure that in every assemblage of farmers his name would be received with three British cheers. (*Applause.*)

The Duke of RICHMOND then proposed "The health of the successful exhibitors of wheat and pigs."

Colonel LE COUTEUR said his Grace the Chairman had turned his sword into a ploughshare, and he (Colonel Le Couteur) had humbly followed his example. He was one of those who thought that a retired soldier need not be entirely put upon the shelf, but might become useful in other spheres. As to the growth of wheat, he might observe that he had long been of opinion that a pure sample would be the one most likely to ensure a good crop; he had been told that it would be impossible to obtain in England a seed and crop equal to the Polish mixed corn, but as soon as he began to plant he was convinced of the error. He was satisfied that the farmers of this country could grow as pure and excellent corn as that imported, the principal requisite being a proper selection for the soil planted. He was much surprised at having obtained the prize; his sample was grown from a single grain, and he had now been seven years rearing it; consequently much patience and care had been required; and that circumstance suggested to him the justice and propriety of the society having an experimental farm. With individuals at least three years was necessary to complete any experiments, but with a farm the same results might be obtained in one year. If not out of order, he would suggest that a fund be established for that purpose by a subscription of 1*l.* a year.

The Duke of RICHMOND said it was impossible for any one present not to be impressed with what had fallen from the gentleman who had just addressed them. With respect to his hint respecting the experimental farm, he thought that this great country ought to have one, but the society was an infant one, and it could not attempt too many things at once. There were many, and amongst the number his Grace himself, who would be happy, when the period arrived for making the experiment, to subscribe largely towards it. But their object would be to enable the farmers of England to send their children to it for their education, and in this he would include moral and religious instruction. He hoped that next year this important subject would be discussed at the meeting of the society, which would be held in a great commercial place, where, he hoped, that the manufacturers of the country would receive them in the same spirit of friendship as they (the farmers) would receive them were they to come amongst them. (*Cheers.*) Those who wished to stir up enmity and jealousy between both these great classes were not the friends of the country. (*Loud cheers.*) The noble President then proposed "The health of Earl Spencer," which was received with tremendous cheering.

Earl SPENCER said he had been called upon to give his opinion respecting the growth of wheat; that, however, was not exactly the portion of agricultural pursuit to which he most particularly directed his attention, because he had thought much more of the breeding and feeding of stock. He might, however, observe generally that science had not been applied to agriculture as it ought to have been. He would say let every farmer try experiments where he thought there was ground for any improvement, and he would be sure thereby to benefit his country and himself. (*Hear, hear.*) Great care should of course be taken in the selection of seed wheat, as some soils suited one description and some another. It was a common practice to take from a light land for sowing on a heavy soil, and the contrary. It would certainly be a fair experiment to try whether it would not be as well to take the seed from land similar to that upon which it was to be sown. If a mixed variety of seed was sown an indifferent crop must be the result, because one portion would do much better than the other. He would recommend the trial

of various experiments by sowing different samples on a variety of soils.

The Duke of Richmond then mentioned the name of Professor Henslow in terms of warm praise, as a gentleman capable of imparting most valuable information to the meeting; and his Grace expressed a hope that the learned professor would favour them with his opinion on the subject which they all had at heart.

Professor Henslow said he could not respond to the appeal which was made to him without great diffidence, nor could he venture to suggest to those who had practical knowledge on the subject anything respecting the growth of wheat—a subject on which he himself possessed no practical knowledge whatever. All that he knew respecting this plant related chiefly to those laws of vegetation by which the growth of every plant was regulated, and to enter into minute details respecting that complex problem would require him to trespass too long upon their time, and would possess too much the character of a lecture. Indeed, he could hardly hope to do justice to such a subject without detaining them in their seats for a week at least. But, having been called upon, he felt that he could not sit down without mentioning one piece of advice, which, if it were acted upon, would be of the greatest importance in furnishing scientific inquirers with a mass of material from which they might be enabled to draw accurate inferences, respecting those laws of vegetation of which at present so little was satisfactorily known. In the present state of science all England might be considered as one great experimental farm, and the daily operations of the agriculturists as so many experiments. If persons would only register the results they obtained in all cases, at the same time stating a variety of attendant circumstances bearing more or less directly on those results—such, for instance, as the state of the weather, of the wind, and numerous other minutiae which need not be dwelt upon—then indeed we might hope to be gradually enabled to understand more of those great laws of vegetation by which the growth of plants was regulated. He had passed many years of his life within the walls of this university in studying and lecturing upon this subject, so far as it was at present understood; and now that he was living in the country, he had commenced certain experiments, which he hoped, if he should live to see the result, might assist in furthering our knowledge of those laws; and nothing would give him greater pleasure than detailing such additional information if he ever obtained it; but he was afraid to trust himself on the present occasion with attempting any general exposition of what was hitherto known and recorded respecting the laws of vegetation, for the reason already stated.

The Duke of Richmond next introduced Professor Buckland, of Oxford, to the meeting, and reminded them of the rich treat which he afforded the society last year. He hoped that he would permit him in the name of the farmers of England to call on him on this occasion for some farther valuable information, and, if it related to the cultivation of wheat, he would say for himself and his brother agriculturists that they should feel the more indebted.

Dr. Buckland, whose appearance was hailed with loud cheering, said the kind manner in which his name had been received made him cease to regret the absence of his friend and colleague, Professor Sedgwick, who would have addressed them more eloquently than himself, and most satisfactorily proved that the farmers were all greatly indebted to the science of geology. (*Hear, hear.*) A large portion of the company might perhaps have seen in the passage to the committee-room at the University Arms, that day, a very large map decorated with various colours, which to some would no doubt appear unintelligible, though to a great number it was now no longer so. They were all of the greatest importance to the agriculturist, each stripe showing a different soil, and exhibiting the various strata of earthly matter which formed portions of this their native country. (*Hear.*) A suggestion had been made of having an experimental farm; he must say that he thought that would be of very little general utility. He would suggest that there should be at least twelve farms, not,

however, such as would consume the funds of the society, but to be established by noblemen and gentlemen, who could place them in the hands of able and practical men, by whom the most valuable information could be conveyed to geologists. He was of opinion that a committee should be appointed for the purpose of making selections and drawing up a general system of experiments, and that they should occasionally make reports of the result of experiments upon different soils—a plan from which the most valuable results might be anticipated, for no geologist ever walked over a farm without discovering different formations of earth, all of them probably being of much importance. The Learned Professor then briefly referred to the advantage of an admixture of different soils, such as chalk and clay with sand, by which many lands might be brought into excellent culture, and regretted that time would not allow him to refer to many other interesting topics. The various suggestions, however, which could be made would only be carried out through the aid of a committee, which he hoped to see very speedily formed. (*Cheers.*)

The Duke of Richmond proposed "The health of Mr. Maxie, the Minister of the United States to the Court of Belgium." It was the wish and endeavour of that gentleman, who then honoured them with his presence, to seek and obtain information on all subjects like that which called them together, the object of which was the prosperity of the human race. The country he represented in days gone by was a province of England; it was now an independent nation. They had been at war, and now they were in peaceful relation to each other, united by kindred sympathies and interests. (*Cheers.*) Peace was dear to the heart of the farmer; in promoting his interests he promoted the dearest interests of his country, and these he pursued without wishing for or requiring the inferiority or the ruin of others. His Grace expressed a hope that we should long live in peace and the cultivation of good will with a people who had sprung from Great Britain, and of whom she might be justly proud.

Mr. MAXIE was received with great cheering. He said he felt that it would be the highest presumption should he take to himself that honour which, in proposing his name to that assembly, he considered was meant for the country of which he was a native. Individually he felt the highest pleasure in being present at a meeting assembled for the furtherance of the noble objects which they had in view; and he also thought it no slight honour to be there, the representative of a country which was bound with them by the mutual wish to extend the interests of agriculture. His country deserved the esteem of the society, not merely because her institutions, language, laws, and customs were those of England, but more especially because they were the descendants—children of England, who had turned a savage and desolate wilderness into a civilized nation, and had vindicated their claim to be ranked among those benefactors to the human race of which England held the highest place. The objects of that society were to promote the greatest interests of the country. Agriculture was the greatest instrument for the diffusion of the blessings of civilization; and though England was the greatest nation on the earth for commerce and manufactures, her agriculture formed her greatest glory. (*Loud cheering.*) He might say that manufactures formed the Corinthian capital of the column of her glory, of which commerce was the shaft, but agriculture the solid base which supported the whole. How important a part of the population of this country the agriculturists formed might be ascertained from the fact that the returns of the income tax furnished; two-thirds of that tax were paid by them. Still nobler purposes were carried forward under its influence. Civilization was promoted, the welfare, both moral and physical, of the people enlarged, and that force of mind, without which all other advantages were nothing, increased. He would repeat how much he was indebted to those who had procured to him the pleasure of being present that day, and the high sense he entertained of the honour done him by the Noble Duke, to whom he begged leave personally to express his profound acknowledgements. He could only conclude with the hope that the two

countries so nearly connected in sympathy might ever continue in the exchange of a contest of which should do the other the greatest good, and again never recur to that where the only object was to do the other the greatest harm. Might peace and good-will reign between them, and might they be united in feeling, in happiness, and in glory. (*Loud cheers.*)

MR. WREB HALL returned thanks. Though second to no man in respect to the constituted authorities, he would never shrink from claiming the just and fair rights of his class. The English tenant who provided capital for the cultivation of the landowners' estates, had a right to stand on the footing of independence. In the same manner he was prepared to yield to the labourer, as the weaker party in his transactions with the farmer, his just rights. There were some of the statements of the learned Professors which he could not think calculated, at present, to yield the farmers that great practical good which they might seem, at first sight to offer. Had he heard the speech of Professor Buckland, at Oxford, he should have been tempted to object to some of his positions, particularly when he stated that fertile lands might almost be compounded by the mixture of soils, leaving out of consideration that grand component, manure. He had since corresponded with the Rev. Gentleman, and he was glad to find that Mr. Morton, who was carrying on experiments with manures, was of the same opinion with himself. He exhorted the farmers not to neglect the collection of the utmost quantity of manure, at the same time that they availed themselves of those solid improvements which science and practice might discover.

The Duke of RICHMOND rose to propose the last toast which he should call upon them to drink that evening, and in appropriate terms introduced the health of the "Tenantry of England," which was drunk with three times three.

The Duke of RICHMOND said he must call upon them to drink one other toast before they separated, and proposed "The health of the Vice-Chancellor."

The VICE-CHANCELLOR (the Rev. Dr. Tatham) returned thanks, and the meeting separated.

DINNER ON WEDNESDAY IN THE GREAT DINING HALL ERECTED IN DOWNING COLLEGE.

At four o'clock, the company had mostly arrived, and the hall presented a truly animated appearance, crowded in every part with eager and gratified guests. There were two thousand six hundred and fifty persons present. At a few minutes after four o'clock the Duke of Richmond took the chair, and was received with much applause, as were many of the noble and distinguished guests who accompanied him, especially the Duke of Buckingham, the Duke of Rutland, Sir Robert Peel, Sir James Graham, &c.

The noble Chairman was supported on the right by the Hon. and Rev. G. N. Grenville, Master of Magdalen College, the Duke of St. Albans, the Duke of Buckingham and Chandos, Sir J. Graham, Bart., M. P., the Marquis of Downshire, Professor Henslowe, &c. On the left of the noble chairman were the Duke of Rutland, Mr. Stevenson, the American Ambassador, Sir Robt. Peel, Bart., M. P., Professor Buckland, the Marquis of Northampton, the Rev. Dr. Worsley, Master of Downing, the Earl of Hardwicke, Lord Charles Manners, Visct. Bridport, Earl Bathurst, &c. Among the more distinguished guests on the platform were Lord Lytton, Lord Falmouth, Mr. Maxie, the American Ambassador at Brussels, the Earl of Lucan, J. Webb, Esq., the Marquis of Salisbury, the Hon.

Charles H. Manners Sutton, Earl Chichester, Thos. Page, Esq. of Ely, P. H. Frere, Esq., J. W. Childers, Esq., M. P., E. A. Sandford, Esq., M. P., Professor Whewell, Lord Dacre, Lord Montague, Dr. Prince, Master of Jesus College, Colonel Rushbrooke, M. P., Sir Alex. Grant, M. P., Richard Foster, Esq., jun., Mayor of Cambridge, &c., &c.

The dinner having been concluded,

Grace was sung by the choristers of the University and Ely, after which due justice having been done to the viands, "Non nobis Domine," was also performed by them.

The Duke of RICHMOND said he was about to propose to their notice the name of their illustrious patroness,—the Queen. (*Great Cheering.*) He well knew, the loyalty and devoted attachment of the farmers of England had been tried on many and various occasions. Their attachment to their country and their loyalty to their Sovereign, had been often proved at the expense of their blood. Any further appeal to them on the present occasion, would, he felt, be almost an insult. It was unnecessary to say more than to mention the name of Her to whom the hearts of the people of England were so strongly bound; might, under the blessings of Providence, her reign be long and happy, and might she long continue to enjoy that domestic felicity which was her present lot. He called on them to rise and drink health and happiness to their Queen. On his grace concluding the whole of the vast assembly rose up and with loud and enthusiastic cheering, drank the toast which had been proposed. After which "God save the Queen," was sung by the University choir, the whole party joining in the song.

The PRESIDENT again rose and said, he had no doubt of the reception that would be given to the next toast which he had the honour to propose—"The health of that young and illustrious Prince who had gained the affections of our beloved Queen." Since that prince had come amongst us, he had shown every wish to be of service to the country of his adoption (*loud and long-continued cheers marked the reception of the toast.*)

The noble PRESIDENT then proposed—"The health of the Queen Dowager and the rest of the Royal Family" (*continued cheering.*)

The noble PRESIDENT then called on Sir Robert Peel to propose the next toast, "Success to the English Agricultural Society."

The RIGHT HONOURABLE BARONET rose, in the midst of a tumult of applause, which continued for some minutes, on the subsiding of which he said, that it would be affectation in him to mistake or misunderstand those demonstrations of esteem and personal good-will, which induced, or rather compelled, him to pause a moment in the execution of that duty which had been delegated to him by their noble president. When he surveyed this imposing, he had almost said this awful, scene—when he recollected the purpose for which they were met—when he thought of the wide area from which they were assembled, and the great interests which they represented—when he remembered the class to which, mainly, they belonged, and what had been the conduct, and still was the character, of that class—when he called to mind their moderation in prosperity, their patience and fortitude in adversity, their cheerful obedience to, or he should rather say, their zealous co-operation with, the laws, and their tried fidelity and loyalty to their Sovereign—when he thought upon all these things, however imperfect the acknowledg-

ment might be, they would believe that he did deeply, and would permanently, feel the distinction which the good opinion of such a body conferred upon a public man. It had been assigned to him, by those who had the conduct of the arrangements of the meeting, to propose the toast which had the most special reference to the occasion of that festival, and which, if he mistook not, would be in perfect unison with the feelings of that great assembly. That toast would convey an earnest wish that the future progress of this society might be as satisfactory as the past—that every succeeding meeting might exhibit proofs of improvement caused by its instrumentality—might show an increase in their numbers, and, by that increase the possession of extended means of public usefulness (*cheers*). It was, perhaps, to be regretted that this toast had not been assigned to some one more practically versed in agriculture than he could pretend to be, but there might be something to make up for this in the deep interest he felt in the prosperity of the land, and the fact that he had been present at the birth of the society—that he had most cheerfully and zealously co-operated with his noble friend, Earl Spencer, in laying the foundations of this important association. He well remembered when they met with members in numbers few, and with some forebodings of failure; but when he (Sir Robert Peel) obtained as a fundamental principle of the institution, that all party feelings should be excluded, he felt confident that they must, in the end, be successful (*long-continued cheering*); and he thought he could refer to the proceedings of the day as proofs that his predictions had not been falsified. He should now make use of his public character, only to exhort those whom he addressed, to that which was the primary principle of the society, and essential to its success, and to entreat them that they would, by the influence of that public opinion they were so well qualified to guide, induce others who might have been engaged in party warfare, to deposit at the threshold of this temple of peace, those weapons which might be fitly used in political conflicts, and which he himself had very recently wielded (*tremendous applause*). It would be superfluous in him to dilate on the benefits which this society must confer upon agriculture. To do this, did not require any great amount of practical knowledge. Could any one have attended the show held not very far from these walls, without feeling convinced that had the whole body of farmers in England seen the exhibition of implements and stock there made, they would have deposited at that door a thousand hitherto cherished prejudices? They would have felt convinced of the benefits which science confers on agriculture, and have laid aside the not unnatural opinion that the instruments and means which their forefathers had used were the best which they could at this time employ (*cheers*). He would leave to others the task of dilating on these and similar benefits of the society. He, as a public man, was fain to contemplate other results springing from the exertions of such a body. He thought there would be, as in almost all cases there was, a useful combination of physical and moral good, not merely leading to the fulfilment of the divine command, "increase and multiply." He thought they were at once scattering plenty over a smiling land, and extending the influence of kindness and kindly feeling around—that they were, so to speak, ploughing up the sub-soil of feelings and affections (*applause*), exposing

what would otherwise have remained barren and inert to the influence of social converse and social intercourse; that, in a word, they were sowing upon earth the seeds of "peace and good will towards men" (*cheers*). He believed, moreover, that this institution had a tendency to encourage the landowner to apply himself to a noble and dignified relaxation, full of interest in itself, and fraught with advantage to his country, to teach him the full value of scientific acquirements, and the truth that knowledge was not only power, but wealth also—that in knowledge resided an influence equal to that of riches, of birth, or of station (*cheers*). Further, he believed, it had tendency to keep the landed proprietor at home: to give him an interest in country pursuits, which would induce him to remain the centre and support of those amongst whom he moved, and who depended on him—that it would enable him to resist the temptation to leave his home which the facilities of locomotion furnished. It would also, he thought, strengthen and confirm the connection which united the landed proprietor with the yeomanry, and both with the labouring classes (*loud applause*). It would give them a common topic of conversation; it would serve to remind them that they were all members of the same dignified corporation; to teach them that the hand which labours belongs to the same body as the head which conceives, and the mind which creates; that the three classes were bound by the golden link of common interest and common purpose (*hear hear*). They must excuse him if he expressed his cordial gratification at bearing of the place which had been selected for the meeting of the ensuing year. They would indulge him if, as a native of Lancashire, he felt proud to hear that the great outlet for the manufactures of England had been chosen for the meeting of the Agricultural Society. It was not unnatural that he, the son of manufactures and commerce, who felt the deepest obligation to these for worldly prosperity, and owed to them all the interest he had in the land, should rejoice in the prospect of seeing the commercial interests brought face to face with the agricultural. He was convinced that such a meeting would confirm the natural and almost unanimous opinion which prevailed, that a relation subsisted between them, so close, that they could not be disunited; that it was impossible that manufactures should flourish without shedding a kindly influence on agriculture; or on the other hand, that agriculture could decline, without involving manufactures in its decay (*applause*). There was yet another reason for which he rejoiced that the standard should be planted on the coast of England, on the point which admitted the greatest facilities for intercourse with Ireland and Scotland. From this fact also, he looked for great social results. By this choice they invited Scotland to witness how they had followed her example, and called upon Ireland to follow theirs; and, tempted by no narrow or exclusive spirit, asked Ireland and Scotland to communicate those improvements they might make, and participate in those of this country. They would thus encourage them to enter into that generous and unselfish competition which enabled even the disappointed competitor to retire from the scene, not dissatisfied, and thinking more of the general improvement than of his own individual interest. Such union could not but confirm the friendly feelings and relations of the two countries. The toast which it was his duty to propose was "Success to the English Agricultural Society." It be-

came necessary to call it English on account of the locality to which it was confined, but it had in view to render common benefits to the empire, and not merely to England. With these feelings, reflecting cheerfully on the past, and with cordial anticipations for the future, he would call upon the meeting to drink, with as much enthusiasm as was consistent with the safety of the walls and roofs of the building, the toast which he had the honour to propose—"Success to the English Agricultural Society."

The NOBLE PRESIDENT again rose and said that he had the honour to call on his Grace the Duke of Buckingham to propose the next toast (*loud cheers*.)

The Duke of BUCKINGHAM said that he felt deeply the honour conferred on him. The truly gratifying reception which his name had just met should never be effaced from his memory, and he should on all occasions be ready to prove his high sense of their kindness (*cheers*). The union of commerce, manufactures, and agriculture, was amongst the dearest wishes of his heart. He had always advocated this principle, as he was of opinion that the prosperity of the one depended on the prosperity of the other (*cheers*). He would therefore, without trespassing on the time of the meeting, call upon all present to drink with three times three the toast which he had been called on to propose, namely, "Commerce, manufactures, and agriculture." With the firm union of the three the country must prosper, under the blessings of Divine Providence, in spite of every effort against her (*loud cheers*).

The Duke of RICHMOND then requested the Marquis of Northampton to propose the next toast, and recommended his Lordship to go to the front table.

The Marquis of NORTHAMPTON, in rising to the call which had been just made upon him by his noble friend, regretted that the toast he had to propose had not fallen into worthier hands. It required, however, but to mention the name of the University of Cambridge to have its merits appreciated. Within its walls they would be guilty of that ingratitude which the noble president had said last evening dwelt not in the bosom of English farmers, were they not to express their hearty acknowledgments to the University for their liberality on this great and interesting occasion (*cheers*). The name of the distinguished nobleman at the head of this learned body he was quite sure would be received with pleasure, and hailed with gratitude, by every honest and true-hearted Englishman present. That virtuous man had already laid down several hundred thousand pounds for the necessities of his country (*loud cheers*). Commerce was a good thing—manufactures were a good thing—Agriculture was a good thing; but public virtue was better than all (*great cheering*). Commerce, manufactures, and agriculture united, tend to prosperity and strength; but we could not expect them to be united, and the interests of the country to succeed, without the blessings of Divine Providence. In such distinguished and honourable men, as Lord Camden, this principle was personified, and they held out a bright example which it would be well for the community if it were oftener followed (*cheers*). Lord Camden had served his country long, and long might he live to prove his love of that country, and to deserve her gratitude (*long continued cheers*).

The noble PRESIDENT said, that in the absence of the Vice-Chancellor who had written to him

apologising for his unavoidable absence, the Master of Magdalene would respond to the toast.

The Honourable and Reverend NEVILLE GRENVILLE, master of Magdalene, briefly returned thanks. He could take it upon himself to say, on behalf of the authorities and heads of the body to which he had the honour to belong, that it was their wish, and should always be their earnest endeavour, to promote the interests of their tenantry; and to carry out those great objects which the Society had in view.

The noble PRESIDENT, in proposing the next toast, which was the health of a distinguished individual present, the Honourable A. Stevenson, minister of the United States, and an honorary member of the society, said that he well knew the farmers of England; and they would all warrant him in saying that they wished, one and all, for peace and tranquillity (*cheers*). When war and danger desolated the fairest portion of the world, and when their horrors seemed to threaten our homes from abroad, the farmers and labourers of England were found ready to risk their lives in defence of their country. They were ready again to make the same sacrifice, should the occasion arrive to call for it; but peace at home and abroad was what they wished for; they did not long to see other nations laid waste, that they might be prosperous; it was not their interest or desire that other people's farms should be desolated, their barns destroyed, and their towns and villages plundered (*cheers*). Those who wished for the blessings of peace they met half way, and in this spirit did they meet the good wishes of the American people, whose representative at the court of our Sovereign did them the honour of being present on this occasion (*cheers*). The honourable and distinguished individual to whom he alluded was one of that great nation which had sprung from ourselves; and he (the Duke of Richmond), in the name of the farmers of England, wished it every prosperity, and that it might long continue in peace with this country, cultivating with her those arts and sciences which tended to better the condition of the human race and make it more happy (*loud cheers*). With respect to the honourable gentleman himself (Mr. Stevenson), he had great pleasure in testifying to his character in public and private life, and he was moreover a tried friend of agriculture. He felt interested in the improvement of agricultural science in England, as they should that the same good should extend to America; for the object was not only the agriculture of the land we live in, but the agriculture of the world (*loud cheers*).

MR. STEVENSON, the American minister, rose to return thanks, and was received with loud cheering. He said, in the course of a public life, not very short, he had never been called upon to address so numerous and remarkable an assemblage, and it would be an unworthy affectation if he did not say that he felt his situation novel and embarrassing. He feared that he could not do justice to his feelings and the occasion. The kind and hospitable reception which he had met with, and the gratifying manner in which their noble president had associated his name with that of the two countries, demanded his grateful acknowledgements. He received it with feelings of just pride and sensibility, enhanced as it was by the motives which he believed had prompted it, and the flattering manner in which it had been received by such a distinguished assembly. Deeply sensible, however, as he was of such high honour,

he should but inadequately convey what he felt if he confined himself to the expression of his personal feelings. In relation to himself individually, it was a matter comparatively of little importance; but in another sense, and looking at such an assembly, representing as it did not only the great agricultural interest of England, but of the united kingdom, such kind and liberal sentiments as those which had been expressed were calculated to do good in strengthening the friendly relations between the two countries (*cheers*). He begged, therefore, to thank them most cordially in the name of his country, and to assure them that nothing could be more acceptable to the people of the United States than such sentiments as those which had been so kindly and liberally expressed on this occasion (*cheers*). The noble president had been pleased (said Mr. S.), in allusion to the late negotiations between the two countries, to express a wish that all differences might be satisfactorily adjusted, and peace and concord long continue. In this wish it was hardly necessary for him to say how cordially and sincerely he united, and the pleasure he felt in believing that the wish would be realized. This, he said, fortunately for mankind, was not an age of war. The time had long since passed when hostility was the natural state of man, and peace but a difficult and dangerous experiment. The soldier and the sword, he thanked God, were now no longer the only security for nations. The schoolmaster, and not the warrior, was abroad. Moral power was taking the place of physical force, and the rulers of the world would soon be taught, if they had not learnt it already, that they would have to look for the security of their thrones to moral rather than physical power, and to the virtue and intelligence of enlightened men (*cheers*). In such an enlightened period of the world, when the love of peace and knowledge and Christianity was overspreading the earth, were there, he asked, one Briton or American, one wise or good man, who would not regard a war between two such countries as England and America as one of the greatest calamities that could befall mankind? A war against interest, national honour, the only justifiable cause of war (said Mr. Stevenson)—a war between nations kindred in language and religion, and for what? Not principle, not honour, nor even conquest; but a war to ascertain the geographical line of a treaty of boundary, the legitimate subject of a negotiation and peaceable adjustment (*loud cheers*). Both countries were too wise, he said, to enter into any such war. Neither, he was sure, would feel itself called upon, in vindication of its honour or in defence of its rights, to embark in war. Their best security for peace was in the wisdom and prudence and foresight of the rulers of both countries, and the virtue and intelligence of their people. He, therefore, only spoke the sentiments of the governor and people of the United States when he assured them that America desired peace with all the world, and especially perpetual good understanding with Great Britain, upon terms compatible with the rights and honour of each (*cheers*). The noble duke had therefore done him no more than justice in supposing that he had done everything, officially and individually, to cherish and invigorate the peaceful relations between the two countries, upon the preservation of which, he said, the prosperity and happiness of both nations so essentially depended (*cheers*). He then said that he hoped he should be indulged in interrupting for a moment the flow of their festi-

vity, whilst he noticed very briefly their association, and the benefits it was calculated to bestow on agriculture. He rejoiced, he said, to have it in his power to attend on this occasion. Besides the pleasure he had derived from witnessing, for the two last days, proceedings so congenial with his feelings, it afforded him an opportunity of returning in person his thanks for the honour which had been conferred upon him in deeming him worthy to become an honorary member of such an association. The only regret he felt, however, was that he could not repay such an honour by some corresponding benefit worthy of the society, and of the deep interest he took in its success (*cheers*). In such an assembly it would be needless, he knew, if he were competent, to expatiate upon agriculture, or its benefits to mankind. He begged permission, however, to throw out one or two suggestions, which might not be unworthy of consideration. All concurred in assigning to agriculture a high place in the scale of individual and national interests, though many did not give it the importance it merited, or which it had a right to aspire to. In other words that it was entitled to a much wider scope than was supposed by those who regarded its objects as limited alone to purposes of subsistence. Now a more fallacious opinion could not, he thought, prevail, than to suppose that the responsibilities of agriculture stopped at providing simply food for eaters. Its duties, Mr. Stevenson said, like those of morality, spread beyond the sphere of providing sustenance, into a wide expanse, created by the obligations arising out of the state of society, and was intimately connected with all the great national interests (*cheers*). The support of governments, the encouragement of commerce, the basis of manufactures, the subsistence of the learned professions, and all scientific and mechanical employments, were sustained by this great interest (*cheers*). As an object of universal benefit it should be one of universal patronage. Agriculture, he said, was national property. The whole country one great farm; the inhabitants one great family, in which those who worked least derived the greatest profit. Other classes, then, besides the farmer, have as great an interest as the farmer himself, in as much as the subsistence of those engaged in agriculture were first to be supplied, and then that of the other classes out of the surplus; and, of course, as the surplus was great so would be the gain. Here, then, was a motive, (a selfish one, but not the less strong) why all classes should unite in supporting this great branch of national industry (*loud cheers*). Now, the best mode of doing this is by such associations as the present. By societies for the collection and diffusion of information; the introduction of the best systems and writings of experienced and enlightened men, and by that excitement and emulation, so necessary to all improvement. Science was now admitted to be indispensable to the due success of agriculture. Theory and practice reflected light on each other, and the more so as there was no pursuit in which habit was so unyielding and inveterate as amongst those who cultivated the soil. But he rejoiced in knowing that agriculture was advancing with giant strides under the salutary benefits of science, and especially chemistry and geology. If any man doubted the extent to which science had contributed its aid to agriculture, let him visit England and Scotland. England, which, Mr. Stevenson said, had been denominated the garden of Europe, and justly so. And why? Simply because her whole surface was cultivated on principles which were brought to the test of the

most rigid and exact experiment. Because agriculture was scientifically and philosophically pursued, and because she had such farmers (*great cheers*). Who could go through this great country, and not be delighted and amazed with its agriculture and its rural economy (*cheers*)? If any foreigner wished to know what England really was, he must go to the country, and mix with her farmers and yeomanry (*cheers*). It had been said, by one he believed of the princes of the present reigning family, that the pride of England was in her yeomanry (*cheers*). He re-echoed the sentiment, and, as an agriculturist at home, proud of belonging to such a class (*cheers*). Indeed, next to the proud distinction of being an American citizen, was that of being a cultivator of the soil. It was, indeed, delightful, to witness such an association as this; to see the wise and good, the politician and professor, the public and private man, uniting to uphold this great and good work, and to see charity and peace shedding this holy calm around, refreshing alike to the feelings and intellect (*cheers*). He hoped that the society would prosper. He begged to remind them that upon its wide spreading and far-extending purposes the eyes of Europe and America were fixed with a steady gaze. He trusted there would be no disappointment. Viewed in relation to their own country, it had every motive for support; but viewed in relation to its effects and benefits upon other nations, the motive for exertion and success rose to a far higher and nobler sentiment (*cheers*). It became not the cause (Mr. Stephenson said) of this country, or his, but that of mankind; and who was so poor and sordid in spirit as to think only of himself, or his country, when the great question was, whether the earth should be inhabited and cultivated by enlightened and virtuous and religious men, or by ignorant and debased human beings, and hordes of savages (*great cheering*)? He concluded by repeating his thanks for the great honour and kindness that had been done him, and expressing a wish that the association might fulfil its high purposes, do honour to its framers, and benefit mankind. He sat down amidst great cheering.

"The health of the Duke of Richmond," which was then proposed by Mr. Stevenson, was received with loud acclamations.

The Duke of Richmond: On the present occasion your reception of my name has nearly unmanned me, and I feel incapable of thanking you as I ought. There are feelings of gratitude which it is nearly impossible to express, but I feel that I owe much to being President of the Society, and one of its first founders. Since "war's alarms" have subsided, I have taken every opportunity to meet my brother farmers, and I have attended every place where my voice could be heard, to call on the landowners to do as I did, because I thought if they did not they were depriving themselves of one of the greatest pleasures that a landowner can enjoy; but my meetings have been amongst gentlemen whom I knew and respected, and I felt that they respected me: I now stand before many who perhaps never knew of my existence till they found me President of the Society. I will say that I consider the formation of this Society of great and permanent advantage to all classes in the country. I have never seen or known what there is to prevent our bringing science to bear on agriculture. If we look back for the last twenty years, we shall find the skill and science of our engineers decidedly manifested, and they now run their vessels with such speed of locomotion, that a person can go to New York in fourteen days; and I do not see why we

should not call to our aid that which has been of such benefit to other interests (*Cheers*). I think I may say that the show-yard this morning proved that the farmers of England consider it of great importance to show their stock here; but the show, I will venture to say, has never been surpassed in any country of the world in implements of agriculture—(*Cheers*). I believe in that we have a great advantage, for the implement makers have found it is not enough to show the machines in the yards of their own premises, they all send them here to be looked at by the farmers of England, and to be tried in the field (*Cheers*). This is one great advantage of competition. As a Southdown breeder I agree in giving premiums for sheep; but there is one class which is unexampled, and I will ask any individual to look around this hall, and say whether he ever saw before so goodly a show of the farmers of the country (*Cheers*). I like to see it, because we know they have ever been the foremost in supporting the Throne and in upholding the Constitution (*cheers*), and in doing their duty to the labourers of the land, who look to them for support. I will, as President, beg of you to remember that a man who in war has received a musket ball, has the privilege not to speak too long, and I do this with greater satisfaction, because it cannot in future be drawn into a precedent; for I hope that in future your President will be at all events sound in wind and limb—(*Cheers*). In concluding these few words, you will permit me to say that I knew there are many men much more capable than I am efficiently to have performed the duties of the chair, but I beg to assure you that I defy the country at large to find one more desirous for the prosperity of agriculture, or one more anxious for the welfare of those engaged in its honourable pursuits, or more deeply grateful to the farmers of the country for the manner in which he has been received at their hands, than the individual who begs to assure you that he feels proud in possessing the good opinion of those before him. With a sincere wish that the farmers may flourish, and that their houses may be the abodes of comfort and content, I beg to drink to the health of you and yours (*Cheers*).

The CHAIRMAN called on an eminent individual connected with Ireland for the next toast. He alluded to the Marquis of Downshire (*Cheers*).

The Marquis of Downshire: I obey the President's call with the greatest pleasure, because, having the honour to fill an office in your society, I should ill discharge my duty if I finched on this occasion, and you all look to set an example not only to your neighbours, but to the country, in coming forward to support the excellent objects of the Society. As originators of the society, you have felt it was beneficial to the landlord and the tenant, and that the lower class of society must have an advantage from it; and therefore I concur with the President in the wish and the hope that the labourers of England, Ireland, and Scotland, may derive the comforts and the blessings of the notice of their superiors, which I think will emanate from the rules and regulations of this society (*Cheers*). I am sure, in addressing the landlords and the farmers of England, there will be a response to the sentiment honourable to themselves as well as beneficial to the country. I must say the members of the Universities of Oxford and Cambridge have particularly distinguished themselves in support of this society, and I beg to propose to you "The health of the Master and Fellows of Downing College"—(*Drunk with cheers*).

The MASTER of DOWNING COLLEGE: In rising

to thank you for the great honour you have conferred on me, by the gratifying manner in which you have received my name. I cannot but feel conscious that I am standing before an assembly that represents the great permanent interest of the realm. I see before me the landlords and tenants not of England only, but of Great Britain—I see around me representatives, not of Old England only, but of New America, and others who have connexion with foreign countries, which makes them the representatives of the world at large; and I feel proud that I can contribute in the smallest degree to the furtherance of those objects which we cannot but look on as being of national importance; for when the first movement of this society took place, I confess that it appeared to me it was the precise thing the agricultural interest wanted. There were throughout the realm a vast number of persons who possessed great insight into the principles of agriculture, experimental and theoretical knowledge, but there was wanting a scientific connexion of the scattered elements by which they should be brought into the form of a living whole. This society was calculated to effect that, by bringing about a combination of the knowledge of the practical man with the studies carried on within the walls of the building in which we are now assembled; and there can be no doubt of the truth of the adage which says, "He is a great benefactor of his country who makes two blades of grass grow where one grew before"—(*Cheers*).

The noble PRESIDENT then proposed "the Cambridge Committee," and thanks to them for their exertions (*Cheers*).

The Earl of HARDWICKE, who was received with great cheering, returned thanks. He had not attended much to the duties of the offices he had filled, and he considered much praise was due to Mr. Empson, to whom they were indebted for the use of land, and with the use of grain, which had enabled them to witness the operation of those implements which were yesterday exhibited. It was a gratifying reflection that so many parties could be called together in a manner like the present, utterly forget political strife. While such a feeling existed among the landholders and farmers of the kingdom, this country could never be broken up by any party. It was satisfactory to find that a feeling prevailed amongst the farmers of the country opposed to war, and he knew of no employment which was more beneficial to the kingdom than that by which the landholders were induced to live in the country where their property was situate, and to make themselves productive of the public benefit (*Cheering*). It now became his duty to propose a toast. He was not much acquainted with the Highland Society, but he knew this, that it had existed many years, and was the principal means of forwarding that success to their own Society, which they had that day met to celebrate. He proposed "Success to the Highland Society" (*Loud cheers*).

THE CHAIRMAN.—As President of this Society, I call upon Sir James Graham to return thanks.

SIR JAMES GRAHAM was also received with loud cheering. Until he entered the room he had not the slightest notion that he should have been called on to address the meeting that evening. Had he had notice he might have been able to address the meeting with more precision, but he could assure them that he did so with honest and heartfelt sincerity for the manner in which his health in connexion with the Highland Society had been received. He must first express his regret, that Scotland should on this occasion be represented by one so unworthy as he was (*No, no*). As an agriculturist he thought not

a half-bred but a thorough-bred Scot should have been produced; and he thought so the more when he saw their chair occupied by an hereditary chieftain, the representative of the noble house of Gordon (*Cheers*). A soldier too, who had fought and bled in the defence of his country (*Cheers*). The Duke of Gordon had been the first to form the Highland Society in Scotland, whilst their President that day had been principally instrumental in forming the English Association. He (Sir James) was delighted to witness the progress of this Society, which appeared to have followed the rules of the Highland Society, and was characterised by a total absence of party politics, and a determination to meet only for the cultivation of knowledge, and an interchange of experience (*Cheers*). Pursuing this course, he had not the slightest hesitation in pronouncing that the Society would succeed in the object which they had at heart. It is said that an admixture of soils produces fertility; and a mixture of all classes gives solidity and strength to the Society (*Cheers*.) It is that which constitutes the greatness and the boast of the happy land we inhabit, and I am sure in no part of the United Kingdom will exertions be wanting to furnish to the people at the cheapest cost, a sure and constant supply of the bread they eat (*Cheers*).

The noble CHAIRMAN then called on Dr. Buckland to propose the next toast.

Prof. BUCKLAND then rose, and was warmly received. He said, My Lord Duke, I duly and highly appreciate the compliment that has been paid to me, or rather to the offices I have the honour to hold as President of the Geological Society of London, and Professor of Mineralogy and Geology in the University of Oxford, in consigning to me the duty which I joyfully undertake, of proposing the healths of the Professors of the University of Cambridge. I rejoice in every occasion of contributing my humble endeavours to promote the objects of this great National Society, which I deem to be fraught with benefits of inestimable importance to the agricultural interest, and as tending rapidly to do away the reproach under which the farmers of England have so long laboured, that they alone have been tardy to appreciate and apply to their profit the numerous discoveries of modern science, whilst the manufacturers have been prompt to avail themselves of every discovery in chemistry or mechanics, and have by such means accumulated wealth to an incalculable amount. The just reproach I allude to is on the point of being speedily and for ever annihilated through the instrumentality of this Society; partly by presenting to assembled thousands at meetings like those of this morning, the results of science practically applied to the breeding of stock and construction of agricultural implements, and still more effectively by imparting to every farmer in the nation through the medium of the journal of this Society, the methods of conducting the most approved experiments for the amelioration of the land. In the first memoir of this journal, your President elect (Mr. Pusey) has most ably and accurately depicted the defects and desiderata in the present systems of British agriculture, and shown how many of them may be supplied by the application of the discoveries of science; and now that in this publication you have a vehicle wherein the results of every agricultural improvement may be faithfully recorded, experiments of the highest value, the memorial of which, had they been made in times past, would have perished together with their author, unheard of beyond the limits of the village in which they were conducted, will no longer fail to be

duly appreciated, and rapidly disseminated over the world. The present meeting has offered me three practical illustrations of the service this Society and its Journal may render by such rapid dissemination of valuable agricultural information. 1st. Mr. Pusey was yesterday informed by an occupier of land near the scene of our experiments on ploughing, that in the vicinity of this field there runs a narrow tract of peculiar excellence for producing seed wheat which is known all over Cambridgeshire and the adjoining counties by the name of Burwell wheat. I have little doubt this tract of land lies on certain strata beneath the chalk, which although near Cambridge, they are but a few feet thick, are known by geologists to occupy a similar place (but usually in much greater quantity), between the chalk formation and the gault clay, and to extend over a considerable portion of the south-east of England, at the base of the great encampments of the chalk hills; and it is probable that the same capacity for producing good seed wheat, may accompany this peculiar series of strata, throughout their whole extent. 2nd. I was told this morning by Lord Hatherton that in the counties of Northumberland, Nottingham, and Hants., extraordinary success has been lately found to attend the culture of Italian rye grass as fodder for sheep, these animals selecting it exclusively from other plants sown with it, and thriving wonderfully upon such food—that in the case of a square piece of land, sown exclusively with Italian rye grass, and having on its margin common clover, the Italian grass alone was eaten, to the neglect of the surrounding clover, so that the field resembled a velvet carpet surrounded by a coarse fringe of wool. I also learn from Mr. Rodwell, that at Alderton, near Woodbridge, in Suffolk, he sowed this grass, last year, on three kinds of soil, resting severally on the sandy, and calcareous, and clay strata of that county, and had on each an incredibly large amount of produce, which was greedily eaten by cattle of every kind; and that he is preparing to have a hundred acres more of it next year. It is of vast importance to ascertain the natural composition of the soils on which the Italian rye grass will thrive best, and to disseminate this information as speedily as possible to the agriculturists of England through the medium of our journal. It is important also to observe what its effects will be upon the crops succeeding it. 3. We have witnessed the facilities with which the subsoil plough may be applied to improve the productiveness of the surface; and now that their general use may be considered as almost certain to be adopted, how important is it for the farmer to be informed by the geologist what the exact nature and quality of the respective subsoils may be, into which the plant will thus be enabled to send down its roots; how valuable is the information conveyed by an engraving I hold in my hand, representing, on the authority of an experienced surveyor, Mr. Badcock, the roots of wheat that grew in Oxfordshire, some years ago, and were found to penetrate to a depth of four and five feet, in a soil that admitted of such descent; and how important is it to the English agriculturist to know that there is a laboratory in London, in the Museum of Economic Geology, attached to her Majesty's Board of Woods and Forests, in Craig's Court, Charing Cross, to which any individual may send one pound of any soil of which he wishes to know what are the ingredients, and for a fixed fee (I believe of twenty shillings) obtain an exact analysis of the same, conducted by Mr. Richard Phillips, whose name has long been in the first rank of the analytical chemists of Europe. It is by methods like those

just cited, that occasions are now offered to the agriculturists of England of carrying out the spirit of the motto stamped on the seal of our Society, by uniting "Practice with Science," and it was well befitting so great an object that our first meetings should be holden in the ancient Universities of the land, of whose special duty it is no small part to give instruction from the chairs of Professors of Science, to a large proportion of the rising generation who will, hereafter, become landed proprietors; and to no event of my academic life do I look back with more pure delight than to the hearty, though imperfect, service which it became my duty to offer to the society, on the occasion of their first meeting. I rejoice, also, that I am permitted to attend the present meeting in the sister University, and to witness the sympathy which is felt at Cambridge, no less than Oxford, in the great and important proceedings of the Royal English Agricultural Society. It was noticed by the Vice-Chancellor of Oxford, last year, that a Professorship of Rural Economy would speedily be there established, in the person of the Professor of Botany, and endowed from funds bequeathed by a former Professor of Botany, Dr. Sibthorpe, for the purpose, first, of publishing his *Flora Græca*, and secondly, of annexing to the chair of Professor of Botany the further duty of Lecturer on *Rural Economy*. The present year having terminated the publication of the *Flora Græca*, Dr. Daubeny has become the first occupier of the Agricultural chair, and is now setting out on an extensive tour through Europe, to study the actual state of Agriculture among our continental neighbours, and collect materials for a library, consisting of works on agriculture, which Dr. Sibthorpe has ordered to be purchased annually, with the surplus of his funds beyond the sum appointed for the salary of the Professor. From the labours of Dr. Daubeny, thus called into activity, the Agriculture of England may speedily derive advantages of no small amount. The University of Cambridge has, I believe, no similar endowment bearing thus directly upon practical agriculture, but the mathematical tendency of its predominating studies is eminently calculated to qualify its scholars for the important service of improving the mechanism of agricultural implements, by diminishing the loss of force by friction, and suggesting the most advantageous application of the mechanical powers, in every detail of their construction; so that, in no long time, we may expect to see universally adopted throughout the land, such improved implements and machinery as will enable two horses to perform with ease the work that is now with difficulty performed by four. The University of Cambridge possesses, also, in its professor of Botany, Mr. Henslow, a distinguished vegetable physiologist, pre-eminently qualified to prepare, as he has engaged to do, a systematic table of instructions to be followed by individual cultivators in distant parts of the country, for the purpose of collecting a series of results that may lead to a sound theoretical understanding of the principles which regulate the growth of vegetables, and of the influence exerted thereon by meteoric causes, by soil, and by animal, vegetable, and mineral manures. Professor Cumming is not less ready to contribute from the rich resources of his long acknowledged skill in chemistry, towards the application of this important science to improvements in agriculture. My friend and colleague, Professor Sedgwick, who deeply deplores his inevitable absence on this occasion, will joyfully co-operate with me in pointing out the almost innumerable, but now neglected sources, from which an exhaustible supply of mineral manure

may be derived for the permanent improvement of barren lands; not to the *exclusion*, or in preference to the animal and vegetable manures, as was erroneously imagined by a gentleman who spoke upon the subject yesterday, but as *auxiliary* to them, and *additional*, and as necessary, precursors in the case of thousands of acres, now absolutely barren for lack of having added to them portions of subjacent or adjacent strata, composed of materials different from those at the surface, the addition of which would produce that *admixture* of the elementary earths of flint and clay and lime, which is indispensable to give the greatest fertility to soils. Lastly, Professor Whewell, the historiographer of all sciences, and successful cultivator of so many, is panting for the occasion, now so near at hand, of dedicating another volume to the philosophy of the science of agriculture, as it will henceforth be practised by the members of the Royal Agricultural Society of England. [The learned Professor closed his speech amidst great applause, which indeed had greeted him during his whole delivery.]

The Duke of Richmond said he had now to introduce to their notice Professor Whewell, whom the Council had selected to respond to the toast just proposed.

Professor WHEWELL said, he had now to appear before them as the representative of the Professors of the University of Cambridge. He came thus forward in obedience to the wishes of the Council, but, desirous as he was to shew his respect to the meeting for the honour he had received, he felt that he himself would be incapable to contribute much to the success of the society. As the Professor of Moral Philosophy, his pursuits necessarily prevented him from immediately aiding the great body he saw around him; but he could assure them that, in the University of Cambridge, the Professors, as a body, were fully capable of advancing the interests of the society; they were second to none in the desire, and inferior to few in ability, to aid the great cause the society had in view. (*Cheers.*) In Chemistry, they had Professor Cumming, whose powers to benefit agriculture were of the first order. In Geology, they had Professor Sedgwick, than whom there could scarcely be found one more qualified to teach the farmer what it was necessary for him to know respecting the different soils it might be his lot to cultivate. In Botany, they had Professor Henslow, already known to many, and likely to be more known to them. In Comparative Anatomy, a branch of science of the highest importance to those who wished to promote the improvement of the breed of cattle, they had Professor Clark, who had already done much in his department, by collecting the splendid museum now possessed by the University, and which, if there were any present who had not seen it, he most earnestly invited them to inspect it.—That Professor Willis, the Professor of Mechanics, was well adapted for the office he held he would illustrate by the fact, that, in visiting the implements shewn that day, he had pointed out to him, as one of the great advantages of a machine, that the toothed wheels were made according to the rule laid down by the Professor of Mechanics in the University of Cambridge. Thus, in this instance at least, a Professor of the University of Cambridge was successfully aiding the agriculturist in improving the means he had to benefit himself and his country. He felt assured that his most sanguine anticipations would be more than realized, if the practical agriculturist would co-operate with and carry into effect the suggestions of those who devoted their lives to theoretically carrying out the principles of science.

As the Professor of Moral Philosophy, his duty was peculiarly to inculcate the principles of probity, and the duty of one to another; and, in doing this, he could not shut his eyes to the fact, that if one class has distinguished itself more than another by the possession of these high principles, it has been the agricultural, who, on all occasions seems to have considered that their own property and that of their country was involved in the support of all that was just and holy—all that partook of the noblest sentiments we cherish—all that was characteristic of our national religious feeling.

The President then called the attention of the meeting to the Duke of Rutland, who was deputed to give the next toast.

The Duke of RUTLAND, who spoke in a very low tone, we understood to say, that he had heard a remark, in reference to the society, that they wanted "a clear stage and no favour;" he was somewhat in a different predicament, for he had "a clear stage," and he wished for "the favour" of the meeting. One hon. gentleman had spoken of his alarm at the suddenness of the call which had been made upon him, but that gentleman was accustomed to public speaking; what then must be his (the Duke of R's.) condition, who was totally unaccustomed to such displays, and who had scarcely ever attempted to address a meeting composed of one-tenth of the number present. He could not survey the meeting before him without the greatest gratification, and he was anxious to express his joy, at recollecting that he had been one of the first who had enrolled himself a member of the society. (*Cheers.*) He would conclude by expressing to the meeting, that, in all they undertook, they might rely upon his cordial concurrence; and, expressing his belief that there was no occupation more honourable than that of agriculture, he would propose the toast assigned to him, namely, "the health of the Stewards of the Yard, and Judges of the Shew."

Earl SPENCER then rose from the table below the President, to return thanks for himself and his colleagues for the honour conferred upon them, and said that, if the exertions of himself, with Mr. Pym and Mr. Druce, were such as to render the shew satisfactory, any trouble it might have cost them was amply repaid. The office of the Judges was one of great responsibility, and was, moreover, a very unthankful office; to them, therefore, the society ought to feel greatly obliged, and though universal satisfaction could not be anticipated from their decisions, he felt bound to say, that, having been present himself during the whole time of the examination, it was impossible that more attention could be paid, or greater exertions made, to approach the consummation wished—that of doing justice to all. He could not conclude without expressing his belief, that the institution of which they were members was calculated to be of the greatest benefit to the Agricultural interest—it was *the thing* wanted, and he was sanguine as to the results. The noble Earl then eulogised Sir Robert Peel for the great interest he had taken in the formation of the society, and also in the carrying out its objects, and concluded by proposing the toast assigned to him—"The Mayor and Corporation of Cambridge."

The Duke of Richmond then rose to propose "The Agricultural Labourer," and having pointed out their patience under difficulties, and that one object of the society was to improve their condition, concluded by requesting the meeting to drink the toast with three times three. (*Great cheering.*)

HENRY HANDLEY, Esq., M.P., having been appointed to propose the next toast, spoke as follows:—My Lord Duke and gentlemen, I have been honoured with the pleasing task of introducing to you the name of the President elect, Mr. Pusey. It is a satisfaction to me to feel, that however I may be deficient in language to do justice to the toast, I am fortunately in the position of bearing a plain, unvarnished testimony to the claims that gentleman has on the favourable consideration and gratitude of this society, and to the high honour which has been unanimously awarded to him of presiding over you during the ensuing year. When this society first struggled into existence, it received the zealous and fostering support of Mr. Pusey; and when it was found desirable to publish a Journal, setting forth our objects and intentions, and to present to the public in proper form the communications of those who were more accustomed to labour in the field of nature than the field of letters, Mr. Pusey did not hesitate to quit for a time those higher walks of literature and of science in which he had attained a distinguished position; and to bring the powers of his comprehensive mind, and the assiduity of his habits to the laborious task of editing your Journal.

Mr. PUSEY, who was heard to great disadvantage in consequence of the breaking up of the meeting, observed, when he had unexpectedly been called upon to fill the office of President of the society, he should not have felt justified in accepting that office if Lord Spencer had not thought he would be able to discharge it. That at that hour, and after the speech, in which Sir Robert Peel had shewn that there is no subject, to which he turned his mind, of which he did not at once see the main bearings, and none which he entered upon that he did not adorn, it would be presumptuous in him (Mr. P.) to say one word more upon their objects, indeed he feared that the growing numbers of the society, as they now exceeded the power of his own voice, would soon be too much for voices far stronger than his. He would only, therefore, express his hope, that, as they had already twice gathered within the hospitable walls of the two Universities, and, following out their own objects, had found time to contemplate the noble buildings, within which so much was done for preserving the moral strength of the country, so they might rally in the next year at Liverpool, where they would view that shipping and those vast docks, which contributed so much to our political strength.

The noble Chairman and his immediate friends then left the Pavilion, and thus closed one of the most imposing spectacles ever witnessed.

AWARD OF PRIZES.

CAMBRIDGE MEETING, JULY 14, 1840.

Stewards: the Right Hon. the Earl Spencer, of Althorp, near Northampton; F. Pym, Esq., of the Hasells, near Biggleswade; and Mr. Druce, of Ensham, near Oxford. Director of the yard, Mr. Humphrey Gibbs, Hon. Secretary, Smithfield Club.

CATTLE.

CLASS I.—SHORT-HORNS.

Judges: Mr. John Wright, Mr. Eaton Clarke, and Mr. W. Smith.

The best Short-horned Bull, calved previously to the 1st of January, 1838.

Prize of 30 sovereigns, adjudged to Mr. Paul, of Pentney, Norfolk, for his 4 years and 3 months old

Durham Bull, bred by Mr. Topham, of West Keal, Lincolnshire.

The other competitors were—The Rev. D. Gwilt, of Icklingham, Suffolk; Mr. Adeane, of Babraham, Cambs.; Mr. J. Beasley, of Chapel Brampton, Northamptonshire; Mr. Barnard, M.P., of Gosfield Hall, Haleslad; Rev. E. Lindsell, of Broom Hall, Beds.; Mr. T. Bates, of Kirkleavington, Yorkshire.

The best Bull, calved since the 1st of January, 1838, and more than one year old.

Prize of 15 sovereigns, adjudged to Mr. R. M. Jaques, Richmond, Yorkshire, for his one year and ten months old short-horned Bull, bred by Mr. Parkinson, of Babworth, Notts.

The other competitors were—Mr. Montfort Strickland, of Guilden Morden, Cambs.; Mr. Robert Ayres, of Girtford, Beds.; Rt. Hon. C. Arbuthnot, Woodford, Northamptonshire; Mr. J. Feast, of Upwell Fen, Cambs.; Mr. George Carrington, jun., of Great Missenden, Bucks.; Mr. A. Scott, of Walton, Surrey; Mr. J. Harradine, of Needingworth, Hunts.; Mr. Thomas Clarke, of Wimbish, Essex; Mr. Henry Cleeve, of Rettendon, Essex; Messrs. I. C. Etches, of Liverpool, and T. Foreman, of Cressage, Salop.

The best short-horned Cow, in Milk.

Prize of 15 sovereigns, adjudged to Mr. T. Bates, of Kirkleavington, Yorkshire, for his 6 year old short-horned Cow, bred by himself.

The other competitors were—The Earl of Hardwicke, Wimpole, Cambs.; Rt. Hon. Charles Arbuthnot, of Woodford, Northamptonshire; Mr. Henry Beaufoord, of Holmes, near Biggleswade, Beds.; The Marquis of Exeter, Burghley Park, Northamptonshire; Mr. Jonas Webb, Babraham.

The best Short-horned in-calf Heifer, not exceeding three years old.

Prize of 15 sovereigns, adjudged to the Right Hon. C. Arbuthnot, of Woodford, Northamptonshire, for his 2 year and 3 months old Durham heifer, bred by himself.

The other competitors were—Mr. E. Calvert, of Hudson, Herts.; Mr. Jonas Webb, of Babraham, Cambs.; Messrs. Etches and Foreman, of Liverpool.

The best Short-horned Yearling Heifer.

Prize of 10 sovereigns, adjudged to Mr. R. M. Jaques, of St. Trisians, Richmond, Yorkshire, for his one year and ten months old short-horned yearling heifer, bred by the Earl of Carlisle.

The best Hereford Bull, calved since the 1st of January, 1838, and more than one year old.

(No entry.)

The best Hereford Cow in milk.

Prize of 15 sovereigns, adjudged to Sir H. Hoskyns, Bart., of Hereford, Herefordshire, for his 5 years old Hereford Cow, bred by himself.

The best Hereford in-calf Heifer, not exceeding three years old.

Prize of 15 sovereigns, adjudged to Sir H. Hoskyns, Bart., of Hereford, Herefordshire, for his 2 years and 5 months old Hereford Heifer.

The other competitor was—Mr. F. Hower, of Hereford.

The best Hereford yearling Heifer.

Prize of 10 sovereigns, adjudged to Mr. F. Hower, of Hereford, for his 1 year and 11 months old Hereford yearling Heifer.

The best Hereford Bull Calf.

(No entry.)

CLASS III.—DEVONS.

Judges.—Mr. Wyndham, Mr. Stace, and Mr. G. Smythies, of Leominster.

The best Devon Bull, calved previously to the 1st of January, 1838.

Prize of 30 sovereigns, adjudged to Mr. W. Porter, of Hembury Fort, Buckwell, Devonshire, for his 3 years and 2 months old Devon bull, bred by Mr. Quartly.

The other competitors were—Mr. T. Reynolds, of Thoverton, Devon; Mr. G. Salter, of Crewkerne, Somerset; the Duke of Norfolk; Lord Western.

The best Devon Bull, calved since the 1st of Jan. 1838.

Prize of 15 sovereigns, adjudged to his Grace the Duke of Norfolk, of Fordham, for his Grace's 1 year and 5 months old Devon bull, bred by his Grace.

The other competitors were—Mr. G. Turner, of Barton, near Exeter, Devon; Lord Western.

The best Devon Cow in Milk.

Prize of 15 sovereigns, adjudged to Mr. Thomas Umbers, of Wapenbury, Warwick, for his 5 years old North Devon Bull, bred by the late Mr. Talbot, of Temple Guiting, Gloucestershire.

The other competitors were—Mr. T. Stephens, of Whitelackington, Somerset; Mr. James Davy, of North Molton, Devon.

The best Devon in-calf Heifer, not exceeding 3 yrs. old.

Prize of 15 sovereigns, adjudged to Mr. G. Turner, of Barton, near Exeter, for his 2 years and 10 months old North Devon Heifer, bred by himself.

The other competitors were—Mr. G. Turner, of Barton, near Exeter, Devon; Mr. Thomas Stephens, of Whitelackington; the Duke of Norfolk; Lord Western.

The best Devon yearling Heifer.

Prize of 10 sovereigns, adjudged to Mr. G. Turner, of Barton, near Exeter, for his 1 year and 4 months old North Devon yearling Heifer, bred by himself.

The other competitors were—Right Hon. Lord Western, of Felix Hall, Devon; Mr. Thomas Stephens, of Whitelackington.

The best Devon Bull Calf.

Prize of 10 sovereigns, adjudged to Mr. Thomas Stephens, of Whitelackington, Somerset, for his 5 months old Devon Bull Calf, bred by himself.

The other competitors were—Lord Portman, of Bryanston, Dorsetshire; the Duke of Norfolk.

CLASS IV.—CATTLE OF ANY BREED OR CROSS,

Not qualified for Classes 1, 2, 3.

Judges.—Mr. — George, Mr. John Ellman, and Mr. John Hall.

The best Bull, calved previously to the 1st of Jan. 1838.

Prize of 30 sovereigns, adjudged to Mr. J. Putland,

of West Firle, Sussex, for his 3 years and 2 months old pure Sussex Bull, bred by Mr. Putland.—[Mr. S. Crisp's 2 years and 10 months old Durham Bull was disqualified, the Stewards being of opinion that it is of the short-horn breed.]

The other competitors were—Mr. H. Overman, of Weasenham, Bucks; Mr. T. Crisp, of Gedgrave, Suffolk; Mr. R. Johnson, of Burwell, Cambs.

The best Bull, calved since the 1st Jan. 1838.

Prize of 15 sovereigns, adjudged to Sir E. Kerrison, Bart., M.P., of Oakley Park, Suffolk, for his 1 year and 4 months old Suffolk Bull.

The other competitors were—Mr. J. Hillman, of Ringmer, Suffolk; and the Duke of Rutland.

For the best Cow in Milk.

Prize of 15 sovereigns, adjudged to Mr. J. Putland, of West Firle, Sussex, for his 5 years and 2 months old pure Sussex Cow.

The other competitors were—The Duke of Rutland, and Lord Braybrooke.

The best in-calf Heifer not exceeding 3 years old.

Prize of 15 sovereigns, adjudged to Mr. J. Putland, of West Firle, Sussex, for his 2 years and 3 months old in-calf Heifer, bred by himself. [No other competitor.]

The best yearling Heifer.

Prize of 10 sovereigns, adjudged to Mr. J. Putland, of West Firle, Sussex, for his 1 year and 3 months old pure Sussex yearling Heifer.

The other competitor was—Sir E. Kerrison, Bart.

The best Bull Calf.

Prize of 10 sovereigns, adjudged to Mr. J. Putland, of West Firle, Sussex, for his 5 months old Bull Calf, of the pure Sussex breed. [No other competitor.]

CLASS V.—HORSES.

Judges, Mr. G. Clarke, of Barnaby Moor; Mr. C. Bowman, of Greatford, Market Deeping.

The best Cart Stallion.

Prize of 30 sovereigns, adjudged to Mr. John Bell, of Welton-le-Wold, Lincolnshire, for his 12 years old cart stallion, bred by by Mr. J. Adams, of Landbeach, Cambs.

The other competitors were—Mr. C. Plant, of Farnham, Suffolk. Mr. J. Ivatt, of Cottenham, Cambs. Mr. T. Webb, of Hildersham, Cambs. Mr. John Biddall, of Caxton, Cambs. Mr. E. Ellis, of Soham, Cambs. Mr. R. Daintree, of Hemingford Abbots, Hunts. Mr. W. Davies, of Radwinter, Essex. Mr. R. Johnson, of Burwell, Cambs. Hon. Captain Spencer, of Althorp, Northamptonshire. Mr. E. B. Washlourne, of Greenham, Berks. Mr. W. Nix, of Somersham, Hunts. Mr. T. N. Catlin, of Chillesford, Suffolk. Mr. H. Crosse, of Boyton Hall, near Stowmarket, Suffolk. Mr. W. Worledge, of Cresting St. Peter's, Suffolk. Mr. Francis Kerr, of Raydon, Suffolk. Mr. T. Crisp, of Gedgrave, Suffolk. Mr. J. Hayden, of Arrington, Cambs.

The best Cart Mare and Foal.

Prize of 15 sovereigns, adjudged to Mr. T. N. Catlin, of Chillesford, Suffolk, for his cart mare and foal, bred by Mr. Cooper, of Friston, Suffolk.

The other competitors were—Mr. J. Webb, of Horseheath, Cambs. Lord Braybrooke, Audley End, Saffron Walden, Essex. Mr. R. Daintree, of Hemingford, Abbots, Hunts. Mr. H. Cross, of Boyton Hall, Stowmarket.

*The best Stallion for breeding Hunters, Carriage-horses, or Roadsters, which shall have served Mares during the season of 1840, at a price not exceeding 3*l.* each.*

Prize of 30 sovereigns, adjudged to Mr. John Reynolds, of Wisbech, Cambs., for his 8 year old stallion, bred by Mr. J. O. Taylor, of Flixton.

The other competitors were—Mr. E. Pells, of Culpho, Suffolk. Mr. A. Hammond, of Westacre, Norfolk. Mr. W. Lacy, of Panton, Lincolnshire. Mr. J. Cullam, of Ipswich, Suffolk. M^{rs} H. Middleton, of

Ridlington, Oxon. Mr. C. W. Minet, of Brasted, near Seven Oaks. Mr. J. Shippey, of Horseheath, Cambs.

SHEEP.

CLASS VI.—LEICESTERS.

Judges, Mr. John Manning, Mr. Thomas Chapman, of Stoneleigh, Coventry, and Mr. W. Pratt, of Newfield, Warwick.

The best Shearling Leicester Ram.

Prize of 30 sovereigns, adjudged to Mr. Samuel Bennett, of Bickering's Park, Beds., for his 16 months old pure Leicester Shearling Ram, bred by himself.

The second best Shearling Leicester Ram.

Prize of 10 sovereigns, adjudged to Mr. Samuel Bennett, of Bickering's Park, Beds., for his 16 months old Leicester shearing ram, bred by himself.

The other competitors were—Mr. E. Dawson, of Ingthorpe, Rutlandshire; Mr. Robert Faldor, of Lidlington Beds; Mr. Thomas Inskip, of Marston, Beds; Mr. W. Umbers, jun., of Wappenbury; Mr. J. Bennett, of Tomsford, Beds; Mr. W. F. Hobbs, of Marks Hall, near Coggeshall; Mr. W. Salisbury, of Dordon, Warwickshire; Mr. John Earl, of Earls Barton, Northamptonshire; Mr. T. E. Pawlett, of Tinwell, Rutlandshire, and Mr. G. Turner, of Barton, Devon.

The best Leicester Ram of any other age.

Prize of 30 sovereigns, adjudged to Mr. T. E. Pawlett, of Tinwell, Rutland, for his two years and 4 months old Leicester ram, bred by himself.

The other competitors were—Mr. W. F. Hobbs; Mr. John Bodley, of Stockley, Pomeray, Devonshire; Mr. J. Earl, of Earls Barton; Mr. E. Dawson, of Ingthorpe, Rutland; Mr. T. Inskip, of Marston, Beds; Mr. M. Crisp, of Letheringham, Suffolk; Mr. J. G. Watkins, of Woodfield House, Worcester; Mr. J. Bennett, of Tomsford, Beds; Mr. W. Umbers, of Wappenbury, Warwick; Mr. E. Lythall, of Foleshill, Warwickshire; Mr. R. Bedger, South-hill, Beds; Mr. T. E. Pawlett, of Tinwell, Rutland; Mr. George Turner, of Barton, near Exeter, Devon; Mr. W. Golborne, of Witcham, Cambs.

The best pen of Five Leicester Ewes, with their Lambs.

Prize of 10 sovereigns, adjudged to Mr. T. Inskip, of Marston, Beds., for his pen of five Leicester Ewes, with their Lambs.

[No competitor.]

The best pen of Five Leicester Shearling Ewes.

Prize of 10 sovereigns, adjudged to Mr. W. Pawlett, of Barnack, Northamptonshire, for his pen of 16 months old new Leicester shearing Ewes, bred by himself.

The other competitor was—Mr. H. Beauford, of Holme, near Biggleswade.

CLASS VII.—SOUTH-DOWNS.

JUDGES.—Mr. J. Bevan, of Thornham, Wilts.; Mr. J. Raymond Barker, of Fairford Park, Gloucester; Mr. H. Chamberlain, of Desford, Leicester.

The best Shearling short-woolled Ram.

Prize of 30 sovereigns, adjudged to his Grace the Duke of Richmond, of Goodwood Park, for his Grace's sixteen months old Southdown shearing Ram, bred by his Grace.

The second best Shearling short-woolled Ram.

Prize of 10 sovereigns, adjudged to Mr. T. Crisp, of Gedgrave, Suffolk, for his 16 months old Southdown shearing Ram, bred by himself.

The other competitors were—Mr. H. Overham, Weasenham, Norfolk; Mr. J. Hillman, Ringmer, Sussex; Mr. J. T. Bennet, of Chevely, Cambridgeshire; Mr. G. Drake, of Manor Farm, East Tytherley, near Stockbridge; Mr. T. N. Cattlin, of Chillesford, Suffolk; Mr. T. Crisp, of Gedgrave, Suffolk; Mr. M. Crisp, of Letheringham, Suffolk; Mr. R. B. Harvey, of Harleston, Norfolk; Mr. S. Shillito, of Barrow, Suffolk; Mr. H. Boys, of Waldershare, Kent; Mr. T. Ellman,

of Beddingham, Sussex; Mr. J. Webb, of Babraham, near Cambridge.

The best short-woolled Ram of any age.

Prize of 20 sovereigns, adjudged to Mr. T. Crisp, of Gedgrave, Suffolk, for his 3 year old Southdown Ram, bred by himself.

The other competitors were—Mr. J. T. Bennet, of Chevely, Cambridgeshire; Mr. E. Lugar, of Hengrave, Suffolk; Mr. E. G. Bernard, M.P., of Gosfield Hall, near Halsted, Essex; Mr. H. Overman, of Weasenham, Norfolk; Mr. J. Hillman, of Ringmer, Sussex; Mr. T. N. Cattlin, of Chillesford, Suffolk; Mr. W. Bryant, of Newmarket, Suffolk; Mr. S. Shillito, of Barrow, Suffolk; Right Hon. Lord Western, of Felix Hall, Essex; Mr. S. Grantham, of Stoneham Lewes, Sussex; the Hon. H. W. Wilson, of Diddington, Norfolk; Mr. J. Harris, of Hinton, Berks.; Mr. H. Boys, of Waldershare, Kent; his Grace the Duke of Richmond, of Goodwood, Sussex; Mr. Jonas Webb, of Babraham, Cambridgeshire.

The best Pen of 5 short-woolled Ewes, with their Lambs.

Prize of 10 sovereigns, adjudged to Mr. J. Webb, of Babraham, Cambs., for his pen of Southdown Ewes, and their Lambs, bred by himself.

The other competitors were—Mr. J. T. Bennet, of Chevely, Cambridgeshire; Mr. H. J. Adeane, of Babraham, Cambs.; Mr. Jonas Webb, of ditto.

The best Pen of 5 short-woolled shearing Ewes.

Prize of 10 sovereigns, adjudged to Mr. J. Webb, of Babraham, for his pen of Southdown shearing Ewes, bred by himself.

The other competitors were—the Hon. W. Wilson, of Diddington, Norfolk; Mr. J. Hudson, of Castle Acre, Norfolk; his Grace the Duke of Richmond, of Goodwood, Sussex; Mr. J. Webb, of Babraham, Cambs.; Mr. H. J. Adeane, of ditto; Mr. H. Overman, of Weasenham, Norfolk; Mr. T. Crisp, of Gedgrave, Suffolk; his Grace the Duke of Norfolk, of Farnham, Suffolk; Mr. S. Webb, of Babraham, Cambridgeshire.

The Judges commended this class in general.

CLASS VIII.—LONG-WOOLLED SHEEP,

Not qualified to compete for Class 6.

Judges—Mr. Hindley, and Mr. J. Elliot, of Chapel Brampton.

The best shearing long-woolled Ram.

Prize of 30 sovereigns, adjudged to Mr. Large, of Broadwell, for his long-woolled shearing ram, 16 months old, bred by himself.

The second best shearing long-woolled Ram.

Prize of 10 sovereigns, adjudged to Mr. J. Harradine, of Needingworth, Hunts., for his 16 months old long-woolled shearing ram, bred by himself.

The other competitors were—Mr. J. Fallagar, of Milton, next Sittingborne, Kent; Mr. R. Dawson, of Withcall House, Lincolnshire; Mr. J. Harradine, of Needingworth, Hunts.; Mr. E. Dawson, of Ingthorpe, Rutlandshire.

The best long-woolled Ram of any other age as above.

Prize of 30 sovereigns, adjudged to Mr. C. Large, of Broadwell, Oxon, for his three years and four months old New Oxfordshire long-woolled ram, bred by himself.

The other competitors were—Mr. W. Gale, of North Farnbridge Hall, Essex; Mr. W. Gobbarn, Witcham, Cambridgeshire; Mr. R. Dawson, of Withcall House, Lincolnshire; Mr. E. Dawson, of ditto; Mr. E. Dawson, of Ingthorpe, Rutlandshire; Mr. J. Harris, of Hinton, Berks; Mr. J. Haradine, of Needingworth, Hunts; Mr. C. Large, of Broadwell, Oxon; Mr. R. Dudding, of Pantons, Lincolnshire.

The best Pen of 5 long-woolled Ewes and their Lambs.

Prize of 10 sovereigns, adjudged to Rev. J. Lintot, of Hemingford Grey, Hunts., for his Lincoln and Leicester ewes, with their lambs, bred by Mr. R. Daintree, of Hemingford.

The other competitor was—Mr. J. Linton, of Hemingford Grey, Hunts.

[This statement is taken from the printed award, but it appears to us there must be some error.—*Ed. M.L.E.*]

The best Pen of 5 long-woolled shearling Ewes.

Prize of 10 sovereigns, adjudged to Mr. E. Smith, of Charlbury, Oxon, for his pen of 15 months old, improved Oxfordshire shearling ewes, bred by himself.

The other competitors were—Mr. R. Pratt, of Spelsbury, Oxon; Mr. J. Harradine, of Needingworth, Hunts.

CLASS IX.—PIGS.

Judges, Mr. Wilkie and Mr. Oakden.

The best Boar.

Prize of 10 sovereigns, adjudged to Mr. Barnard, M.P., of Gosfield Hall, Essex, for his 1 year and 4 months old boar, of the improved Essex breed.—[This animal is from the stock of Mr. W. F. Hobbs, to whom the next prize is awarded.—*Ed. F.M.*]

The other competitors were, Mr. W. F. Hobbs, of Marks Hall, Essex; Mr. W. J. Norris, of Radwell, Herts; Mr. J. Woodard, of Stanton, Suffolk; Rt. hon. Lord Western, of Felix Hall, Essex; Mr. H. Handley, of Culverthorpe, Lincolnshire; Mr. Thomas Gibbs, of the corner of Half Moon-street, Piccadilly, London; Rev. A. Peyton, of Doddington, Cambs.; Mr. T. N. Catlin, of Chillesford, Suffolk; Mr. R. Ayres, of Guilford, Beds.; Mr. W. Hammond, of Fenstanton, Hunts.

The best Sow.

Prize of 5 sovereigns, adjudged to Mr. W. F. Hobbs, of Mark's Hall, Coggeshall, Essex, for his 3 years old sow, bred by Mr. Francis, of White Colne, Essex.

The other competitors were, Rt. Hon. Lord Braybrooke, of Audley End, Saffron Walden, Essex; Mr. Thomas Gibbs, of the corner of Half Moon Street, Piccadilly, London.

The best pen of 3 Pigs, of the same litter, above 4, and under 9 months old.

Prize of 10 sovereigns, adjudged to Mr. G. W. Kirkby, of Eppingbury, Essex, for his three 36 weeks old pigs, bred by himself.

The other competitor was Mr. T. N. Catlin, of Chillesford, Suffolk.

EXTRA STOCK.—BEASTS.

The most noble the Marquis of Exeter, Burghley Park, Northamptonshire, Durham bull calf, 7 months old, bred by himself; his grace the Duke of Norfolk, a fat Devon heifer; Mr. J. Putland, of Firle Place Farm, Sussex, heifer 4 years old; Mr. W. Bryant, of Newmarket, Suffolk, short-horned bullock, 5 years old commended; Mr. T. Wing, of Thorney Abbey, Cambs., Hereford ox, 4 years old, bred by himself; Mr. R. W. King, Brinkley, Cambs., short-horned heifer, 2 years and 2 months old, bred by Mr. Holland, of Worlaby, Lincoln.; Mr. R. W. Kings, of Brinkley, Cambs., short-horned ox, 4 years and 3 months old, bred by Mr. King, of Hornsby, Lincolnshire; Duke of Norfolk a fat Devon heifer, 54, awarded.

HORSES.

Mr. R. N. Bacon, of Thorp Hamlet, Norwich, chestnut gelding, 3 years old, bred by G. Rising, of Martam, near Yarmouth, Norfolk; Mr. John Warsop, of Alconbury Hill, Hunts., nag horse, 2 years and 1 month old; Mr. W. Batty, of Cambridge, entire Shetland pony; Mr. T. N. Catlin, of Chillesford, Suffolk, cart mare; Mr. Walter Vipan, of the Hermitage farm, Haddington, Isle of Ely, Cambs., gelding, 2 years and 3 months old; Mr. Thomas Teverson, of Great Wilbraham, Cambs., nag mare and foal, the sire of foal belonging to Mr. Read; Mr. Thomas Teverson, of Great Wilbraham, Cambs., nag colt, the sire of foal, belonging to Mr. T. Robinson, of High Wycombe, Buckinghamshire; Mr. Thomas Teverson, of Great Wilbraham, Cambs., 2 fillies, 2 years old, the sire of fillies, property of Mr. T. Robinson, of High Wycombe, Bucks.; Mr.

R. Daintree, of Hemingford Abbots, Hunts., three cart mares, 3 years old, and one cart mare 5 years old, all bred by himself; Mr. Thomas Hall, of Cottenham, Cambridgeshire, cart mare, 6 years and 2 months old, bred by himself; Mr. H. Cross, of Boyton Hall, near Stowmarket, Suffolk, a Suffolk cart mare, 5 years and 6 months old; and a Suffolk cart mare, 6 years and 6 months old.

SHEEP.

The other exhibitions of Sheep were—

Mr. E. Lythall, of Foleshill, Warwickshire, Leicester ram, 4 years and 4 months old, bred by himself; Mr. E. Lythall, of ditto, Leicester ram, 3 years and 4 months old, bred by himself; Mr. Shillito, 3 fat two-shear South-down wethers, bred by himself; Mr. S. Webb, of Babraham, Cambs., shearling Southdown wether, 15 months old, bred by himself; Mr. S. Webb, of ditto, shearling Southdown wether, 15 months old, bred by himself; Mr. S. Webb, of ditto, shearling Southdown wether, 15 months old, bred by himself; Mr. H. J. Adeane, of Babraham, Cambs., 3 wether Southdown sheep, 25 months old, bred by himself; Mr. R. Pratt, of Spelsbury, Oxon, 5 improved Oxfordshire shearling wether hoggets 15 and a-half months old, bred by himself; Mr. W. Umbers, Jun., Wappenbury, Warwick., Leicester shearling ram, 17 months old, bred by himself; Richard Daintree, Esq., of Hemingford Abbots, Hunts.; Hon. H. W. Wilson, of Diddington, Norfolk, Southdown shearling ram, 16 months old, bred by himself; Mr. T. White, pen of long-woolled wether hoggets, 15-and-a-half months old, bred by himself; His Grace the Duke of Norfolk, pen of Southdown wethers; Mr. E. Dawson, 6 rams; Mr. T. E. Pawlett, of Tinivel, Rutlandshire, Leicester shearling ram, 16 months old, bred by himself; Mr. T. E. Pawlett, of ditto, Leicester ram, 5 years old, bred by himself; Mr. T. E. Pawlett, of ditto, Leicester ram, 4 years old, bred by himself; Mr. T. E. Pawlett, of ditto, Leicester ram, 3 years old, bred by himself; Mr. T. E. Pawlett, of ditto, shearling Leicester ram, 16 months old, bred by himself; Mr. S. Shillito, of Barrow, 3 fat two-shear Southdown wethers; His Grace the Duke of Norfolk, pen of Southdown wethers; Mr. Charles Large, of Burwell, Oxon, fat Oxfordshire long-woolled ewe.

PIGS.

Rev. D. Gwilt, of Ickington, Suffolk, 3 pigs; two of them 21 weeks, and one 40 weeks old, bred by himself; Mr. T. Webb, of Hildersham, Cambs., sow pig, 22 weeks old, bred by Mr. W. Webb, of West Wickham, Cambs.; Rev. A. Peyton, of Doddington, Cambs., 4 sow pigs, 9 months old, bred by himself; Rev. A. Peyton, of ditto, a sow pig; Rev. A. Peyton, of ditto, fat pig, eighteen months old.

SEED WHEAT.

Mr. G. Kimberley, of Trotworth; Mr. B. Wilton, and Mr. Samuel Jonas, the judges appointed to examine and decide on the respective merits of the White Wheat shown for the premium of 50 sovereigns, as also the Red Wheat shown for the premium of fifty sovereigns, selected for trial, according to the Society's conditions, Colonel Le Couteur's Bell Vue Talavera, grown by himself, at Belle Vue, Jersey; and Mr. John Ellis's Drewitt's improved Chidham Wheat, grown at his farm, at Send, in Surrey, as the best samples of White Wheat.

THE SHOW YARD,

was opened to the public at 7 o'clock on Wednesday morning, at which hour a great number of persons were anxiously waiting for admission. Of the cattle we have already given a complete list. The exhibition of implements was large and interesting.

MESSRS. RANSOME'S EXHIBITION.

The ploughs, though various in their forms and the purposes for which they are intended, were not

dissimilar in the principle on which they are constructed; for in all, the object of the makers appears to have been to effect such an arrangement as should best combine strength with lightness, together with such an adaptation of the several parts, as to render them effective in work, easy of management, and economical in use; to this may be added the great convenience which will be found from the parts being all so fitted to each other, that when they require to be replaced, either from wear, or accident, no time need be lost, as each new part will exactly fit and take the place of the old one, and may be exchanged without difficulty by the ploughman himself.

To most of the ploughs there was a considerable variety of mould-boards; for however well any one shape may suit a particular soil, or produce a certain description of furrow, yet the nature of soils is so various, the depth of ploughing and the mode of laying the furrows so different, that no one mould-board will suit all circumstances. To meet this, the frames, and bearing parts of these ploughs were so constructed, and the couplings which attach the mould-boards to them so contrived, as to admit of the several shapes being applied, from the simplest wedge-like form to those with the most convex or concave surfaces.

Although in the formation of ploughs for different localities science has not always held her proper place, it must nevertheless be admitted, that under great varieties of soil, difference of seasons, the condition of the land, and depth of ploughing, practical experience, and attentive observation, have done much towards the furtherance of the object desired; and it is to the hints of farmers themselves, and gentlemen interested in agricultural pursuits, that Messrs. Ransome must feel in a great measure indebted for the celebrity which their ploughs have obtained, and which has been kept up by unremitting attention.

LISTS OF PLOUGHS AS NUMBERED ON THE STAND.

—1. Suffolk swing plough, with the improved coulter and fastening. The difficulty usually attendant on setting the coulter with wedges, is by this plan completely obviated. The coulter may be raised or lowered, set to land, or from land, placed more or less slanting, or in any other direction by a very simple contrivance, as shown on the plough. 2. Belgium plough.—The mould-board of this plough is formed upon a mathematical principal, suggested by W. L. Rham, Rector of Winfield, Berks. 3. Double furrow plough.—This is made after the plough invented by Lord Somerville, for turning two furrows at one and the same time. 4. Double furrow plough, of a lighter description than the last-mentioned, and made at the suggestion of P. Pusey, Esq. 5. Northumberland ridge plough. 6. Double tom, or moulding plough. 7. West India plough, for forming trenches for planting canes. 8. West India plough, for ditto. 9. West India banking plough. 10. West India beading plough. 11. Bean drill plough. 12. Bedfordshire wheel plough. 13. Oxfordshire plough. 14. Rutland plough, made at the suggestion of R. W. Baker, Esq., of Cottesmore. 15. Plough with wheels, with frame made close on the land side, and may be used either with or without wheels. 16. Plough with wheels, with frame open on the land side, and on a very simple construction. 17. Hertfordshire plough, with wheels used on a stony soil. 18. Plough with wheels, similar to one at No. 15, but differing in the wheel fittings. 19. Plough, same as at No. 16, but with the improved coulter and fastening. 20. Scotch plough, with cast mould-board, patent case-hardened

share and wheels. 21. Rutland plough, with improved coulter and fastenings, and lever to the land wheel. 22. Plough, marked F.F. with wheels. 23. Hertfordshire and Hampshire swing plough. 24. Surrey plough. 25. Swing plough, double handles, for general use. 26. Ditto, ditto. 27. Lincolnshire swing plough.—This was made for a gentleman (B. Millington) of Sleaford, for the purpose of introducing the improved iron-work, and the patent case-hardened metal shares on the ploughs, commonly used in Lincolnshire. 28. Lincolnshire swing plough, an improvement made on the one at No. 27., under the direction of the same gentleman. 29. Lincolnshire swing plough, similar to the one at No. 28, but rather heavier and stronger. [The Lincolnshire ploughs, described as above, at Nos. 27, 28, and 29, were made with Ransomes' irons, by Anthony White, of Sleaford.] 30. Swing plough, of simple construction. 31. Swing plough (F.F.) ditto. 32. Swing plough ditto. 33. Swing plough, Lord Western's mould-board. 34. Kent turn-rest plough. 35. Ditto. 36. Ditto. 37. Hertfordshire and Hampshire plough. 38. Ditto. 39. Essex wheel plough, complete. 40. Ditto, ditto. 41. Suffolk wheel plough, with gallowaes, wheels and coulter, and set of whippetrees, complete. 42. Essex wheel plough, with gallowaes, wheels and coulter, complete. 43. Norfolk wheel plough, with gallowaes, wheels and coulter complete. 44. Norfolk wheel plough, as No. 43, but of a lighter description. 45. Rackheath subsoil plough, Sir Edward Stracey's No. 1. 46. ditto stronger, ditto, No. 2. 47. Ditto, with riser iron, ditto, No. 2. 48. Ditto, subterranean plough, ditto. 49. Norfolk subsoil plough. 50. Suffolk skim plough. 51. Mole plough. 52. Skim plough, for subsoiling and cleaning. 53. Potatoe plough, for earthing up potatoes. 54. Norfolk turnip plough. 55. Ilce plough. 56. Suffolk swing plough, light, F.F. 57. Essex ditto. 58. Swing plough. 59. Swing plough. 60. Scotch plough. 61. Swing plough, close land-side. 62. Ditto, ditto, very light. 63. Suffolk swing plough. 64. Essex swing plough. 65. Norfolk wheel plough, without gallowaes. 66. Suffolk wheel plough, ditto. 67. Surrey plough, with one wheel. 68. Ditto, ditto. 69. Bedfordshire plough, ditto. 70. Swing plough, ditto. 71. One horse plough, ditto. 72. Swing plough, ditto. 73. Hertfordshire plough, ditto. 74. Ditto, ditto. 75. Oxfordshire plough, ditto. 76. Swing plough and lever to wheel. 77. Swing plough. 78. Universal ridge plough, shown in the form as when used as a double tom, or ridge plough. 79. Ditto, when used as a moulding-plough. 80. Ditto, when used as a horse-boe, or cleaning-plough. 81. Ditto, when used as a skeleton, or broad-share plough. The universal ridge plough is adapted to the several purposes of ridge-culture, and one plough admits of all the variations as described in 78, 79, 80, and 81. The silver medal of the Royal Agricultural Society of England, was awarded to John Clarke of Long Sutton Marsh, under whose direction the Universal Ridge Plough was made by J. R. and A. Ransome—[A very ingeniously contrived implement, which will be remembered as having had the silver medal awarded to the inventor at the last meeting at Oxford.] 82. Fen plough, new, and likely to be an acquisition to the fen farmers. 83. Swing plough. 84. Kent turn-rest plough. 85. Apparatus for subsoiling, which may be attached to common ploughs. 86. Skim coulters, for turning-in surface grass.

The ploughs at numbers 12, 14, 27 and 28 were from the same patterns as those referred to in the prize essay on ploughs, by H. Handley, Esq., and

numbers, 14, 22, and 31, were those of J. R. and A. R.'s make, referred to in the experiments made by P. Pusey, Esq., to whom they are indebted for the apparatus at 8-4, for subsoiling light lands at the same time that the plough is turning a common furrow, and which may be attached to any of the several varieties of ploughs, made by J. R. and A. Ransome.

Specimens of the case-hardened metal were shown in baskets near the ploughs.

The application of metal so hardened was first introduced into the manufacture of plough-shares, by the late R. Ransome, who obtained a patent for the same, and which formed almost a new era in the use of cast iron for this purpose.

Till this mode of hardening plough-shares was discovered, those of cast-iron were little used, and were very generally condemned from their wearing thick and with a bevel, which allowed of their passing over weeds instead of cutting through them. Since this improved mode of hardening plough-shares has been introduced, and where proper attention is paid to the quality of the iron, and the management of the process of thus tempering it, this complaint has been so far removed, that in those counties where their advantages are best known, they have almost entirely superseded wrought shares.

The use of the Patent Shares do not appear to be confined to the ploughs made by J. R. and A. R., they are equally adapted to, and are also much used on those made by others.

The Turn-rest ploughs, exhibited now of different forms and weight, but on these, J. R. and A. R. are engaged in conjunction with some of the agriculturists of Kent, in making a series of experiments, with a view to some improvements on these implements, as respects construction and lightness of draught.

The plough at No. 83, was one made from the pattern furnished to J. R. and A. R. by Wm. Smart, of Rainham.

A turn-rest plough, for two horses draught, is also now preparing.

In the number of ploughs which appear in the list as exhibited at the Royal Agricultural Society, at Cambridge, by J. R. and A. Ransome, they have had in view, as a subject of general interest to Agriculturists, to show some of the variations to which the plough in one manufactory alone has been carried, and it would not have been difficult greatly to have increased the number of these variations, had they gone into those changes they are constantly adding to. Suffice it to say, that a general assortment was shown, in which ploughs more or less differ from each other either in their construction, frame-work, or fittings.

MACHINES, &c.—In giving an account of the implements and machines exhibited at the Cambridge meeting, J. R. and A. Ransome appear to have paid much attention to the improvement of machines in common use. It is with pleasure we observe the growing assent to the proposition which experience has established—that good machinery, although somewhat more costly in the first instance, is the most economical in use.

Portable Thrashing Machine, to be worked by the power of four horses.—This machine is in a form familiar to agriculturists, and little need be said in explanation of its construction. J. R. and A. Ransome have paid great attention to the introduction of good workmanship, so as to combine durability with effective performance: to this end the large iron horse-wheel is turned true in a lathe at that

part upon which the friction wheel runs; and the requisite speed of the drum is obtained by three pairs of wheels instead of two only, as was formerly the case, but which was found to involve great loss of power and wear of the machinery. Considerable saving of power is also made by the use of a new form of tooth in the wheels which combines increased strength with decreased friction, and consequently greater durability: for which improvement the public are indebted to the mathematical investigations of two Cambridge Professors—Airy and Willis.

It is difficult to give correct ideas of the quantity of work that any agricultural machine will perform, from the varying circumstances attending the operation, and so much depending upon the skill of workmen. At the trial on the 14th, upwards of 60 bushels were thrashed in one hour, and it was interesting to observe, that this machine was fed (as may be supposed in dexterous style) by a young farmer and friend of the makers, from the neighbourhood of Ipswich.

The whole of this machine is carried on two wheels, and is particularly adapted to letting for hire, as it is a moderate load for two horses, and easily put down to work and removed afterwards.

Portable Thrashing Machine, to be worked by the power of two horses.—This machine is upon the same construction as the one described for four horses, but of smaller size.

Hand Thrashing Machine.—Intended for the power of four to six men, according as it is fed. The arrangement of the parts of this machine, and the mode of obtaining the required speed of the drum are novel, and calculated for the economical use of hand labour. This knocked out five bushels in fifteen minutes in nice order.

Ransome's Patent Chaff Engine.—This machine is upon a plan, for which J. R. and A. R.'s partner, Charles May, has just obtained a patent: it is intended to be worked by one or two horses. The motion is smooth, and the length of cut can be readily altered, there are three lengths of cut $\frac{1}{2}$ in. $\frac{3}{4}$ in. and $1\frac{1}{2}$ in. upon the machine shown, but any length of cut from $1\frac{1}{16}$ th of an inch to two inches may be had, by giving directions to the makers for that purpose.

It is particularly adapted for exportation, and for cutting cane tops on sugar plantations, as the working parts are entirely of metal, and cannot be affected by the heat of climate.

The power of cutting very fine is important, as it forms part of a novel plan of preparing gorse, and which would have been shown at this meeting, but from the patent not being secured until the 6th inst. J. R. and A. R. were able to complete the machine for sale.

A set of horse-work or driving power for one or two horses adapted to the above new patent engine. No. 14.—A small machine cutting one length only, and suited to gentlemen's stables. No. 13.—The same in size and principle as No. 14, but made entirely of metal, and adapted for hot climates. No. 8.—A large machine, like the above figure, cutting three lengths, which can be varied at pleasure, and suitable for establishments in keeping ten to fifteen horses or cows. No. 6.—The same in construction as No. 8, but larger, and can be worked either by manual or horse power. A set of horse-work or driving power for one or two horses, adapted to the No. 6 engine.

Biddell's Scarifier.—This is a very powerful implement for the purpose of cultivating land under a variety of circumstances, and bringing it into a

proper state of tilth, much more effectually and at less expense than can be done by the means generally employed for that purpose.

Biddell's Extirpating Harrow.—This is particularly adapted for cleaning pea and bean stubbles, breaking up such land as is too hard for the heaviest common harrows, and for bringing winter fallows into a fine state for receiving spring corn; it is also eminently calculated in working summer lands, for raising short grass to the surface, as well as for general purposes of fine tillage, and cleaning land. The tines of this implement in their work are only four inches apart, and as steel hoes of that breadth are made to fit the tines, close shallow hoeing may be well performed. The weight of this implement, at first sight, may appear an objection, but which, on trial, will be found to be advantageous. The weight is borne upon wheels upwards of four feet high, and consequently there is not that labour to the horses in drawing it that would otherwise be the case. A set of four-horse whippletrees, suited for Biddell's scarifiers and extirpating harrows. A set of three-horse ditto. A set of Suffolk harrows, best iron and workmanship. A set of ditto, ditto.

Portable Sheep Fold.—In the construction of the hurdles, which form this fold, strength and lightness have been studied. There was only one pair of wheels to each hurdle, and the whole may be moved with great facility by either a man or a lad. They may be instantly connected with each other, and when together form a strong fold. As a temporary division on gentlemen's grounds, these hurdles would not be unsightly. By the use of hurdles on wheels, the exceedingly injurious effect of setting common hurdles with stakes over land-drains is avoided. Sheep-racks of wire, with mangers under them, are made to correspond with these hurdles, and form part of a fold or division of a field. The food, whether it be cut turnips or mown vegetable crops, being put in one side, while the sheep feed on the other. The facility of moving these folds upon hard clover land, affords the opportunity of mowing clover and other artificial young grasses for sheep—thus carrying the system of soiling to flocks as well as to herds.

A new assortment of long hurdles for a fold, with sheep racks and troughs.—This attracted a great deal of attention.

Grass Mowing Machine.—This is for cutting grass on lawns, pleasure grounds, and bowling greens, and is so easy to manage, that persons unpractised in the art of mowing, may in a short time use it with ease.

Corn stack pillar; horse drag rake; sack barrows—four sizes; steam presser; bean mill, with a set of extra rollers for malt; Norfolk crusher, for breaking malt; Suffolk ditto, ditto; oil cake breakers—two sorts; barrow turnip cutter; Finlayson's patent harrow; Gardner's patent turnip cutter; ditto on wheels; Salter's patent winnowing machine—the Patentees were present showing this machine.

Hay Bay Beater.—This machine is for the purpose of taking the dust out of mouldy hay, previous to use or being cut into chaff.

MESSRS. GARRETT'S EXHIBITION.

R. Garrett and Son, Leiston Works, Saxmundham, Suffolk, had a most remarkable display of implements, proving their great ingenuity and skill in the production of the most useful machines for the purpose of agriculture, viz.—Seven different varieties of drilling machines, two thrashing machines varying in principle, varieties of chaff-cutting en-

gines, dressing machines, winnowing machines, cake crushers, ploughs, bean mills, and a hay making machine; also an improved horse power for cutting chaff, grinding corn, &c., with the means of instantly stopping the progress of the work without checking the movement of the horse. The proportions, application, quality of workmanship, and materials in these implements were truly gratifying, and received the commendation of the most distinguished noblemen and eminent agriculturists present. R. G. and Son also exhibited admirable models, the work of much time and ability, of a corn, seed, and manure drilling machine, perfectly proportioned to the sixty-fourth part of the full cube size, shewing all the most recent improvements, viz.—Swing steerage, screw regulator, and press bars. This drill, with all the apparatus as shown, is the most complicated at present manufactured, and will deposit with accuracy corn and manure, or seed and manure, through the same or separate coulters. Two men are sufficient to work it. The use of the swing steerage is to guide the depositing coulters to the greatest nicety, so as to make the rows of corn regular in returning, and the same improvement materially assists in drilling on the tops of ridges. This machine is easily altered so as to be applicable to either broad, stretch, or ridge work.—Also of a four horse power thrashing machine made to the sixty-fourth part of the full cube size, showing likewise all the most novel improvements, viz., on whole iron wheel with segment attached, and an entire iron drum with five beaters. It is confidently asserted that this machine will thrash any kind of corn without injuring either the kernel or straw, at the rate of from thirty to fifty bushels per hour, while the horses do not walk more than two and a quarter miles per hour, the machinery being timed to the greatest nicety by three motions. This thrashing machine is the most economical in use; it may be taken up or put down (with the assistance of the lever purchase) by two men in half an hour, and it is so thoroughly adapted for removal, that when loaded on the travelling wheels, two horses can convey it from place to place. Seeds may also be drawn by the addition of another concave and grating. The following is a representation of the machine.

And of a lever corn drill made in the same proportions and in the most simple form. These are all so convenient in size for removal, and so plain and intelligible, that they cannot fail greatly to forward the adoption of such useful implements in the most remote districts.

Mr. Seatter exhibited an improved winnowing machine, for which the Royal Agricultural Society awarded a silver medal at the meeting at Oxford last year. Mr. Smith, of Peasenhall, near Yoxford, Suffolk, some very excellent drills, which attracted great attention.

One of the Marquis of Tweeddale's drain tile machines was exhibited, and great surprise was expressed by those present at the celerity with which the tiles were made.

Amongst the machines, Messrs. Bond, Turner,

and Hammond, of St. Peter's Foundry, Ipswich, exhibited some excellent drills for corn, seed, and manure; others for sowing corn and seeds at the same time, and some for corn and seeds separately. A very superior and powerful thrashing machine of four horse power; the manner it performed its work was particularly admired, and which thrashed in a superior manner twenty-four bushels of wheat in twenty minutes, being more by one-fifth, than any machine realized in the same period of time. Also, some excellent oilcake breaks adapted for sheep, beasts, and manure of various sizes, which were very highly approved, and amongst the variety of goods exhibited, and which our limits prevent our noticing separately, we might notice plough for subsoils and other purposes, new constructed iron sledges, chaff engine, dressing machines upon Cooch's principle, malt and bread mills, &c. And a premium was given by the Society for their new invented machine for crushing gorse.

Messrs. Perry, Barrett, and Exall, of Reading, Berks, brought for inspection a great variety of ploughs and other agricultural implements. The Dibbling Machine, shown by Mr. Wedlake, of Hornchurch, Essex, was surrounded by crowds during the meeting, who expressed themselves highly pleased with its ingenious construction.

There was also a good assortment of implements brought by Mr. Howard, of Bedford; among which we observed his Patent Plough, which appeared to be constructed on new principles. The shifting draught is a great improvement, and the light plough was exceedingly strong.

Here follows a cut representing this plough.

Mr. Howard's Patent Harrows attracted considerable notice from their durability and the excellent manner they performed their work. We cannot speak otherwise than in the highest terms of these implements. The following is a cut of Mr. Howard's harrow:—

The portable hand-power thrashing machine, shown by Mr. B. Urry, of Newport, Isle of Wight, was decidedly one of the most excellent machines of that description we ever had the pleasure to witness. The apparent ease with which it was worked, and the large quantity of wheat threshed out in a limited period, were the theme of universal approbation. In

order to give our readers an idea of the machine, we insert the following wood-cut—

SIDE VIEW OF ABOVE CUT.

- A. refers to a cog wheel running in a small pinion
- B. Threshing cylinder.
- C. Canopy to prevent the grain flying about, which closes up when not at work.
- D. Standing board, which closes up, with joints.

Mr. W. Crosskill, of the Iron Works, Beverley, Yorkshire, sent for exhibition his celebrated Iron Clod Crusher, and it affords us the highest gratification, both from the practical knowledge of its working, and the well-grounded conviction that every farmer ought to be in possession of one, to perceive that the crowds of agriculturists who surrounded it, pronounced it one of the best machines they ever witnessed.

Mr. Cottam was present with his excellent Dynamometer.

The following were exhibited by W. Drummond and Sons, of the Agricultural Museum, Stirling, Scotland, and were admired for their utility and elegance of workmanship. Their expanding horse-hoe, reaping scythe, and grain sample weighing-machine, drew especial attention—Smith's subsoil plough—Iron swing-plough—One-horse green crop grubber, with double mould boards and scufflers to fit—Expanding one-horse-hoe, and harrow for drill culture—Diamond drill harrow—Sawing machine to cross cut logs for fuel, &c.—Portable weighing machine, weighs from 3oz. to 4 cwt.—Ayrshire cheese press—Hand-stubble rake on wheels—Improved reaping scythe—Machine for twisting three straw ropes at a time—Implements for the various kinds of drains—Cast iron stack pillar, to prevent vermin getting up—Pheasant and poultry feeder—Improved oval churn—Milk cooler, and search made of zinc—Improved ring for leading cattle—Instrument for probing hoven cattle—Cattle probang—Corn balance to give the weights of any kind of grain from a sample—Spurred shovel for filling and turning potatoes—Clips for dragging out land-fast stones—Improved latch for a park gate.

The following manufacturers also exhibited implements:—

Mr. W. W. Kilpin, of Bedford, turnip machine; Mr. W. Young, of Yarlington, horse hoe; Mr. J. Clark, of Long Sutton, turnip cutter; Mr. S. King, of Buckland Farringdon, plough; Messrs. White and Leith, of Worksop, mill for bruising gorse, &c.; Mr. W. Grounseil, of Louth, a drop drill scarifier, &c.; Mr. J. Woods, of Stowmarket, a considerable variety of agricultural implements; Mr. Maynard, of Whitlesford, Cambs., various drills, weighing machines, dressing ditto, spreading ditto, &c.; Mr. Balls Garrett, hand-threshing machines, chaff engines, winnowing machines, model steam apparatus, ploughs, &c.; Messrs. Barrett and Exall, of Reading, various ploughs, winnowing machines, chaff engines, mills, rollers, &c.; Mr. Smith, of Peasenhall, a drill, called Lord Western's drill; Mr. W. F. Hobbs, of Mark's Hall, Essex, a fold sheep trough, and a fold hurdle; Messrs. R. Headley and Sons, various implements; Mr. A. Hayward, of Grinstead Green, Essex, subsoil ploughs, and scarifier; Mr. R. Horn-

aley, of Grantham, portable horse powered threshing machine.—Mr. R. Hornsby, of Spittlegate, a patent drop drill; Mr. H. W. Wilson, machine for scaling turf for burning; Mr. T. F. Salter, of Great Hallingbury Hall, patent winnowing machine; Mr. J. Smyth, of Peasenharn, various kinds of drills; Mr. T. Wedlake, of Horncchurch Foundry, haymaking machine, dibbling machine, chaff engines, turnip drills, ploughs, &c.; Mr. W. Block, of Peasenharn, drills, &c.; Messrs. T. Gibbs and Co., Seedsmen, &c., of the Corner of Half-Moon Street, Piccadilly, London, a Belgium carrot hoe; Mr. T. Hinkvale, of Over Norton, ploughs of various kinds; Messrs. Bond, Turner, and Harwood, of Ipswich, drills of various kinds, threshing machines, dressing ditto, ploughs, mills, rollers, carts, &c.; Mr. J. Wick, of Hadleigh, model of dipping apparatus, also a washing ditto; Messrs. Smyth and Son, of Smifling, Suffolk, various drills; Mr. Constable, a machine for drawing trefoil and clover.—This machine has been submitted to several of the most opulent farmers in Cambridgeshire, and has been found to answer the purpose better than any hitherto invented, as it does not injure either the seed or the chaff, and will draw from 48 to 60 bushels of trefoil seed per day, and upwards of 30 bushels of clover seed. As the Society had offered a prize for a machine for bruising gorse or furze, for feeding cattle, the following description of the one exhibited by Mr. Dell, of Dudswell, may be found interesting:—This machine is composed principally of cast iron, with a circular platform, the inner and outer side of which is raised, the bottom of the circle is grooved after the manner of a millstone. The outer raised edge is cogged or toothed like a rack, in this circle or trough is an iron roller, through which a shaft is introduced and connected with a pin in the centre of the machine; to the other end of the shaft a poney or ass is to be attached, as in other mills worked by horse power. The particular improvement, however, in this machine, and which enables it to perform much more work than any other bruising machine now in use, is the addition of a pinion, cogged in the same manner as the outer edge of the trough above-mentioned, and attached to the outer end of the roller. The addition of this pinion, working in the rack above-mentioned, causes the roller to revolve nearly as many more times in going round the trough, as it could otherwise do, were the rack and pinion absent, which gives it a very effective grinding motion, by which a roller of four cwt. will perform considerably more work than one of a ton weight, working by simple pressure only. The implements of one of the most new and useful invention exhibited was, in our opinion, a machine for the manufacture of draining tiles, for which a patent has been obtained by Mr. R. Beart, of Godmanchester. This very useful machine, which is sold complete for 12 guineas, must prove most valuable to the large farmer, as it will enable him to provide his own tiles, in a superior manner, and at a considerably decreased expense. It is extremely simple; much more so, in fact, than the well-known machine of the Marquis of Tweeddale. We also recommend to the notice of those who use Bigg's sheep-dipping composition, a newly constructed dipping-tub; it combines two very valuable desiderata—the prevention of many accidents which occur in this necessary operation, and also a considerable saving of the liquor employed.

We were much gratified by the exhibition of roots, seeds, &c., among which we could not help viewing with particular satisfaction the stand of Messrs. Thomas Gibbs, and Co., Seedsmen, of the

corner of Half-moon street, Piccadilly, London, whose celebrity in the agricultural world made us anticipate a splendid shew, and every individual who visited the shew-yard must acknowledge that that anticipation was fully realized, and thus the farmers of this country had an opportunity of inspecting samples of articles in which they must take the greatest interest, in which they are particularly concerned, and the importance of which must be felt by every one engaged in agricultural pursuits. Among other articles of general attraction on the stall of Messrs. Thomas Gibbs, and Co., were samples of grass seeds for laying down land to permanent pasture, dried specimens of the same in their mature state, exceedingly large roots of mangelwurzel of the growth of 1839, a Belgium carrot, and a large collection of agricultural seeds. We also observed on the stand of Messrs. Thomas Gibbs, and Co., specimens of wheat exhibited by Colonel Le Couteur, so well known by every one taking an interest in the different varieties of wheat.

At the sale held in the yard on the following day, conducted by Mr. Wetherell of Durham, expressly engaged by the society for that purpose, a great number of all classes of stock were sold, and at high prices. This mode of sale cannot fail to be of the greatest acquisition both to buyer and seller, where gentlemen from all parts of the kingdom attend, and who can purchase stock from the most eminent breeders, of the different descriptions to best suit the climate and soil on which he lives.

Referring to the exhibition in the Cattle yard, we may observe, that as a whole, it was superior to that of last year. Nevertheless, without being hypercritical we think that some of the classes of animals were open to remark, as well as the awards on them. We certainly speak under correction, but we do think that one of the decisions, in the first class, is not free from doubt.

In speaking of the merits of the animals in this class, we cannot omit to notice the general admiration of the splendid yearling Bull, Clementi, belonging to R. M. Jacques, Esq., of St. Trinians, near Richmond, Yorkshire, which obtained the first prize in his class, beating ten others. Mr. Jacques has a superior herd of the improved Short-horns, and has been a successful exhibitor of Clementi, at the Richmond and Barnard Castle Agricultural Shows. He also obtained the premium of Ten Sovereigns at this meeting, for the best short-horned yearling heifer. Clementi was bred by Mr. Parkinson, of Lee Fields, near Ollerton, Nottingham, got by Cossack, (1880 in the herd book, dam Cassandra, by Miracle), and was bought by Mr. Jacques in Sept. 1839, for 300 guineas; Collard, which is own brother to Clementi, was bought by Mr. Wetherell at the Babworth sale, in May last, then 8 months old, at 200 guineas, for R. M. Fox, Esq., of Fox Hall, near Rathowen, Ireland. Mr. Parkinson has an extensive and select herd of the improved short-horns, for several of which, premiums have been awarded at the Nottingham, Lincoln, and Ollerton Agricultural Shows.

The second class Herefords do not come up to our estimate of the same class at Oxford. The cow belonging to Sir H. Hoskins, in this class, was a beautiful animal.

The same remark applies to the third class Devons. The award of the Judges in this class excited much observation: we do not pretend to offer an opinion on the merits of the different beasts, but we venture to suggest that in future it would be a means of avoiding dissatisfaction if one of the three Judges in each class should be a breeder of, or have had his attention more especially directed to the particular breed in that class.

The fourth class, for all breeds, was decidedly worse than last year.

The fifth class, Horses, was very superior to last year; especially the cart-horses, which were very good.

The sixth class, Leicesters, were good. Mr. Bennett's shearing ram was greatly admired.

The seventh class, Southdown Sheep, was so excellent as to scarcely admit the expectation of our seeing it better.

The eighth class was also good, and Mr. Large was deservedly successful.

The ninth class, Pigs, attracted considerable attention, especially Lord Western's, Mr. Hobbs's, and Mr. Barnard's.

We embrace this opportunity to correct an error in one of our contemporaries, who stated that a Bull belonging to Earl Spencer was greatly admired. Earl Spencer purposely avoided exhibiting, having accepted the office of Steward of the Yard. The mistake arose no doubt from the animal being described as one of his Lordship's breed.

We should not omit to mention that Mr. Pratt, of Spelsbury, Oxfordshire, having challenged all England to show five wether sheep, fifteen months old, for 50*l.*, the challenge was accepted by Mr. White, of East Hall, Kent, for 20*l.*, and was decided on Wednesday in favour of Mr. Pratt. The judges were Mr. Stunt, of Higham, near Rochester, and Mr. Carpenter, of Hall Farm, near Chipping Norton.

The price of admission from the opening of the yard at seven o'clock on Wednesday morning until twelve was 2*s.* 6*d.* each person, and after that period until seven in the evening, 1*s.* each; the sum received during that time was 1,480*l.*; and on the following morning about 140*l.*, making on the whole, 1,620*l.*; being about 450*l.* more than was received at Oxford.

PORTABLE SHEEP-FOLD.—An improved portable sheep fold, in which one of the hurdles also serves the purpose of a trough or rack, was exhibited by Mr. W. F. Hobbs, and sold.

MR. JONAS WEBB'S TUP SHOW.

At the conclusion of the ploughing match, on Tuesday, a very great portion of the spectators visited Mr. Webb's farm, at Babraham, among them his Grace the Duke of Richmond. The noble Duke expressed the great pleasure he felt in inspecting Mr. Webb's flock, and regretted that his duties at Cambridge prevented him from being present at the letting. Previous to and during the letting Mr. Webb kept open house. About half-past two the letting commenced, and was carried on with very great spirit, many of the tups fetching high prices. In the course of the afternoon the Earl of Hardwicke arrived, accompanied by the distinguished guests visiting at Wimpole. Among them we observed the Duke of Rutland, the Marquis of Salisbury, Lord Ashburton, the Marquis of Downshire, Lord Barrington, Lord Charles Manners, the Hon. E. T. Yorke, Sir G. Seymour, Rt. Hon. T. Croker, Mr. Denison, M.P., and Mr. Vincent, who appeared highly gratified with their visit. Having remained about half an hour, they departed from the place of letting and proceeded to Mr. Webb's house to partake of some refreshments, and pay their respects to Mrs. Webb, whose excellent arrangements in providing for her guests, and the courtesy evinced by her towards all, was the theme of universal commendation.

About 200 tups were disposed of, which was nearly the whole number offered, and among the most distinguished hirers of them we heard the

names of the Duke of Manchester and the Earl of Hardwicke mentioned. The Duke of Richmond, we understand, offered Mr. Webb 100 guineas for a ram lamb, which the latter refused.

THE DINNER.

At six o'clock, the letting having concluded, a party consisting of between three and four hundred sat down to a cold dinner, the Hon. ELLIOT YORKE, M.P., in the chair. The collation was prepared in a spacious barn, with an additional marquee, beautifully decorated with evergreens and flowers, exhibiting much taste and ingenuity. The excellence of the dinner was the theme of universal praise, and although so large a number sat down, and many hundred others had been regaled in Mr. Webb's house during the day, yet the provision was ample.

The Hon. CHAIRMAN first proposed "The Queen," and said there was no gentleman present who would not join him in cordially drinking that toast, and all he was sure felt thankful to Providence for averting that blow recently levelled at her Majesty, whose life was dear to them all (*the toast was given with loud cheers*).

The CHAIRMAN next gave His Royal Highness Prince Albert, and then the Queen Dowager and the rest of the Royal Family. After that followed the health of the Lord Lieutenant of the county. (*Loud cheers.*)

E. HICKS, Esq. said, that the Hon. Chairman being a relative of the noble Lord Lieutenant felt a delicacy in proposing that this toast should be given with three times three. But he was sure that every one now present would be happy to join in that cheer, for there was no man more esteemed in the county to which he had the honour to belong (*the toast was received with great cheering*).

The CHAIRMAN said he hoped that in drinking the next toast they would charge their glasses to the brim, for it was one that highly deserved it. It was the health of their worthy host. The hospitality that they had met with that day, was beyond all precedent, and he hoped that Mr. Webb would meet with the reward he so richly merited. His occupation was alike honourable and ancient. They had read that Abel was a keeper of sheep, the sons of Meschid, in the land of Moab, were shepherds and keepers of sheep. It was an honest and useful occupation, and in discharging the various duties connected with it, Mr. Webb was exemplary. He was entitled to their highest praise for the benefits he had conferred upon the breeders of sheep in general, and he had no doubt his example would be the means of stimulating others to follow in the same track. He would give the health of Mr. Jonas Webb with three times three. (*Loud and continued cheering.*)

Mr. JONAS WEBB, who acted as Vice-president, returned thanks. He said he was afraid it would be considered a poor compliment when he said he had not been paying attention to the observations of the hon. Chairman. He was much gratified to find so many friends around him—many from a great distance—and many who were customers as well as friends. He thanked them most sincerely both for their attendance and their custom, and hoped he should have the pleasure of seeing them another year. (*Cheers.*)

The CHAIRMAN said that being within hearing of Mr. Adeane's house, he thought they could not do better than drink his health. He was quite sure the company would heartily respond to it. He regretted Mr. A. was not present upon that occasion, as that

gentleman was always ready to do justice [to Mr. Webb as a good tenant and an enterprising man, and he thought Mr. Webb would bear testimony with him (Mr. Yorke) in saying that, as a landlord no better existed. He would therefore give the health of Mr. Adeane.]

The CHAIRMAN said, the next toast was the health of the noble Duke, the chairman of the Royal Agricultural Society of England. (*Cheers.*) His grace was a sterling friend of agriculture, and as hard a working man as any he then saw before him. (*Cheers.*) He sincerely wished that the noble duke, instead of having offered the one hundred guineas for Mr. Jonas Webb's best lamb had been fortunate enough to pay it. (*Three times three, and loud cheers.*)

The Rev. Mr. Cox proposed the next toast. He could have wished it had fallen into other hands, but being requested, it would ill become him to refuse, after partaking of the kind hospitality of Mr. Webb, and witnessing his excellent stock. The toast he was about to propose was "Success to Agriculture," which he considered to be the great stay and bulwark of this nation. (*Cheers.*) He came from Essex, than which no county was better cultivated. They had derived great benefit from the cultivation of seed; next in point of importance, was the growth of wool. But as farmers, they might depend on it that nothing could benefit them and this country so much as the growing of large quantities of corn. (*Cheers.*) Farming, was now, he was rejoiced to say, in a flourishing state; but their mainstay was in producing large quantities of wheat by improved cultivation—an object societies like that now assembled at Cambridge, was so well calculated to effect. The toast was then received by acclamation.

The CHAIRMAN then proposed, with much humour, "Mr. Perkins (of the celebrated firm of Barclay and Perkins,) and the Brewers of the metropolis." (*Cheers.*)

Mr. PERKINS returned thanks. He little thought he was to receive such a compliment; it had come upon him quite unawares, and therefore he trusted they would excuse him if he did not return thanks so elaborately as he could wish. But the benefit between them was mutual—for if the farmer did not grow the barley, the brewer could not use it. The brewer could do nothing without the farmer, and he hoped that the farmer would be able to produce a good barley, and the brewer would produce a wholesome beverage. He made it his business to travel through the country every year, and he regretted that in coming here he had not witnessed such good barley crops as he could wish. But still he had witnessed quite enough to convince him, that the gentlemen who surrounded him were good farmers. (*Cheers.*) He heartily thanked the honourable chairman, the worthy host, and the company around him, for the honour they had done him.

Mr. HICKS proposed the Bishop and Clergy of the Diocese, which was given with cheers.

The CHAIRMAN then gave the health of Mr. Putland, and the gentlemen who had come from a distance.

Mr. PUTLAND, (of Firle, near Lewes) spoke to the toast. He derived great gratification from the toast they had just heard, and the way in which it was received, in a double point of view—first for the handsome way in which his name had been mentioned, and next for the honourable mention of the growers of the county of Sussex. It would be of very little use, however, for them to grow South-downs, if they did not meet with encouragement from their customers in Suffolk, Essex, and Cam-

bridgeshire, and he hoped he should convince his friends when he had the pleasure of seeing them at Lewes fair, that he met them as fairly, as honourably, and he trusted as hospitably as they had been that day treated. (*Cheers.*)

Mr. JONAS WEBB then gave the health of their Chairman, the Hon. E. T. Yorke, and he thanked him for his kindness and condescension in taking the chair on that occasion—*three times three.*

The CHAIRMAN, in returning thanks, said it was peculiarly gratifying to him to witness the enthusiastic manner in which his health had been received by the company present, consisting as it did of a great number amongst them who were strangers both to him and the county. He considered it no condescension on his part to take the chair upon that occasion, but, on the contrary, he begged most distinctly and emphatically to state that it was from inclination that he had done so. He would conclude in the words of a celebrated poet—

"I am a beggar, for I am poor in thanks;
But from my heart I thank you."

Mr. BAWSHEN then proposed the health of Mr. Taylor, brewer and malster, of Saffron Walden, a gentleman extensively connected with agriculture in this as well as the adjoining counties.

Mr. TAYLOR said if they expected a long speech from him they would be disappointed. It was true he was intimately connected with the malting interest of this and the neighbouring counties, and if they would but produce a good quality, his honourable friend on his right, (Mr. Perkin,) would take it all from them. He was happy to say that beer-drinking increased, and he was sure it would soon, but at present they did not grow anything like enough of barley, and if they would but grow good barley and plenty of it, there would be no fear of their obtaining remunerating prices. (*Cheers.*) He had been invited to meet them here at this period, but why he knew not, for he knew nothing about sheep, although he highly esteemed his friend, Mr. Webb. He sincerely thanked the company. (*Cheers.*)

Mr. Putland then gave "Mrs. Webb, and the Ladies of Cambridgeshire."

Mr. J. WEBB returned thanks.

The CHAIRMAN then proposed the health of Mr. Webb, sen., and congratulated him upon having a son so worthy of his sire.

Mr. WEBB approached the table amidst the loudest and most enthusiastic cheering, then in few, but emphatic words, very feelingly returned thanks.

Mr. JONAS WEBB proposed the health of Mr. Purvis, agent to the Duke of Manchester.

Mr. PURVIS trusted he should be pardoned for the inadequate way in which he should return thanks for so unexpected an honour. He came to this show not so much to benefit Mr. Webb as to benefit his noble employer, and he should be gratified if they had so enterprising a man as his friend, Mr. Webb, in the little county of Huntingdon, to which he belonged; they should not then, he trusted, be so far behind in agriculture as they now were. At all events he endeavoured to do his duty by taking into that county some of Mr. Webb's excellent South-down sheep (*Cheers.*)

The CHAIRMAN, in proposing the next toast, said, he wished he had half the voice, and possessed half the importance of the great man whom he was about to introduce to them. He had himself in the course of the evening been taken for Mr. Elliot Smith; he could almost wish that half the body of that gentleman were transferred to him, in order to make up

for his own deficiency, and diminish the superabundance of that well-known and highly respected individual. The Chairman concluded by proposing the health of Mr. Elliot Smith, and may he long live and continue in the same useful and honourable profession.

Mr. PUTLAND then proposed the health of his friend, Mr. Teverson.

Mr. TEVERSON returned thanks, and spoke very highly of the treatment he received in the county of Sussex. He hoped he should be honoured with the company of all who were here present, and their friends in September next, and he would be able, he trusted, to show them some shearing ewes to match with the splendid tups shown by their worthy host that day. (*Cheers.*)

The CHAIRMAN then left the chair, which was taken by Mr. Webb's brother, and many gentlemen gathered round him to prolong the festivities of the evening.

THE CORN LAWS.

TO J. W. CHILDERS, ESQ., M.P.

SIR,—You have lately published a tract entitled "Remarks on the corn laws," in which you strongly urge the necessity of their repeal. As these "Remarks" are addressed to the public, I apprehend they are open to public criticism; and therefore make no apology for addressing this letter to you in reply to the opinions therein expressed.

Your "Remarks" do not seem to contain anything in the shape of argument, but are made up chiefly of a reiteration of the assertions and common places, which have been so industriously set forth by the indefatigable gentlemen of the anti-corn law league.

You say, (page 5) "I think the effects of the corn laws are very much exaggerated by both parties. I think they do not, in the long run, make corn much dearer; and I venture to prophecy, that whenever they are done away with, the change will be comparatively slight, and that rents and prices will continue *in statu quo* much more than could at first be imagined." Also, in page 6, "I imagine, therefore, that the diminution in the price of corn to the agriculturist will hardly be perceptible. It is also my opinion that corn never can be had very cheap in England."

If these surmises be well grounded, it is folly on the part of the agriculturists, or any other class of people, to desire a continuance of the corn laws, under the idea that they are at all benefitted by them. And it is equally foolish on the part of the anti-corn law league and the manufacturer, to give themselves such a world of trouble to procure the repeal of the corn laws, with the expectation of its causing such a reduction in the price of food, as will enable them so far to reduce wages, (or as they term it, the cost of production, that they may be enabled to compete successfully with the manufacturers on the continent. If these opinions be correct, the hopes of one party and the fears of another would be groundless. We are inclined to think, however, that the majority of the anti-corn law party regard the repeal of these laws with very different expectations.

Knowing scarcely anything more of the subject than what they have learned from the sophistries and misrepresentations of the hired advocates of repeal, it cannot be expected that they should thoroughly comprehend all the bearings of a subject which puzzles

and perplexes the most learned and talented men, both in and out of parliament. The great majority of the petitioners for repeal are the converts of sound rather than of reason, and clamour for a repeal of the corn laws, only from the delusion that the pleasing and seductive sound of *cheap bread* means bread easy of acquisition. That the money price of corn would be reduced by repeal we firmly believe: yet, at the same time, it is our strong conviction that bread, instead of being easier of acquisition, would be still more difficult for the poor to obtain. I will now endeavour to state some of the grounds on which the agriculturists may apprehend, that a repeal of the corn laws would reduce the price of corn below the remunerating point; and to controvert your assertion, that "corn never can be had very cheap in England."

[In any references we have to make to other publications, we shall endeavour to confine ourselves to those writers who are opposed to us in their views on this question, in order to avoid any accusation of giving garbled statements in favour of our own opinions.]

In the fourteenth number of the anti-corn law circular, a quotation is given from a report of the corn markets contained in the *New York Herald*, of October 1, 1839, from which we extract the following:—"Tennessee wheat is sold on the coast of the United States at 6 dollars 12½ cents per quarter, or only 3s. 3d. per bushel. "In Indiana the bushel of wheat is 2s. 8d., in Ohio 2s. 3d., in Virginia 2s. 1d., in Wisconsin and Michigan 2s. 1d., in Tennessee 1s. 6½d., and in the Western States from 10d. to 6½d., or 4s. per qr."

In the previous number of the anti-corn circular, it is said, "We learn from the most recent accounts that in Georgia abundance of the finest wheat is to be had at 2s. 6d. per bushel, or only 20s. per qr. Suppose the cost of transport to amount to only 50 per cent., then each quarter of fine Georgian wheat would be laid down at the very door of our factories at 30s. per qr."

The newspapers of the day occasionally give the average price of wheat in England, and in different parts on the Continent. We extract the following table of prices, given in "Wilson's Influences of the Corn Laws," page 11:—

Year.	Average price in Great Britain.	Average price in Dantzic.
1824	62s. 0d.	22s. 9d.
1825	66 6	23 3
1826	56 11	23 1
1827	56 9	22 5
1828	60 5	24 4
1834	46 2	25 5
1835	39 4	23 0
1836	48 6	28 7
1837	55 10	29 0

Average of the } nine years. }	54 8½	24 7½
-----------------------------------	-------	-------

We see, then, that the average price of wheat in England, during the nine years above quoted, was upwards of 30s. higher than the prices at Dantzic for the same time. These tables also shew the prices in Königsburg, Brandenburg, Pomerania, and other Prussian ports, to be even lower in these years than at Dantzic.

Now, if we had had a perfectly free trade in corn during this period, should we have had the same prices of corn in England?

On referring to the *Mark Lane Express* of last week (June 15), I find it stated in the usual article on the "Foreign Corn Trade," that, by letters from

Dantzic, of the 6th instant, "vessels were not so plentiful as they had been; and small ships commanded 4s. per qr. freight for London, and 4s. to 4s. 4d. per qr. for other parts of the eastern coast of England. Our Stettin advices are also of the 8th of June. A good many vessels had arrived there, seeking freights; at 4s. per qr. a few had been taken up for the East." We are not able to state what additional charges there may be on wheat from Dantzic or other parts of Prussia, but on making enquiries respecting the expense of conveying wheat from Hamburg to Hull, we are informed, on the very best authorities, that the present freight for wheat is 2s. 6d. per qr.; insurance, $\frac{1}{4}$ per cent., or about 3d. per qr.; landing and all other charges, 6d. per qr. On particularly enquiring if this was the total cost of importing wheat from Hamburg, our informants assured us they knew of no other charges than what we have stated above, amounting in the whole to 3s. 6d. per qr. If, however, we are stating anything that is incorrect, it will be in the best place that can be for being contradicted. A variety of exaggerated statements are circulated of the heavy costs of importation; but what will our readers think when we tell them that we have been positively assured by more than one person on whose veracity we can rely, that they have on some occasions known wheat to be imported from Hamburg at the low freight of 1s. per qr.? The only item of cost in importing corn from Dantzic, or any other Baltic port, to which corn from Hamburg is not subjected, is, we believe, the Sound dues, 6d. per qr. The following accounts will therefore, as far as we know, be nearly correct:—

	From Dantzic.	From Hamburg.
Freight.....	4s. 0d.	2s. 6d.
Insurance.....	6	4
Sound dues.....	6	none
Loading, &c.....	6	6
	<hr/> 5 6	<hr/> 3 4

We must bear in mind that the merchants seldom incur any charges for factorage, or commission. It would seem, then, that if we had an entirely free importation of corn at this moment, we could not reasonably expect the price of wheat here to be more than 3s. or 6s. per qr. above the Dantzic prices, nor more than 3s. or 4s. above the Hamburg prices. But there is another thing that we must not forget, namely, the superiority of the Dantzic and other foreign wheats over those of English growth, which will amply cover the cost of conveying it to the English markets. In Radford's "Hull Commercial Report and Price Current" the average current price of English and foreign was, for

May.	English, new....	55	66	68
	Foreign, free....	65	69	75
	Difference..	10	3	7

Which shews a difference in favour of foreign of more than the cost of conveyance to our markets. As a further proof of this we need only mention the well-attested fact, that merchants contrive to adulterate their parcels of foreign wheat, by mixing with it English wheat of the same apparent quality, thereby obtaining a foreign price for the whole. It is not that there is that difference in the respective qualities as an article of food, but the foreign, on account of some peculiarity of the climate or soil on which it has been grown, is less productive of coarse, or what the millers term, offal. If, then, we are to have a free trade in corn, and should the prices of wheat in

Dantzic be hereafter reduced to what it averaged during the nine years we have quoted above (24s. 7½d.), would any one expect that the average price of wheat in our markets would be, as in the nine years we have spoken of, 30s. per qr. above the prices at Dantzic? or could there be any reasonable grounds for expecting that it would be 30 pence above it?

With reference to freights, I would further observe, that the distance from London to the principal Scotch and Irish ports which ship corn to that place, is greater than that from the ports of Holland, Germany, and Prussia, whence the bulk of our foreign importations are derived. It is quite clear, therefore, that the Scotch and Irish (the price of whose grain is ruled by what their surplus produce will command in the English markets) could not possibly, under a free trade in corn, obtain one farthing more than the people on the coast of Holland, Germany, Prussia, the lower ports of the Baltic, and the eastern coast of France, even if their grain was equal to that of the foreigners in quality. We are informed by two of the principal corn merchants in the West of England that the freights for wheat from Lynn, Wisbech, and Boston, to Wakefield, being the three places from which the latter receives its largest supplies, is from 2s. 6d. to 3s. per qr. The district in which Manchester and many other of the large manufacturing towns are situated, being on a substrata of coal, is necessarily barren. These places are consequently obliged to procure their corn through Liverpool, Wakefield, Leeds, &c., which imposes an additional 5s. 6d. per qr. on all corn shipped to Manchester from the western ports of England. Grimsby, Louth, and even the neighbouring town of Driffield, in Yorkshire, cannot send wheat to Manchester for less than 5s. 8d. per qr., a sum which would freight corn to Hull or London from almost any port on the western coast of continental Europe. One of my informants says, "It costs fully as much to get corn from Lynn to Wakefield, as it does from Hamburg to Goole." And as the cost of conveyance from Wakefield to Manchester is to the same amount, it follows that it costs twice as much to get corn from Lynn, Boston, Wisbech, and other adjacent ports on the eastern coast, to Manchester, as it does from Hamburg to Goole. It is, perhaps, not necessary to say more in order to show that the repeal of the corn laws would ultimately bring the price of English and foreign corn to the same level in our own markets: what that level would be, is not so easy to ascertain. Foreign noblemen and capitalists have occasionally offered to contract for the supply of large quantities of foreign wheat, to be delivered in English ports, at 30s. per quarter.

After the two or three very unfavourable seasons which have caused the late advanced prices, some people may be so far misled as to suppose it quite improbable that the price of wheat can ever be reduced to 30s., thinking, with yourself, that "corn never can be had very cheap in England." The seasons, however, as experience has shown us, generally run in courses. After two or three very unproductive harvests, we may have a like number prolific to a like extreme. It is idle to talk of this country not being able, in moderately productive years, to grow a sufficiency of corn for its own consumption; for it is only four or five years ago that the abundance of our home produce was such, that the best of wheat in our neighbouring Yorkshire markets would not command more than 32s. or 34s. per quarter; and many thousands of quarters were even used for pig's feed.

However rapidly the population of the country may increase, it is quite certain that the improvements in farming have latterly more than kept pace with it; and the science of farming need not necessarily be further advanced to enable the soils of this country, in moderately favourable seasons to produce a sufficiency of food for every individual of its population. Indeed, there are few persons at all acquainted with an agricultural district, who cannot point out some particular farm which is managed in such a way that if the productive powers of every other farm in the country were called forth in a similar manner, there would be food of home produce, enough and to spare, for any increase of population that could take place for centuries yet to come.

It is an established maxim that supply and demand regulate prices; and whenever we may be favoured with two abundant harvests in succession, the supply must inevitably exceed the demand, and the prices be depressed accordingly. I shall not be contradicted when I say, that the produce of the crops have, in different years, sometimes varied fully one-third, when the bulk has been perfectly equal in point of appearance. Tooke, in his work on "High and low prices," very properly notices the extraordinary deficiencies caused by "wetness in May, cold frosty nights in June, from boisterous winds when the plant is under the blossom process, and from want of sun, and heat, when the grain is formed in the ear of the plant," and the contrary weather which, of course, produces an opposite result. The general similarity of the seasons throughout the corn growing countries of Europe is thus noticed by the same author. "Mr. Lowe, in his very useful and valuable work on the present state of England, has the following remarks, in the justice of which I perfectly concur, on the prevalence of a general similarity of the seasons in Europe, within certain latitudes. 'The public, particularly the untravelling part of the public, are hardly aware of the similarity of temperature prevailing throughout what may be called the corn country of Europe—we mean Great Britain, Ireland, the north of France, the Netherlands, Denmark, the north-west of Germany, and in some measure Poland, and the north-east of Germany.' It is then perfectly reasonable to expect, that whenever Providence may favour us with two or three productive harvests in succession, the foreigners will be visited with the same abundance; and although our own produce would then be amply sufficient for our own consumption, and the prices reduced accordingly, yet, if we should have free importations at the same time, we should be liable to be inundated by the surplus produce of the foreigner and suffer a further depression of prices. It is generally believed that should our corn laws be repealed, the foreigner, under the erroneous expectation of an increased demand on our part for his produce, would be induced to extend his tillage, the productive powers of which are almost illimitable. And when the almost boundless extent of the countries from which our occasional deficiencies are supplied, are taken into consideration, it cannot fail to strike us, how small a quantity from each, would make up a whole which would, in a moderately productive year of our own, completely swamp us: for a nation may be poor in superfluity as well as in want. A bee may be drowned in the honey of its own gathering, and on which it subsists; and a people may be ruined by abundance of food.

We cannot forbear giving an account of the imports into Great Britain of wheat and wheat flour in 1831, specifying the countries where they were imported, and the quantities brought from each.

Foreign Produce	14,265	5
Total....	2,311,362	2

The foregoing was one of the largest, if not the very largest, years of grain importation we have had; and yet we see how small is the quantity we derive from any one country. Russia and the United States, from which we have received nearly double the quantity that we have done from any other, yet from neither of these have we imported half a million quarters of bread corn. And what is this from the boundless territories of these countries?—perhaps one ounce per acre. If Russia and America can in ordinary years produce enough for their own consumption, their surplus produce in very productive years, would, if transported to England, be sufficient to smother us. But whether these two countries, and the twenty others from which we import corn in our occasional need, will extend their tillage when our corn laws shall be abolished, we are not prepared to say. Certain, however, it is, that the present advanced price of corn in the continent of Europe, must, ere long, give way. Extremes like this infallibly produce re-action, by one way or other; and however low the prices may have been in Germany, Prussia, and other places, they will undoubtedly sooner or later, experience a like depression again.

It does not follow that an extra production of bread corn in the poorer states of Europe will be met by an increased demand for consumption in these states. The producers of this corn, however plentiful and cheap it may be, can generally no more afford to consume the food they produce, than the children of Bedfordshire can afford to wear the lace they manufacture. The peasants in many parts of the continent are in a state of vassalage or slavery; nearly the whole of the corn their labour produces is taken to the market, and the money proceeds constitute the revenues of the noblemen and great landed proprietors. It seems clear, then, that if any thing should arise to stimulate the productiveness of the neighbouring continental states, whether a repeal of our corn laws or an improved system of agriculture, we should soon see the price of wheat at Danzig, and other foreign ports, down to what it was in the nine years we first quoted, when it averaged only 24s. 7½d. per quarter.

We have already shown, that under a free trade

in corn, the price of home-grown wheat in our market scarcely could be higher than the average price of wheat in Danzig, on account of the superior quality of the latter; which according to the present rate of freights would be fully equal to the cost of transmission. Should then, the time ever arrive, when speculators may be able to land foreign wheat in England, at, or near 30s. per quarter, a host of adventurers will then be found to hoard large stocks in British warehouses to hang in *terrorem* over the home grower. The same fact will operate to retard the purchases of the consumer. Thus the English farmer, through need, consequent on the reduced order of his produce, must press his grain on the market. The speculator, hopeless of prices getting higher, or from pecuniary embarrassment, will be compelled to do the same. The purchaser, seeing the supply exceed the demand, will naturally become cautious; and to what the prices may be reduced under a system of free trade, after a course of plentiful years, is impossible to calculate.

Tooke, in his work before referred to, gives the following calculation, by Gregory King, of the effect of quantity on prices:—

"We take it, that a defect in the harvest may raise the price of corn in the following proportions—

Defect.		Above the common rate.
1-tenth	Raises the price.	.3-tenths
2-tenths		.8-tenths
3-tenths		1.6-tenths
4-tenths		2.8-tenths
5-tenths		4.5-tenths

Tooke, in corroboration of the above rule, says, "There is some ground for supposing that the estimate is not very wide of the truth, from observation of the repeated occurrence of the fact that the price of corn in this country has risen from 100 to 200 per cent. and upwards, when the utmost computed deficiency of the crops has not been more than between one-third and one-sixth of an average." The same is also the opinion of 'Porter,' and was that of Dr. Franklin. If the foregoing calculation be anything near correct, the converse of it will hold good, which may be thus shown, taking the five-tenths to represent an average crop, and exhibiting it as a whole number; the increased quantity or surplussage in tenths; the price represented in shillings and pence—thus s. d.

Average crop, or 1.0 sup- posed to sell per qr. for.	66	0	present price.
Increased to . . 1.2 would be .	45	8	
.. .. 1.4	31	3	
.. .. 1.6	21	8	
.. .. 1.8	15	8	
.. .. 2.0	12	0	

If we are to have a free importation of wheat, I apprehend we must have the same of every other description of grain, and the same reduction in the price of these as of wheat, according to their accustomed proportions of value. But to bring down the price of agricultural produce generally, animal food as well as vegetable food, it is not necessary that there should be a free trade in any thing but wheat; for whatever reduction may take place in the price of that article, every thing else that the farmer produces will be similarly affected. Wheat is, strictly speaking, the standard of value. However we may confound or misapply the terms, the precious metals are only the representatives of value.

Wheat being the staple commodity of life, has been, and must continue in all ages, the only true standard of value. Whatever laws or regulations we may have, every other description of grain must,

in the course of years, bear a proportionate price relative to that of wheat; something like that on which the scale of duties in our present corn bill is calculated, namely, wheat, 72s.; rye, peas, and beans, 45s.; barley, 40s.; and oats 31s. It will be quite unnecessary to enter into an argument or explanation to prove this, which must be self-evident to every one. A word from Adam Smith, however, may not be out of place. In "Wealth of Nations," book 6, chap. 5, Dr. Smith says, 'Corn regulates the money price of all the other parts of the rude produce of the land, which in every period of improvement must bear a certain proportion to that of corn. Woollen or linen cloth are not the regulating commodities by which the real value of all other commodities must be finally measured and determined; corn is. The money price of labour, and of every thing that is the produce of land, or of labour, must necessarily either rise or fall in proportion to the money price of corn.'

These then, Sir, are some of our reasons for thinking, in opposition to your assertion, that corn not only can, but soon will, if the corn laws be repealed, "be had very cheap in England." In the few remaining observations that we may make on the contents of your "Remarks," we shall regard the question of repeal as involving only the expediency or inexpediency of reducing the price of wheat from 60s. to 30s. and consequently every other description of agricultural produce in the same proportion. If the subject were brought forward in this or some other definite form, by Mr. Villiers or Earl Fitzwilliam, in parliament, the question would be much simplified, and the discussion thereon greatly facilitated. Whereas, the way in which it is now introduced as a motion for a committee, or to take into consideration the 9th of Geo. IV. &c., is so lax and indefinite, to give rise in discussion to all kind's of heterogeneous and contradictory opinions. One is for a fixed duty, another for a fluctuating one; some are for Canning's scale, others for Wellington's; another quarrels with the average system, while another applauds it; some are for further restrictions, and others for entire freedom of trade; besides fifty other conceits, shewing the numberless eccentricities which are discovered by wanderings in the mystified and ridiculous mazes of modern political economy.

If the subject were introduced in the shape of a resolution to this effect—"That a reduction of the money price of bread corn would materially conduce to the welfare and prosperity of the industrious classes," the question would then be clear and simple. Should a resolution like this be agreed upon, it would then be soon enough to consider the means by which the desired reduction of prices might be brought about. JOHN ALMACK, Jun.

STATISTICS OF FRANCE.—The Minister of Commerce has published the fourth volume of the "General Statistics of France," being the first part of the division, Agriculture. It comprises the agricultural statistics of the forty-three departments situated east of the meridian of Paris. The following are some of the principal facts to be remarked in it:—"The eastern half of France comprises more than 26 millions of hectares, and nearly 16 millions of inhabitants; it is divided into 177 arrondissements and 19,000 communes. More than a third of the surface is occupied by different crops, and nearly one half, if nursery grounds, osier grounds, and fallow lands be taken into calculation. The gross average produce of corn is 84½ millions of hectolitres per annum; of potatoes 56 millions; and dry vegetables

two millions. Vineyards occupy 900,000 hectares of the soil, and produce upwards of 20 millions of hectolitres per annum, valued at 231 millions of francs, or 263 millions, including the brandy. There are annually made in the same district 3,360,000 hectolitres of beer, and 461,000 of cider. Beetroot occupies under 37,000 hectares; colseed, 116,000 hectares; textile plants (flax, hemp, &c.), more than 100,000 hectares. Mulberry trees, only lately introduced, give 42 millions of francs in produce, of which they are the primary source. The annual value of the total average produce may be thus tabularized:—

Grain.....	950 millions of francs.
Wine.....	264 ditto
Beer and cider.....	52 ditto
Different crops, &c. ..	430 ditto

Total 1,696

In very productive years the total produce is much above 2,000 millions of francs. The quantity of land occupied in pastures of all kinds is 10½ millions of hectares, of which only ½ are in natural and artificial meadow lands. Wood occupies 5½ millions of hectares, producing only 137 millions of francs per annum. The principal species of domestic animals especially belonging to agriculture amount to 25 millions of heads, of which horned cattle form less than one-fifth, sheep 3-5th, swine, 1-10th, and horses 1-20th, representing altogether a capital of 877 millions of francs. A complete agricultural return for France has been attempted at various times since the reign of Louis XIV., but never successfully till the present period, when it has been commenced, and nearly completed, under the auspices of the system of government established in France by the Revolution of 1830. The second volume, completing the agricultural returns, will appear at the end of the current year. The parts of this immense work already published include the General Introduction—Territory and Population—Foreign Trade—and the present division of Agriculture. The remaining volumes, including all the departments of public administration, are in course of compilation.

ROYAL AGRICULTURAL SOCIETY.

At a Council held on Wednesday, June 24, present, His Grace The Duke of Richmond, President, in the Chair, Marquis of Downshire, Lord Portman, Lord Camoys, Thomas Raymond Barker, Esq., John Bennett, Esq., M.P., Thomas William Bramston, Esq., M.P., Edward Buller, Esq., M.P., French Burke, Esq., Colonel Challoner, John W. Childers, Esq., M.P., Hon. Robert Clive, M.P., James Dean, Esq., William Stratford Dugdale, Esq., M.P., Thomas Duffield, Esq., M.P., Humphrey Gibbs, Esq., Edward Greathead, Esq., Henry Handley, Esq., M.P., William Charles Harland, Esq., M.P., Sir John Johnstone, Bart., Francis Pym, Esq., Sir Robert Price, Bart., M.P., Rev. W. L. Rham, William Shaw, Esq. The following gentlemen were elected new members of the Society.

Merrington, D. W., Fulbourn, near Cambridge
 Vaughan, Col. Wright, 2, Chester-street, Grosvenor-place
 Rogers, William, Harold, Bedfordshire
 Rogers, William, Chillington, Bedfordshire
 Parser, William, Caple, Bedfordshire
 Sanders, John, High-street, Bedford
 Ansley, Gilbert, Houghton Hill, Huntingdon, and Wyndham Club, London
 Inghall, C., Swineshead, Boston, Lincolnshire
 Gadsdon, Richard, Heckington, Sleaford, Lincolnshire
 Harbin, George, Newton House, Yeovil
 Combermere, Viscount, 22, Portman-square, and Combermere Abbey, Nantwich, Cheshire

Hall, Jno. Hancock, 3, Essex-court, Temple, and Risley Hall, Derby
 Caldicott, C. M., Myton House, near Warwick
 Hall, J. O., 1, Brunswick-row, Queen-square
 Granger, Joseph, Stretham, Cambridgeshire
 Hall, Thomas, Colnham, Cambridgeshire
 Ficklin, T. J., Cambridge
 Buller, Frederick, Cherry Hinton, Cambridgeshire
 Brown, Samuel, Stanley St. Leonards, Stroud
 Humphries, James, Cawley, Ckelttenham
 Neems, John, Frocester, Stroud
 Barclay, Robert, the Grove, Tooting, Surrey
 Webb, T., Hildersham, near Cambridge
 Webb, J., Horselheath, near Cambridge
 Johnson, Robert, Burwell, Cambridgeshire
 Johnson, Henry, Burwell, Cambridgeshire
 Polimore, Lord, Polimore, near Exeter
 Skipworth, Sir Gray, Newbold Hall, near Coventry
 Cooper, Rev. T. J. Griffin, Arkesdon, Bishops Stortford
 Wyatt, Edward, Upmarden, near Petersfield, Hants
 Dodd, Thomas, Reinham, Sittingbourne Kent
 Lambert, Rev. Burges, Misterton, Crewkerne
 Brown, William, Winterbourne, Stoke, Salisbury
 Fellows, Henry Arthur, Eggesford, Chumleigh, Devon
 Croote, William, Lassford, Chumleigh, Devon
 Craig, Gibson, M.P., Edinburgh
 Peck, Rev. E. M., Wyton, near Huntingdon
 Cheere, Rev. Geo., Papworth Hall, Caseton, Cambridgeshire
 Stebbings, W., Durham Grange, Norfolk
 Hodson, John, Upwell, Cambridgeshire
 Berry, John, Upwell, Norfolk
 Pope, Richard E., March, Isle of Ely, Cambridgeshire
 Pottinger, J., Sonning, near Reading
 Brown, John, Pear-tree House, Elm, Isle of Ely
 Anderson, Richard, Long Sutton, Wisbeach
 Dickens, Francis, Adisham, Wingham, Kent, and Magdalen College, Cambridge
 Girdlestone, Sied, Stillington Hall, Wansford
 Eaton, R. J., M.P., Hitchworth Park, Newmarket
 Nicholls, S., Offord D'Arey, near Huntingdon
 Smith, E. Osborne, Old Broad-street, London
 Babington, C. Carsdale, St. John's College, Cambridge
 Jermyn, Rev. Dr. Bitten, L.L.D., Longstanton House, Cambridge
 Burdakin, Rev. Jas., M.A., Fellow of Clare Hall, Cambridge
 Carter, T. S., Ballards, near Croydon
 Burroughes, Rev. Jer., Lingwood Lodge, Norwich
 Morgan, Philip, Defynnock, Brecknockshire
 Page, Thomas, Ely, Cambridgeshire
 Fryer, John, Chatteris, Cambridgeshire
 Little, H., Whittlesey, Peterborough
 Little, John, Whittlesey, Peterborough
 Dobede, John, Soham, Cambridgeshire
 Jeany, George, Bottisham, Newmarket
 Johnston, John, Cronan, Farnham, Surrey
 Vipan, Walter, Hermitage, Haddenham
 Walbey, Thomas, Sandon, Herts.
 Langley, Thomas, Upton, near Shiffnall, Salop.
 Thisfield, William Barrow, Much Wenlock, Salop.
 Green, John Badger, Heath, Salop.
 Ashdown, George, Tettenhall Wood, near West Hampton.
 Wood, Henry, Allscott, near Broseley, Salop.
 Phillips, Richard, jun., Brockton, near Shiffnall, Salop.
 Smith, William, Sutton Mill, near West Hampton.
 Davis, Thomas, Little Wenlock, Wellington, Salop.
 Norton, John, Little Dun, near Stafford.
 Booth, William, Priorsley, near Shiffnall, Salop.
 Aston, John, Seesdon, near Wolverhampton.
 Baker, John, Bridgeworth, Salop.
 Sibley, Robert, Kingsborne Green, Harpenden, Herts.
 Packe, Rev. Augustus, Welton Rectory, Loughborough.
 Lyon, Edmund H., Horstead House, Norwich.
 Holmes, Rev. John, Brooke Hall, Norwich.
 Wagner, G. H. Malcolm, Herstmonceuse, Battle, Sussex.

Walkias, Rev. F., King's Walden, Hitchin, Herts.
 Hayden, James, Arrington, Cambridgeshire.
 Wilkinson, George, Harperley, Durham.
 Hallstone, Rev. John, M.A., F.R.S., Vicarage, Bottisham, Cambridge.
 Wright, J., jun., Dudwis, Barton, Norwich.
 King, Rev. John, Cutcombe, Dunster, Somerset.
 Youngman, William, Girtton, Cambridgeshire.
 Hall, Wilson, Landbeach, ditto.
 Hall, William, ditto, ditto.
 Granger, John, Stretham, ditto.
 Iviatt, James, Cottenham, ditto.
 Iviatt, Robert, ditto, ditto.
 Minworth, G. Wakefield, Birmingham.
 Carter, James, Barton Hopwas, Tamworth.
 Dexter, Joseph, Bramcote, ditto.
 Vipian, John, Ely Sutton, near Cambridge.
 Saberton, William, Ely, Cambridgeshire.
 Copley, James, ditto, ditto.
 Evans, H. R., jun., ditto, ditto.
 Bradley, John, Blyth, Retford, Notts.
 Hodgkinson, Richard, Osberton Grange, Worksop, Nottinghamshire.
 Savill, John, St. Neots, Hunts.
 Kemp, Jesse, Utterby Grove, Louth.
 Rodwell, George, Burnham, Deepdale, Norfolk.

The Rev. W. L. Rham submitted to the inspection of the Council a specimen of winter Barley of an extremely prolific and hardy kind, grown on his farm at Winkfield, from seed transmitted to him from Belgium. It is the sort of barley known in France and Belgium as "Escourgeon," and a single seed of it produced 17 ears, containing an amount of nearly 15,000 grains of barley. The original seed was plump, round, and of a good colour, but rather inclined to be thick-skinned, and Mr. Rham considered this barley as the most prolific he had yet met with. Mr. Rham has presented to the society the volume of his "Outlines of Flemish Husbandry," and the Yorkshire Society the new part of their printed proceedings.

At a monthly meeting of the Council, held on Wednesday, July 1, present, Henry Handley, Esq., M.P., in the chair; the Hon. Robert Clive, M.P.; Thomas Raymond Barker, Esq.; Colonel Challoner; J. W. Childers, Esq., M.P.; James Dean, Esq.; Humphrey Gibbs, Esq.; Stephen Grantham, Esq.; George Hemington Harris, Esq.; W. Goodenough Hayter, Esq., M.P.; W. Fisher Hobbs, Esq.; Sir John Johnstone, Bart.; John Kinder, Esq.; Sir Charles Lemon, Bart., M.P.; Rev. W. L. Rham; Edward Aysbford Sandford, Esq., M.P.; William Shaw, Esq.; Walter Strickland, Esq.

The Mayor of Manchester, and Mark Phillips, Esq., M.P. for Manchester, attended the Council, the Mayor to express on the part of the town and corporation, and Mr. Phillips, on the part of his constituents, the satisfaction it would give them to receive the Society at Manchester next year, and the hope they felt that the next annual meeting in the country would be held in that town, where every effort would be made to render the meeting agreeable, and to promote the successful advancement of the great and national objects of the Society.

The CHAIRMAN returned the unanimous thanks of the Council to the Mayor and Mr. Phillips for this gratifying mark of their attention, and next Wednesday was fixed as the day when the determination of the Council on the place of meeting next year would be discussed and finally determined.

The following two new bye-laws, of which due notice had been given by Mr. Childers, were then passed:—

1. The place of meeting in country shall be settled by the Council at the first Wednesday in May, and declared at the anniversary meeting in the year preceding such meeting.

2. All prizes shall be settled by the Council at or before the last Wednesday in June the year preceding;

and no new prize shall be offered, or increase of an old one shall be made, after that time.

It was also resolved, that the Secretary shall give due notice to the Members of the Council of the day appointed to settle the list of prizes for 1841.

The Duke of Richmond proposed the Marquess of Douro, and David Barclay, Esq., the venerable Lord Lysedoch, as Members of the Society.

Sir Robert Bateson, Bart., M.P., of Belvoir Park, and Edmund Mac Donnell, Esq., of Glenarm Castle, were, on the motion of the Marquess of Downshire, elected Governors of the Society.

The following gentlemen were elected new Members:—

Algar, R. F., West Rudham.
 Ambrose, W. Cole, Quy, Cambridgeshire.
 Allsop, John, Basingthorpe, Lincolnshire.
 Browne, E., Silsoe, Beds.
 Barrett, G. A., Reading, Berks.
 Banks, Rev. J. S., Hemmingford Grey, Hunts.
 Bawyer, Thomas, Buckden, Hunts.
 Bawyer, Wm., Southoe, St. Neots.
 Bawyer, George, Deddington, Buckden.
 Beaven, James, Thornham Farm, Seend, Devizes.
 Curtis, John, Jun., West Rudham.
 Curtis, John, West Rudham.
 Chamberlin, Wm., Westby, Lincolnshire.
 Clowes, Francis, Hemaby, Norfolk.
 Cotes, Rev. C. Grey, Stanton, St. Quintin, Chippingham.
 Calthrop, Rev. Wm., Corpus College, Cambridge.
 Colville, Rev. A. A., Lincolnmere Rectory, Bury St. Edmunds.

Drake, Sir T. E., Nutwell-court, Devon.
 Dickinson, Thomas, Great Ponton Lincolnshire.
 Drummond, Rev. A., Charlton Rectory, Kent.
 Dawson, Richard, Withcall House, Louth.
 Eades, Francis, Cambridge.
 Ellis, Joseph, Threplew, Cambridgeshire.
 Ellis, G. Ingle, Skepreth, do.
 Ezall, Wm., Reading, Berks.
 Frere, P. H., Downing College, Cambridge.
 Floyer, J. Wadham, Ketaby House, Louth.
 Feummon, Charles, Beckford Hall, Tewkesbury.
 Fawles, Wm., Market Lavington, Devizes.
 Griffin, W. E., Wermington, Peterborough.
 Goodwin, S. C., Huntingfield House, Yoxford.
 Greetham, Thomas, Stainsfield, Wragby.
 Green, John, Grantham, Lincolnshire.
 Gibson, Thomas, Basingthorpe, Lincolnshire.
 Gibson, Richard, Belvoir Inn, Leicestershire.
 Goodwin, Shadrach, Hemel Hempstead.
 Horton, Richard, Audley End, Saffron Walden.
 Hall, Lieutenaut, Colcoel.
 Hurwood, George, Ipswich.
 Harris, Wm., Somerby, Grantham.
 Hand, Robert, Woodsthorpe, Lincolnshire.
 Haylock, John, Balsam, Cambridgeshire.
 Hammond, J. W., Wistaton Hall, Nantwich.
 Harlock, Wm., Ely, Cambridgeshire.
 Hicks, J., Walton Hall, Thorp, Essex.
 Josselyn, J. jun., Belstead, Ipswich.
 Jones, Wm., Harrington, Shiffnal, Salop.
 Lakon, Sir E. H. K., Ormesby, Great Yarmouth.
 Lynn, Robert, Stroxtan, Grantham.
 Lushington, Rt. Hon. S. R., Merry Hill, Watford.
 Langley, Smyth, M.P., Kelvedon, Essex.
 Meeson, John, Grays, Essex.
 McPherson, J., Lynn Regis, Norfolk.
 Martin, Henry, Littleport, Ely.
 Martin, Wm., Downham, Ely.
 Mytton, Thomas, Shipton Hall, Much Wenlock, Shiffnal.
 Newbett, Edward, Kimpton, Leicestershire.
 Padmore, Charles, West Rudham.
 Purkin, Wm., Withinfield, Essex.
 Phelps, Charles, Briggs Park, Ware.
 Pulnois, Wm., 12, Abbey Road, St. John's Wood.
 Pigott, Wm., Dulingham Hall, Newmarket.
 Pells, Edward, Culpho, Suffolk.
 Phillips, C., Margaret, Rootling, Essex.

Rous, Rev. T. Manners, 38, South Street, Park Lane
 Stilwell, James, Walton-on-Thames
 Scoffin, Charles, Stoke, Grantham, Lincolnshire
 Smith, John, Cambridge
 Sheldrake, R. E., North Hill, Colchester
 Surridge, I. J., Feering, Kelvedon, Essex
 Thorp, J. Sydney, Chippenham Park, Cambridge
 Townley, Rev. Gale, Beaupre Hall, Wisbeach
 Tredecroft, Henry, Warnham Court, Horsham, Sussex
 Vipan, Walter, Sutton, Ely
 Walker, Thomas, the Bank, Doncaster
 Widnell, Samuel, Grantchester, Cambridgeshire
 Wyles, Thomas, Little Ponton, Lincolnshire
 Wright, R. S., Downham Market
 Walbey, Henry Widdial, Bury, Herts
 Welchman, Robert, Hockley House, Southam
 Wilkin, Charles, Tolleshunt, Kelvedon, Essex
 Wood, John, Stowmarket, Suffolk
 Yate, Joseph, Madeley, Shiffnal, Salop

GOVERNORS.

Bateson, Sir Robert, M.P., Belvoir Park, near Belfast, and 30, Pall Mall
 McDonnell, Edmund, Glenarm Castle, Glenarm, Ireland, and Mivaris Hotel, London.

PRIZE ESSAYS.

The following adjudications of the Premiums in this department have been already made:—

To Mr. WILLIAM E. GEACH, of Tywardreath, Lostwithiel, Cornwall, the premium of Ten Sovereigns, for the best Essay on the Storing of Turnips.

To Mr. WILLIAM LINTON, of Sheriff-Hutton, near York, the premium of Twenty Sovereigns for the best Essay on the Admixture of Soils.

To Mr. M. M. MILBURN, of Thorpfield, near Thirsk, Yorkshire, the premium of Twenty Sovereigns for the best Essay on Early Spring Feed.

To Mr. CUTHBERT W. JOHNSON, of Gray's Inn, the Gold Medal for the best Essay on Plantations.

To Mr. CUTHBERT W. JOHNSON, of Gray's Inn, the premium of Ten Sovereigns for the best Essay on Gypsum as a Manure.

The premium for the best Essay on the Rotation of Crops for Heavy lands, is still under consideration. None of the remaining Essays were considered by the Judges as being of sufficient merit for a prize.

Communications were received from Lord Western, Mr. Davies Gilbert, Mr. Wilbraham Egerton, the Secretary of the Manchester Agricultural Society, and Mr. Schjölter, of Norway: and Mr. Rodwell, of Alderton Hall, presented a specimen of his Italian Ryegrass.

At a council held on Wednesday, the 8th of July, present, His Grace the Duke of Richmond, president (in the chair), Marquis of Downshire, Earl of Euston, Lord Portman, Lord Rayleigh, Lord Bridport, Hon. R. Clive, M.P., D. Barclay, Esq., J. Bennett, Esq., M.P., T. W. Bramston, Esq., M.P., T. R. Barker, Esq., J. R. Barker, Esq., Col. Chaloner, J. W. Childers, Esq., M.P., R. M. Gillies, Esq., Henry Handley, Esq., M.P., T. L. Hodges, Esq., M.P., P. Pusey, Esq., M.P., E. A. Sanford, Esq., M.P., W. Shaw, Esq., W. R. C. Stansfield, Esq., M.P., H. Wilson, Esq.

Neil Malcom, Esq., of Kilmartin, Lockgilphhead, Argyleshire, and Great Stanhope-street, London, was elected a governor, and one hundred and sixty-six gentlemen members of the Society.

On the motion of Lord Portman, seconded by the Hon. Robert Clive, M.P., it was resolved that Liverpool should be the place of the Annual County Meeting of the Society, in the year 1841.

WEDNESDAY, July 15. — At a meeting of the Council: present—His Grace the Duke of Richmond, President (in the chair), the Marquis of Downshire, Earl Spencer, T. W. Bramston, Esq., M.P., Henry Handley, Esq., M.P., W. Fisher Hobbs, Esq., Francis Pym, Esq., Rev. W. L.

Rham, E. A. Sanford, Esq., M.P., William Shaw, Esq., Rev. J. R. Smythies, Mr. Druce, of Ensham, near Oxford, and Mr. Graburn, of Sleaford, were requested to sow a portion of the Prize Wheat selected as the best exhibited, and to report the result to the Society.

Earl Spencer gave notice that he should move, at an early Council, that the Annual County Meeting for 1842 should be held at some place within the range of the Hereford county.

THURSDAY, July 16.—A Finance Committee, David Barclay, Esq., in the Chair, and a Council, J. W. Childers, Esq., M.P., in the Chair, were held in the forenoon, for the purpose of calling in all claims on the Society, and of authorizing the Stewards of the yard to discharge all miscellaneous bills to the amount of 400*l.*, leaving a discretionary power with Mr. Pym to pay all such small bills or other accounts as he might consider desirable. On the afternoon of the same day, Philip Pusey, Esq., M.P., the new President of the Society, held a Council, at which were also present, the Marquis of Downshire, Earl Spencer, Thos. Raymond Barker, Esq., Henry Boys, Esq., John Ellman, Esq., Henry Handley, Esq., M.P., C. Hillyard, Esq., Samuel Jonas, Esq., Francis Pym, Esq., Rev. W. L. Rham, William Shaw, Esq.

Alexander Francis Campbell, Esq., of Great Plumstead, near Norwich; Charles Robert Scott Murray, Esq., of Danesfield, near Marlow; and William Hale, Esq., of Kingsmalden Park, near Welwyn, were elected governors, and two hundred and thirty-four gentlemen members of the society.

THE GREAT YORKSHIRE AGRICULTURAL SOCIETY'S SHOW,

AND MEETING AT NORTHALLERTON.

Preparations are actively making for the ensuing meeting. Two capacious fields are selected for the show-yard for the stock, where the pens, &c. will be erected, and one of the largest and best shows of short-horns is expected that has ever been witnessed in England. The bulls especially are expected to be very numerous, and from the herds of the first short-horn breeders in the county who reside in the district. The stock will be in the field by seven o'clock in the morning; members of the society will be admitted by nine; the public, by 2*s.* 6*d.* tickets, at ten, and by 1*s.* tickets, at twelve. On Tuesday, August 4th, the Central and Local Committee dine together at the Golden Lion Inn, and on the 5th, the show day, the great dinner will be held in the Pavilion, erected for the purpose in the quadrangle of the Court House, capable of dining twelve hundred and nine persons. The building is covered with transparent water-proof canvass, and is an exceedingly beautiful room. The dinner will take place at three o'clock, Earl Spencer, the President, will preside. The exhibition in the show fields embraces cattle, sheep, horses, pigs, poultry, implements, seeds, roots, &c. Several temporary buildings are being erected to accommodate the horses, stock, &c., and every facility seems to be offered to accommodate the large influx of agriculturists, breeders, &c. who are expected to attend.

On Thursday, August 6, the annual meeting of the society will be held, and the prizes distributed. A great Horticultural Exhibition will also take place in the quadrangle of the Court House.

Mr. Wetherell will also sell the stock which may be offered on that day.

“LITTLE WONDER;”

WINNER OF THE DERBY.

(PLATE II.)

The marvellous little horse under consideration is, if we mistake not, the most diminutive Derby nag on record; he is under fifteen hands. He has many racing points in his favour, which will be seen by the following description: His head is small, his neck short and strong; his shoulders muscular and oblique; not very high in the withers; large and long arms, but legs short; pasterns long; feet good and open; the fore and back ribs large; very wide in the hips; very drooping quarters, and long; large in the stifles and thighs; and stands over little ground in the stable. His colour is a beautifully brilliant bay: he stands fourteen hands three and a half inches high, and his temper is particularly good. Some discontented hypercritics have endeavoured not only to run down Little Wonder's performances, but to question the purity of his blood. All this is in bad taste. He comes of some of our very best stock, and did time and space permit, we would convince these growling sceptics that some of the very best blood that England can produce flows in the veins of Little Wonder. The Stud book, however, will remove all doubts on this subject, and to that we must refer. As we cannot, therefore, indulge in a genealogical discussion at this moment, or *run up the family tree* to satisfy the jealousies of a disappointed few, we will content ourselves by merely stating that Little Wonder was bred in 1837 by Mr. Nowell, of Underley, and purchased by Mr. Robertson, his present owner, at the annual sale of Mr. Nowell's yearlings, at Doncaster, in 1838. He (Little Wonder, not Mr. Nowell) is got by Muley (by Orville, out of Sir Chas. Banbury's Eleanor) out of Lacerta (bred in 1816 by Lord Rous, and the dam of Marvel, Cestus, &c.) by Zodiac, her dam Jerboa, by Gohanna, out of Camilla by Trentham, Coquette by the Compton Barb, out of Sister to Regulus. By this it will be seen the little 'un does not come from a very bad sort. A veritable "John Bull" when he loses his money must grumble—it is in his nature, and his ill humour must have vent. It is true that the previous performances of Little Wonder were not of a character to warrant his winning the Derby. With this we have nothing to do, neither have the public. He *did* win the Derby, and well too;—beating the cracks in right good form, and doing his work right cleverly, thanks to Macdonald who did wonders with him.

The performances, if they may be so termed, are comparatively nothing. At the Newmarket Second October Meeting of 1839, Little Wonder started for the T.Y.C. Plate on the Tuesday, and not placed, Warden being first, Richmond second, and Jeffy third; Assassin and several others not placed. Started for the Nursery Stakes in the Houghton Meeting with 7st. 4lb. on his back, and was second, Assassin with 6st. 10lb. winning cleverly. These, the Derby, and the Ascot stakes at Ascot (where he run second), have been the only performances. Little Wonder is a large horse in a small compass; some of his points display extraordinary power; he is handsome withal in spite of his drooping quarters, and one of the most splendid colours we ever saw. He has earned his laurels well, and Mr. Robertson may well be proud of his *Bays*, for if they are all like Little Wonder, his horses are worth a kingdom.

SWEDE TURNIPS.—CHALLENGE ACCEPTED.

TO THE EDITOR OF THE MARK-LANE EXPRESS.

SIR,—My attention having been drawn, by a paragraph in your paper of the 1st inst., to the challenge made by Mr. Houghton, of Broom-hall, that he would show at Tring, on the 18th Dec. next, fifty Swedish turnips, against any man in England, I beg to say, that my fingers itch exceedingly to take up the gauntlet so thrown down by the worthy gentleman. I am willing to show fifty of my own growth against fifty of his growth; but, before I buckle on my armour, I should like to be informed, through the medium of your paper, the exact terms or conditions of the turnip tournament.—I am, sir, your obedient servant,

ROBERT MATSON.

Wingham, June 5, 1840.

THE SWEDE TURNIP CHALLENGE.

TO THE EDITOR OF THE MARK LANE EXPRESS.

I perceive by your paper of last week that Mr. Robt. Matson of Wingham, appears anxious to take up the gauntlet to shew fifty Swedish Turnips against me, if he knew the terms.

I shewed at the Tring Station fifty Swedish Turnips against a gentleman in that neighbourhood, and they were weighed, after having been washed and the tops and roots taken off close, and the weights of them appeared in the Mark Lane Express and several other newspapers.

The challenge I then made was to shew those fifty Turnips against any man in England, weight being the criterion, to be grown in a field of not less than seven acres, and after a crop of white grain; the Turnips remained there for months, if Mr. Matson had thought proper to accept it.

If he thinks he can beat them this year, I am ready to make a wager for any sum not less than one sovereign, and not exceeding twenty sovereigns, that he does not produce, on the 18th of next December, fifty Swedes heavier than those I produced last year, subject to the conditions stated above.

Not being in the habit of writing in newspapers, allow me to beg of you to call the attention of your readers to the necessity of establishing a rural police force throughout every county in the kingdom; I am satisfied it would be very beneficial. I had, a fortnight since, ten sheep stolen in the Vale of Aylesbury, and notwithstanding we have all formed an association, and offer 110 guineas reward, it still continues, and now there is scarcely a night passes but some depredations are committed. I understand some are against it on account of the expenses, but I feel satisfied we should be repaid. I am, Sir, your obedient servant,

JOHN HOUGHTON.

Broom Hall, Sunning Hill, June 11.

SEED TURNIPS.—CHALLENGE.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—It was my wish to have paid earlier attention to Mr. Houghton's letter, published in your number of the 15th inst., but I was so desirous of ascertaining the weights he refers to, that I let pass a week or two to overhaul at intervals old newspapers, but did not in the course of my rummage meet with such account; however, my recollection of the turnips shewn by that gentleman at Tring is sufficiently clear, and I feel no hesitation in accepting

his challenge. As the main object of all such emulation is the advancement of this or that branch of agricultural pursuits, a small wager will answer the purpose as well as a large one, and accordingly I will, with Mr. Houghton's leave, name the harmless sum of *five sovereigns*. The question being decided as to my fifty turnips against the recorded weight of the fifty already shewn at Tring, I should vastly like to have a supplementary contest with fifty of my turnips against an equal number of Mr. Houghton's ensuing crop, at the Smithfield Cattle Show, for another modest bet of another five sovereigns.

I do not propose to alter the conditions agreed upon for the Tring exhibition, but if ever I make any future trial for the championship of the turnip, I shall require additional terms; the mere weight of a given number of selected turnips, is not in my opinion, a satisfactory criterion; I should therefore expect, firstly, that the weight should be the weight of produce per acre; secondly, symmetry of bulb; thirdly, genuineness of bulb; and fourthly, quality, another essential point, evenness of leaf, cannot be insisted on, when the specimens are topped and tailed.

By quality I do not mean that thicknecked monster turnip sometimes shewn at agricultural meetings, and which excites wonder and admiration until it is cut and tasted, when it turns out to be woolly, stringy, juiceless, with ill flavoured flesh, with gigantic leafage, and altogether fit only for the descendants of "the ram of Derbyshire" celebrated in ancient song. No, no, by quality I mean the fulness of saccharine juice, which delights the palate of cattle, and clothes their bones with flesh at a rate akin to railway speed, that gives the clear crisp slice, which flies like glass before the knife and between the teeth of distinguished noblemen, gentlemen, and yeomen agriculturists, and of worthy Londoners too, whom I have seen crowding around my standing at the Smithfield Cattle Show, munching slice after slice, as if they were astonished how very few removes it appeared to be from the golden pippin or pine-apple. I mean that turnip, six, eight, or ten lbs., round as a cricket ball, and which melts in the mouth of those unerring judges the pigs, who will absolutely fatten on these Swedes, which hares, rabbits and rooks greedily, while they will do no more than look and smile at others closer at hand, and which, moreover, become leathery in a dry season, whilst my sorts remain as round, as sweet, and as good as good can be.

I am, Sir, your obedient servant,

Wingham, June 24.

ROBERT MATSON.

CAMBRIDGE MEETING.

We subjoin a cut of Messrs. Garrett's Machine, For Messrs. Ransome's, see plate.

The following is an account of the work performed by each of the thrashing machines at work on Tuesday, at the farm on the Hill's Road:—

PRESENTATION OF A PIECE OF PLATE TO THE DUKE OF RICHMOND BY HIS SUSSEX TENANTRY.

On Thursday, July 23, a magnificent piece of plate, the gift of the tenantry on the Goodwood estate, was presented to his Grace the Duke of Richmond. The presentation took place in the tennis court, where an elegant *déjeune à la fourchette* was prepared.

The chair was filled by T. Halstead Esqr., of the Woodcote farm, whose ancestors and himself have been on the Goodwood estate for upwards of 130 years. The Duke of Richmond sat on his right hand, and he was supported by the Earl of March and nearly sixty farmers and gentlemen holding land &c. under his Grace. The piece of Plate, the design of which for such an occasion was most appropriate, represented a shepherd boy attending his flock, the sheep being exquisitely modelled in silver, his dog is at his feet, and a cow behind him. From the centre springs a magnificent candelabra, around the branches of which the ivy, the badge of the Gordon clan, is entwined,—was placed at the head of the table.

When the usual preliminary proceedings had been gone through the Chairman and the tenantry rose, and the former addressed the noble Duke in the following terms: He said that he rose to perform a pleasing and gratifying duty, and he felt most deeply the honour which had been done him in selecting him to fill the situation he then held on so interesting an occasion; and while he regretted that the choice had not fallen on some one better qualified to express the sentiments of those around him, yet he trusted he might be permitted to say that no one could feel more sincere delight in being the medium through whom those sentiments were conveyed to the noble Duke. It was their good fortune to be the tenants not only of an indulgent and a liberal landlord, but of a kind and sincere friend. The noble Duke was too well known there to render it necessary for him to add one word of compliment or eulogy, but he could not but advert to the distinguished situation which his grace had lately filled as President of the Royal Agricultural Society, a society in which men of the first scientific attainments pressed forward to co-operate with the practical farmer. They had lately had the satisfaction of seeing their illustrious friend presiding at the great anniversary meeting at Cambridge, where, as at every other time, and every other place, he spared no exertions to promote the welfare and prosperity of his fellow-men. He would only recal to their recollection the scene which that Hall presented a few weeks since at the meeting of the West Sussex Association, where the noble Duke was surrounded by the farmers and labourers of the western division of the county, zealously and energetically supporting the interests of both, and more especially, he would add of the latter. I will now (said Mr. H.) without detaining you longer, at once proceed to the pleasing duty which devolves upon me:—

“My Lord Duke, in the name of your Grace's Sussex tenantry I have the honour to present and request your Grace's acceptance of this piece of plate, as the memorial of the high estimation we entertain for your Grace as our landlord and friend; and may Providence send down its blessing, and grant your grace a long and happy life to preside over a deserving tenantry.”

The Duke of Richmond then rose and was most enthusiastically cheered; he said, that surrounded as he then was by so numerous and respectable a body of men, by tenants, many of whom had known him from childhood, and from whom he had ever received the greatest marks of kindness, and who had now met to offer him so splendid and distinguished a proof of their attachment, they might well believe he found it difficult to gain words to express his feelings; there were emotions too deep for utterance, there were feelings which words could not express, and such were those with which at that moment he was overpowered. I accept your present, continued the noble Duke, I accept your kind and generous present with feelings of the deepest gratitude; as an heirloom in my family it shall descend to my children's children. My eldest son is now among you, a witness to the reception his father meets with from the farmers of Sussex, and when it shall please Providence to remove me from this earthly scene, may he learn to look on them as his best and warmest friend. From the first moment of my coming among my tenantry to the present, I have never received an angry word, on the contrary, they have ever sought opportunities of shewing kindness to me and mine, I can only hope that they may long continue to hold their farms in health and prosperity. If your gift (said the noble Duke) is creditable to me as your landlord, it is doubly so to you. It will shew, and I speak it with pride and gratification, the good will and attachment which exists on the part of my tenantry and myself, and when I can forget this noble proof of your feelings, may you then forget me. The noble Duke sat down amidst loud cheering.

After the conclusion of the repast, his Grace at parting took occasion to offer a few remarks. He alluded to the late Meeting at Cambridge, and the results which were likely to spring from the Royal Agricultural Society, where men of all ranks met for one common purpose, and where politics were excluded; the statesman, the landlord, the farmer, and the labourer were joined for one great and good purpose, at one time endeavouring to bring to bear on agriculture those arts, by the intervention of which perfection and wealth had flowed on the other branches of national industry; and at another endeavouring to ameliorate the condition, both moral and intellectual, of the labourer. His Grace, after again alluding to the object for which they were assembled, and again endeavouring to express the feelings which almost overpowered him, then left the Hall.

The plate was manufactured at Gerrard's, Haymarket, London, and was an exquisite work of art.

ON PURCHASING NITRATE OF SODA.

SIR,—As Nitrate of Soda is much used as a manure, I beg through the pages of your magazine to caution those agriculturists who intend to use it, to be very careful in procuring it from respectable parties, as a common and low priced article is now offering supposed to consist of the common soda and salt; this forms a muriate instead of a nitrate of soda, and has a tendency to destroy vegetation. I remain, Sir, yours obediently,

July 9th.

A FARMER.

AGRICULTURAL REPORTS.

GENERAL AGRICULTURAL REPORT FOR JULY.

[Since this report was written the weather has all the appearance of being settled harvest weather; should such be the case, it will be impossible to estimate the extent of improvement which may take place, in the wheat crop more especially.]

During the whole of this month, the greatest anxiety has been manifested, not only by those immediately engaged in agricultural pursuits, but, likewise, the community at large, respecting the growing crops of all descriptions of the soil's productions, but more particularly those of wheat, barley, and oats. This state of things was greatly heightened towards the close of the above period, owing to the accounts, received from our corn districts, being of a very unsatisfactory, and, in many instances as regards wheat, of an unfavourable character. Having ourselves, as has been for many preceding seasons (from the conviction that personal observation would the more readily enable us to convey to the minds of our readers every *fact* connected with agriculture, than the mere reliance on reports transmitted possibly by interested parties) taken an extensive tour in most of the midland, northern, and western counties of England, we are enabled to speak definitively of the present appearances of the wheat plants, as also of the future prospect of the agricultural community, while we cannot but express our regret at being compelled honestly to confess that, to us, they are very far from flattering. In Essex, the wheat appears, on good soils, to have progressed towards maturity surprisingly well, though under by no means favourable auspices, and the yield is fully anticipated to amount to a full average; while on heavy and poor lands, a great deficiency is apparent, the stalks being extremely thin and stunted. Throughout Suffolk, Kent, Sussex, Cambridgeshire, and Yorkshire, the appearances do not warrant an improvement on last year's produce. In turning, however, our attention to the south, we have great cause for congratulation, the wheat, in that quarter, being, we are truly happy in bearing testimony, in the most perfect order, and every farmer with whom we have conversed, and over whose lands we have travelled, having expressed himself in high terms of all passing around him, whilst no doubt is entertained of the forthcoming harvest of that description of grain being great. At no previous corresponding period of the year, have we been called upon to record in a more favourable light the growth of barley; indeed, although an unusually large number of accounts have been transmitted to us, from the most extensive barley growers in England, we are firmly of opinion that this year's will greatly exceed that recollected for many past seasons. Oats will, doubtless, be very short in the straw, yet the yield is expected to come up to a fair average. In many sheltered situations, the fly

appears to have committed extensive ravages upon both beans and peas, in consequence of which, and the limited stocks on hand, their value is pretty generally expected to be considerably enhanced, during the next three months; hence large supplies of foreign will be released for home consumption, at an almost nominal duty.

The late considerable rise in the currencies of wheat, in almost every market in the kingdom, and the consequent fall in the duty to 16s. 8d. per quarter, have induced many persons to suppose that the quantity of grain in the hands of our farmers is extremely small. That it is much less than ought to have been perceived at this momentous crisis, we have little cause to doubt, but it is to be sincerely desired that it is sufficiently large to prevent the importation for home consumption of any very considerable quantity of foreign. Should the latter be the case a great derangement will inevitably take place in our monetary system, and disastrous consequences will be the result.

Harvest appears to have already commenced on some highly cultivated lands in Devonshire—a correspondent under date the 24th inst., writing as follows:—

"The corn harvest has commenced in this county. On Wednesday, a field of wheat, the property of E. Gatty, Esq., was cut in excellent condition, and we are now busy in cutting oats." The same intelligence has, also, reached us from several other districts.

The fluctuations in the atmosphere have been almost without a parallel, the wind having, on many occasions blown from all points of the compass in less than 24 hours; nevertheless, the effect upon the crops has been, comparatively speaking, trifling.

From Scotland our accounts are, on the whole, favourable, the wheat being described as already in full bloom, with every prospect of a fair average return; but the harvest is expected to be a protracted one. The value of wheat has been, as with us, on the advance, with very moderate supplies offering, while barley and oats, the shipments of which to the English markets have proved, the time of year considered, extensive, have well maintained their position.

In Ireland the grain plants are looking unusually thin, with every prospect, at least judging from present appearances, of a bad crop of most kinds of the soil's productions. Wheat, barley, and oats have been held at high rates.

Notwithstanding the crop of hay has been gathered in tolerably good condition, the swathe has fallen considerably short of the expectations of the growers; indeed it must be considered one of the lightest growth recollected for a series of years past; still, however, a good second crop is fully expected.

The following is our usual monthly statement of the supplies and prices of fat stock exhibited and sold in Smithfield Cattle Market.

The supplies have consisted of 10,590 beasts, 149,680 sheep and lambs, 1,200 calves, and 3,840 pigs, while the prices have ranged as follows:—Beef, from 3s. 4d. to 4s. 8d. per 8lbs.; Mutton, 3s. 6d. to 4s. 8d.; Lamb, 5s. to 6s.; Veal, 4s. to 4s. 10d.; Pork, 4s. to 5s.

A STATEMENT and COMPARISON of the SUPPLIES and PRICES of FAT STOCK, exhibited and sold in SMITHFIELD CATTLE MARKET, on Monday, July 29, 1839, and Monday, July 27, 1840.

At per 8lbs. to sink the offals.

The arrivals of slaughtered meat up to Newgate and Leadenhall markets from Scotland and various distant parts of England, have been wholly unimportant, yet the sale for them, on account of their being received in bad condition, arising from the weather, has been heavy, at low currencies.

WEST CUMBERLAND.

It has seldom, if ever, been our lot to witness, not amongst farmers alone, but in the public mind generally, a greater anxiety than is at present manifested respecting the grain crops, owing to the threatening aspect of the season. For the last two months we have experienced wet, cold, and ungenial weather, which for the last season has been unseasonable in the extreme, and, with the exception of a day now and then, being as boisterous and as cold as in winter. Yesterday was St. Swithin's day, and the lachrymose Saint shed his tears in abundance, which the believers in old saws look upon as a bad omen for improvement. Great apprehensions are entertained for the wheats at this season, particularly those which were early sown, and which are now in bloom. The thin crops seem blown loose by the boisterous winds, and are very much laid down; but the more sheltered and backward crops have not yet sustained any injury. The early sown barley, and indeed all upon dry soils, seem highly promising; but the colder soils and the later sown barley appear to promise only indifferently. Oats everywhere look well. Indeed, generally speaking, we never remember having seen finer crops of this prolific grain. Sown grass hay is generally considered thin, but old grass and meadow hay are everywhere abundant. A considerable portion of the seed hay has been placed under cover, during favourable intervals of weather, in pretty fair condition; but little of the old grass is yet secured, and the early part of the meadows are only now being cut. The early planted potatoes are most favourably spoken of in all parts, and all that we have seen of them present a most luxuriant appearance. Some have already been brought to market, and are really excellent. Those, however, which were late in being planted, and such as were set upon cold soils, are by no means so promising, and we are afraid, unless we have a favourable alteration in the weather, they will be a failure to some

extent. The Swedish turnips, sown early on good dry soils, promise well; those on cold retentive soils are making little or no progress in consequence of inclement weather, notwithstanding their recently promising appearance. The later sown common turnips present by no means a very promising aspect on cold soils, or where the land is wet, and we have heard many farmers already express their intention of ploughing them down, which will tend greatly to raise the price of fat beasts during winter. The fallow ground, generally speaking, is in a very filthy state—a circumstance entirely owing to the unfavourable weather, and not likely to be much improved at this late period of the season. The present state of the fallows augurs very unfavourably for the wheat crops on fallow ground in 1841. The grass lands for pasture, which are good and dry, are pretty full of keep; but the grass on cold lands when bitten does not rise again;—these lands have lost their colour, and their supply of keep seems very scanty. Stock, owing to the inclemency of the weather, are not doing well, and fat stock remains dear—choice ones scarce. Lean stock are not in such lively request as of late; both cattle and sheep are lower. Horses at different fairs have recently met with only moderate markets, with the exception of choice animals, which are always in request, and out of season. Pigs are more plentiful, and somewhat reduced in price. Our grain markets, throughout the district, are very scantily supplied with home-grown produce. The wheat, notwithstanding the advanced state of the season, is generally poor, and principally used for making ship-bread. There are very few stacks to be seen in the country of any kind of grain. The markets, however, continue to be plentifully supplied with foreign and Manx grain, which are much enquired for, and meet ready sales at stationary prices. The late drenching rains, and the present cold and gloomy state of the atmosphere, have been pretty general throughout England, Ireland, and Scotland, and should they continue there is every probability of an advance taking place in the price of grain. Trade is at present unusually languid and money scarce, and the heavy remittances for foreign grain tend to make the scarcity of money still more seriously felt. It may seem somewhat strange to many of our country friends to learn that West Cumberland alone, during the last two years, has remitted more than three hundred pounds per week for foreign grain. Should the present unfavourable weather continue much longer, we shall have to add, to the three out of four already past, another adverse season, the effects of which will be most disastrous to the English farmer, as well as to the poor. Should the season continue unfavourable the farmers who have been struggling with the effects of the late bad seasons have no prospect but that of ruin, or salvation therefrom through the clemency of their landlords.—July 16.

LEICESTERSHIRE.

This season of the year being particularly interesting, as we may now form a tolerably correct estimate of the fruits of the labours of the husbandman from the forward state of the crops, I send you the following observations which strike me as applicable to this county. That of wheat first claims our attention as being the most important to the welfare of the great portion of the people. The crops of this grain are exceedingly various, according to the different qualities of the soil, and the period when the seed was put into the ground

As far as my observation extends, and from all the information I can collect, the crops are light, and a much less bulk of straw is expected than in average seasons. I have not yet seen a field of wheat which has been laid, and this is a proof that on the best soils the crop is not heavy, but on second rate and inferior they are very thin and much below an average, and some which were sown during the rains late in the autumn do not promise more than half a crop. The late showery weather has been peculiarly favourable to the rapid growth of the spring sown wheats, they have gone well into ear, though generally small, excepting on some of the best land where the yield will be very fair, while others only promise two-thirds, and those on inferior soils half a crop. I cannot say that the colour is generally good, as many fields look too dark, and the flag of a rusty hue. With very few exceptions the spring corn promises an abundant crop; both oats, barley, and especially beans, are looking well; and of the latter I have not seen any that do not surpass, both as to length of straw and quantity of pods, the crops for several years past. These cheering prospects in regard to the spring corn, I hope will, in some degree, compensate for the deficiency in wheat. Should the present cold and cloudy weather continue the harvest will not be so forward as was expected; very little will be ready for the scythe or sickle under a fortnight, and we cannot calculate upon much being cut before the middle of next month. Mowing grass has not been found so heavy as was expected at one period, the cold weather has not been favourable for its rapid growth, and many meadows have fallen light. The crops of clover and rye-grass vary much, but, upon the whole, approach an average. I cannot but allude particularly to the *Italian* ryegrass which I have grown for the last five years with the best success. I have stacked the produce of twenty acres of it and cow-grass this season, sown on wheat, and the bulk has been very great on strong clay land; the average length of the *Italian* grass is four feet, but many stems measured five, and the seed portion of them very long and full. From these two grasses, on cold strong soils, I consider I get nearly a load to the acre more than I could of the common rye-grass and red clover. The rapid growth of the eddish is astonishing, I stocked fifteen acres with one hundred sheep which

I am feeding for the butcher, as soon as the ground was cleared, and that within a fortnight from the commencement of mowing. I can well attest the fact mentioned by Dr. Buckland at the meeting of the Royal Agricultural Society at Cambridge, that the sheep will eat down to the ground this grass before they will taste the clover or other grasses growing with it. Haymaking has proceeded slowly, and about half may be secured, but with different degrees of success, and I fear much is put together in that state which will cause it come out very inferior fodder. With the exception of the 13th 14th and 15th inst. we have not had three consecutive days of bright or fair weather since the commencement of the hay-harvest. The turnips have a most favourable appearance and a prospect of an abundant crop. The plants have in no instance that I know of been attacked by the fly; they came up quick, but from the cold weather have grown slowly, and on weak sandy soils look rather sickly, still those which are hoed are going on well. Potatoes and mangel wurzel are growing rapidly, and a fair crop may be expected of these useful roots. The pastures are not good; the graziers complain of the weather being too cold, and the bottom grass does not spring up in any quantity. Fat beef is not very abundant, and realizes a good price, 6d. to 6½d. per lb. Mutton does not sell quite so high as a few weeks back, and 6d. may be quoted as the average of good qualities. The epidemic among cattle has ceased in a great degree, though it still exists in various parts of the County. It has been fatal only in very few cases, and has generally yielded to mild remedies.

In consequence of the depressed state of the Yorkshire and Leicester woollen trade, wool has sold much lower than last year. At the fair held at Leicester on the 4th inst. a large quantity was pitched, and nearly all of it sold at from 28s. to 31s. per tod. The season is approaching when the Leicester hosiery trade generally revives, and should it happen to be the case this year, we may anticipate better prices in a month or two; the impression at present is that wool is at the lowest, which cannot be said to be more than 28s. to 29s. I should say to the grower, be in no haste to sell at the present price, but hold your wool a little longer. I am happy to say our labourers are receiving 15s. per week beside beer, and in many cases, are earning by piecework from 20s. to 25s.—July 23d

AGRICULTURAL INTELLIGENCE, FAIRS, &c.

At MORETONHAMSTEAD FAIR, the show of bullocks was not very large, and in the early part of the morning business was dull, those having to sell asking a greater price than those intending to purchase were inclined to give. As the forenoon, however, advanced, a change in this respect took place, and some business was done, but at rather a decline in price, the fat bullocks being sold at about 10s. 6d. per score. Cows and calves also became in demand, and many were sold at from 9l. to 14l. Good oxen and steers, likewise, met with purchasers. Lean stock, however, was in very dull sale, the general complaint being the scarcity of grass. Of sheep and lambs there were more penned than has been known at preceding fairs for many years, but as in the bullock fair, in the morning there was an indisposition to business. As the day, however, advanced, a decline in price in this respect also took place, and some sales were effected—prime fat wethers fetching about 6d. per lb. Some Dartmoor wethers, in good condition, and in their wool, were exhibited, and

met a sale at from 5½d. to 6d. per lb. A few lots of lambs, of excellent quality, were likewise sold, at from 5½d. to 6d. per lb., and on the whole it may be said that a tolerably good share of business was done.

At THORVERTON FAIR, on Monday last, there was a wonderful exhibition of extraordinary fine rams, from some of the best breeders in the neighbourhood, and it was understood they were well let and sold. It was a very fully supplied fair of lambs, but a duller one was never experienced. It is thought that not above one-half that were shown, were sold, and those nearly of the best description. The quotation for sales too, having the extraordinary wide range of from 12s. to 27s. a piece. As to sheep,—butchers' sheep were not plenty, and those of the prime descriptions were sold,—the wethers at about 6d.; and ewes, from 5d. to 5½d. per lb. Store sheep were not in any great plenty, and on very dull sale, everybody being in want of keep. The quotation, however, for the business done, may be stated at from 22s. to 34s. a piece. There were a few grass

ed, but no winter fed bullocks shown, and those that were fit for the stall, were sold at about 10s. per score. There were a few heifers and calves, but presenting nothing beyond what may be termed a good description, and most of the best were sold at prices varying from 12l. to 15l. In the way of store bullocks, there was nothing calling for mention.

SHERBORNE FAIR on Monday last was but thinly supplied with stock in general, with the exception of lambs, of which there were about the average number, and met a very dull sale, horn lambs at from 12s. to 16s.; down lambs 15s. to 23s., and at those prices many returned unsold. With wethers and ewes the fair was but thinly supplied; wethers in good condition were inquired after, and sold readily at 6d. per lb., poor ones at from 25s. to 34s. per head. The bullock fair was also thinly supplied; beef sold slowly at 8s. 6d. to 10s. 6d. per score. From the shortness of hay at present on the land, and the small quantity of hay made this season, rendered it impossible to convert many of the poorer beasts into money. There were some useful horses of the cart kind offered, but a poor collection of nags, and but very few changed hands. The wool trade was in a very sluggish state, the sellers scarcely knowing what to ask, or the buyers what to offer; we understand the most money that could be realized was 13d. per lb., but 12d. was the general price offered, and we did not hear that scarcely any business was done in this article; on the whole, the fair may be said to have been an extremely dull one.

COLCHESTER FAIR.—The supply of sheep was not so large as we have witnessed, but the trade was exceedingly flat. There were about 4,500 penned, and not more than 1400 changed hands, at prices not quite so high as at Colchester market, on Saturday last, the best wethers fetching not more than 39s. to 40s. per head. The show of horses and cart colts was not so good as at St. John's Green fair, and from the high prices asked, scarcely any of good quality were sold. A few sales were effected from 33l. to 35 guineas each, and some of the secondary and ordinary descriptions were sold according to their quality; but the trade altogether was very dull. The show of lean beasts was by no means good, and as to sheep, scarcely any business was done. Indeed the dealers all acknowledged that they had not witnessed less trade for several years past.

EARL SOHAM FAIR.—This annual mart for the sale of sheep and lambs was held on Thursday last, and was numerously attended. The pens exhibited were acknowledged to be excellent in quality and condition, but business was very flat, and the sales that were effected were at a reduction of from 2s. to 3s. upon the prices of last year. But few beasts were shown.

At **OVERTON SHEEP AND LAMB FAIRS**, held on Saturday the 18th of July, the number penned exceeded that of any former year, amounting to upwards of 100,000 head. Owing to a long continuance of dry weather, dealers were shy of purchasing except at reduced prices, which varied from 27s. to 35s.; ewe lambs, from 29s. to 40s.; wethers, from 30s. to 47s. The stock was considered not so good in condition as last year. The show of rams, from Messrs. Saunders, Dowden, Twynam, Edney, and Beckingham, excited the admiration of numerous visitors; also a pen of ram lambs from Sir Thomas Baring, some of which were purchased by a gentleman from Belgium. The lambs and ewes entered for the prizes, given at this fair by the neighbouring gentry, were of the finest description, and being penned in the new fair ground set apart exclusively for that purpose, attracted a crowd of spectators. So large a collection of the choice stock of the far-famed breed of Hampshire was indeed a treat to the breeder and amateur not often to be met with.

ST. BOSWELL'S FAIR, July 18.—This extensive fair, which took place to-day, was well attended by both buyers and sellers. The following are the prices obtained:—Best bred lambs, 24s. 6d.; current 16s. to 22s.; half-bred from 16s. to 19s.; several lots were sold at from 16s. to 18s.; those three-parts-bred brought 19s. to 24s. Mr. Bryden, Glenormiston, sold

several lots of half-breds at 17s., 18s., and 20s. 6d.; Mr. Robert Ballantine, Peebles, a lot at 18s. 6d.; at these prices they were considered to be from 6d. to 1s. a-head above those obtained last year; and, as the supply was less, they were all readily sold off. There were a good number of sheep shown, but they were of a very ordinary description, consisting almost entirely of half-bred hogs, for which the current prices were 21s. to 24s., and at these rates they were well enough sold. Of wool there was a very fair supply, but the transactions were limited, and sales very dull. Half-bred hog wool, 29s. the stone of 24lbs.; current, 26s. to 28s.; Cheviot white wool, 21s. to 24s.; laid Cheviot, 13s. to 16s.; blackfaced wool (unsmear), 12s. to 14s.; blackfaced (laid), 7s. to 8s. There were a good many cattle, but few prime fat; those in good condition were sold at a shade lower than the previous Earlington fair. Of horses there were, as usual, a considerable number, which met a dull sale.

At **COLDFOURD (Colebrook) FAIR**, on the 13th inst., the fat bullocks, sheep, and lambs, met a sale at about late market quotations; but in store cattle and sheep there was little business done.

EXTRAORDINARY PROLIFIC BARLEY.—Mr. Samuel Barnes, of Westbury, has this year drilled in two acres with six pecks, and dibbled one acre with less than one peck of the grain, and most astonishing to relate, there are at this time to be seen from 100 to 150 stalks growing from one corn, and some of the ears contain from 30 to 40 corns in each ear; and last year the same gentleman grew nearly 24 sacks of grain per acre, of good quality. Its properties for malting has been tried, and found to answer well, but of course on a small scale. Mr. Barnes will be happy to show the barley, as now growing, to any gentleman desirous of seeing it.

“THE FARMERS’ AND GENERAL FIRE AND LIFE INSURANCE INSTITUTION.”—It will be seen by the report of proceedings in Parliament that a petition from the directors of this institution was presented to the House of Commons on Friday, the 24th of July, by Lord Ashley, praying a reduction of the duty on fire insurance, and the stamp on policies, when the insurance does not exceed fifty pounds. Within the last few months upwards of ninety cottages have been destroyed, and 200 families completely beggared in three villages in the West of England, namely, Allington and Fordington in Dorsetshire, and Stoke Cannon, near Exeter, in Devonshire. The furniture and working tools of these poor families were wholly destroyed, and no resource remained for them but the benevolence of private individuals. Subscriptions were set on foot, in one of which we observed the name of Lord Ashley, to a donation of £25. The stamp upon a policy for £50. is the same as for £5,000. The stamp and duty together operate as a prohibition in insurance for small amounts. But for the oppressive character of this tax, the poor creatures above-mentioned might have had their property reinstated, and the neighbouring residents been spared a heavy call upon their charity. From what we have been enabled to learn, the proposition is favourably entertained, and there is every reason to believe that the duty will be altered next session. This institution has already conferred a benefit upon the farmers by causing a reduction on the rate of insurance on *farming stock*; it will deserve well of the labourer if it should be the means of enabling him to avail himself of the protection of insurance against fire.—*London Journal*.

THE CROPS.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—I have delayed giving you a report of the forthcoming crops longer than I had intended, in order to see what effect the fly might have upon the wheat plant, and I am happy in having it in my power to communicate, as far as my observation goes, that all the early wheats which were in ear at the time we experienced the cold, dry winds, about the 16th, 17th, and 18th of June, prevented the fly committing its ravages, by depositing the egg which breeds the maggot at the time the ear makes its appearance, and which caused so much destruction the two last seasons; but I am afraid from present appearances that the wheat which is now coming into ear will be more or less affected, unless we be favoured with dry windy weather: I am also sorry to say, that where the land is cold clay, the crop is invariably thin upon the ground, the straw weak, and knuckle fallen, producing a small ear. With regard to the spring-sown wheats (and which are to a considerable extent), the crop will not, I think, in many situations, scarcely pay the seed and labour, being much smothered with weed, not only in this, but in the great corn-growing counties of England, where I have lately visited, and this is the case also with respect to a considerable portion of the spring grain; this, however, is not to be wondered at, when we bear in mind the remarkably wet season we had to contend with when preparing the land for the present crops, which, being so saturated and washed, will take the farmers at least from two to three years in manuring and getting into its former state. Upon the whole, I am afraid, we shall fall far short of an average crop of wheat, of which at this time we stand so much in need. It is the opinion of some that we shall have wheat cut, in the present month, in some of the early districts, which probably may be the case; but we shall have wheat also to cut, and not a small portion in September.

I have to thank you for the valuable information and the impartial accounts you continue to supply us with in your useful paper and *Farmer's Magazine*.—I am, sir, yours respectfully,

JOHN YATES.

*Colton, near Rugeley, July 2, 1840.**Bewdley, 7th Month, 3rd.*

During the past month the weather has been variable, frequently showery, and for several days cold with north winds. On the whole it has, I think, been favourable to most of the corn crops, excepting Wheat, which would be much benefited by warm sunshine and dry weather, and the complaints greatly increase respecting the indifferent appearance of this most important article of food. On the light soils, from what I hear, I should think there would be full an average crop, but on the strong clay soils—and on these most of the wheat is grown—there must I think be a great deficiency; indeed, it could scarcely have proved otherwise from the very unfavourable circumstances under which most of it was sown. There is also a great breadth of Spring-sown wheat, which is generally reported as looking unpromising. The heavy winds and showers which we have had during the time of blossoming, must also have proved injurious I consider. The barley is reported to be generally looking well, but should the wet weather continue which we have had the last few days, it will be likely to become much laid. Peas are looking well. Beans and oats not grown extensively. The crops of grass lighter than they were expected to prove.

I remain very respectfully,
HENRY STUBBS.

BEDFORD WOOL FAIR.

This fair was held on Monday week. The quantity of wool brought into the fair was limited, and few transactions were made previous to the dinner. A deal of business was done in the cattle fair, at a little advance in the cow and sheep line. The show of tups was very superior, and the competition was so great that the judges had rather a difficult task. Several very eminent agriculturists were on the ground, and bestowed great praise upon the Bedfordshire breeders.

THE DINNER.

At two o'clock a large company assembled at the Swan Hotel, and did ample justice to the excellent dinner provided. The chair was taken by Charles Barnett, Esq., supported by Lord Charles J. Fox Russell, G. P. Livius, Esq., Charles Short, Esq., &c. &c. Mr. Hyne acted as Vice-President.

After grace had been said by the Rev. James Beard, and the cloth removed,

The CHAIRMAN gave the toast of "The Queen;" after which the usual toasts were given; and then said he would feel obliged by any gentleman stating what wool he had sold, and thus set the example.

Mr. JOHN PURSER stated that he had sold his wool at 33s., leaving sixpence to the times. He had done this to support the wool fair, and to meet the purchasers who had made bad speculations before. The wool consisted of 300 Down ewes, 200 half-breds, and 56 Leicesters.

Mr. W. BENNETT stated that he was at Leighton Fair, and there was a large quantity of wool, 49,000 fleeces, and upwards of 40,000 were sold, but the prices were not high, and farmers went there with a disposition to sell at market prices. The silver cup was awarded to Mr. Waller, of Luton, who bought twenty-one thousand fleeces. Mr. Burraess sold the Duke of Bedford's wool at 35s.; there was a good deal sold at 31s. and 32s.; the average price was 31s.

The health of the Judges, Messrs. Manning, Sandon, and Purser.

Mr. SANDON returned thanks.

Mr. Anderson offered the Duke of Bedford's wool at 33s. to Mr. Waller; it consisted of 300 Leicester Ewes, 150 half-bred Teds, and 150 Southdown Ewes; Mr. Waller's agent offered 29s., which was accepted.

Mr. Paine offered his wool at 34s., consisting of 45 Leicester Teds, 62 half-bred, 161 fat sheep, and 191 ewes; but no purchaser, no sample being produced.

Mr. Barnett offered his wool at 31s., consisting of 76 Leicester Teds, 115 Leicester Ewes, 82 fat Leicesters, and 103 Down Ewes; 30s. offered.

Mr. Cant offered his wool, half Teds and half Ewes, and 40 half-bred ditto, and 80 fat sheep, to Mr. Waller.

Mr. Onslow, of Staughton, sold his wool at 32s., consisting of 135 half-bred Teds, 212 Leicester ditto, 134 half-bred and Down Ewes, 130 Leicester ditto, and 51 fat sheep.

After a few more toasts, the Chairman left the chair, and the company separated.

HERTFORD WOOL FAIR.

The annual wool fair was held on Wednesday. There was a large attendance of both sellers and buyers than at the fair last year; and the quantity of wool offered was very great. Very little business was transacted before dinner: both parties remaining firm. At the dinner at the Shire Hall, the chair was filled by C. G. Thornton, Esq., in the absence of Lord Salisbury, who was advertised to preside, and whose absence was occasioned by the necessity of his attending to his parliamentary duties.

The CHAIRMAN said, from information he had procured, he believed that the trade was now about to take a favourable turn. He had many years ago got 44s. for his wool; but he now offered Mr. Weston 300 fleeces, mixed, at 24s.—Mr. Weston offered 30s.

This lot was bought after the dinner by Mr. Hale at 31s.

C. PHILLIPS, Esq., then offered Mr. Weston 418 fleeces, consisting of 168 choice Down tegs, 83 Leicester tegs, &c. at 32s., but they were declined. He then offered them to Mr. John Archer, jun., a young buyer, of whom Mr. Phillips spoke in terms of high praise and confidence. Mr. Archer offered 31s., and Mr. Phillips, with a view to encourage him in every way he could, accepted the offer. Mr. Phillips subsequently submitted the wool of Abel Smith, Esq., M.P. to the buyers, who left the table to examine it. It consisted of 735 wethers and 443 Down tegs. On their return it was offered to Mr. Archer at 35s. for tegs, and 30s. for the others. Mr. John Archer offered 34s. and 28s. It was then offered to Mr. Weston, who declined, as Mr. Archer had outbid him. Mr. Archer's price was accepted.

EDWARD LEWIS, Esq., offered to Mr. Youde 400 tegs, 317 ewes, and 200 wethers, at 32s.; Mr. Youde could not afford more than 29s., which was refused.

Mr. BIGG offered Mr. Hales 440 half-bred tegs at 35s., but Mr. Hales declined. Mr. Weston offered 34s., but it was not accepted. Mr. Weston announced that he had bought Mr. Charles Taylor's wool, consisting of 600 fleeces, at 33s., and wethers at 28s. Mr. Dorrington, of Waterford, sold 200 fleeces mixed to Mr. Taitam, at 32s.; Mr. Sworder sold 700 fleeces, mixed, to Mr. Waller, of Luton, at 30s.; Mr. Wadsworth sold 200 tegs, 90 wethers, and 26 ewes, to Mr. Weston at 33s.

Mr. JOSEPH JACKSON sold 589 fleeces of teg and ewe wool to Mr. Taitam at 35s. and 30s.; and some more of Mr. Abel Smith's wool, consisting of 231 tegs and 131 Down ewes, at the same price.

Mr. LEWIS, the Secretary, said, in the first year 22,000 fleeces were offered; in the second year, 24,000; in the last year, 13,000; in the present year, 27,355. This was a proof that they were in an increasing, not decreasing state.

NORTHAMPTON WOOL FAIR was held on Saturday last. Samples of the different growers' lots containing ten fleeces, five of tegs, and five of ewes, were exhibited on the market place as usual. About a hundred persons, growers and buyers, were at the ordinary, at which C. Hillyard, Esq., President of the Northamptonshire Farming and Grazing Society, presided. After the usual toasts had gone round, and the assemblage of growers of wool had been more than doubled, the chairman entered on the business of the day, observing that as it could not be doubted that the woollen trade was in a distressed state, he thought it would be prudent of the growers, who wished at that time to sell, to give way a little in the prices asked before dinner; but as neither the growers or buyers seemed willing to meet half way in the prices asked and offered, about four lots only were disposed of. The Chairman sold his, which contained very nearly half tegs, all Leicesters, at 29s. 6d. per tod. Mr. Rogers of Cucknoe, which had had three or four years ago one cross with the Downs, at 31s. Mr. Kimbell's, of Earl's Barton, a very superior lot, half bred between Down and Leicester, at 33s. per tod.

ILSLEY WOOL FAIR.—There were about 300 packs of wool brought for sale; it was well attended by buyers, but business progressed rather heavily, and many lots were unsold at 4 o'clock. Ewe fleeces sold at 29s. to 30s. per tod; regular flocks, 31s. to 32s.; and teg fleeces at 35s. to 36s. per tod. The silver cup for the best 100 teg fleeces was awarded to Mr. Wm. Fidler of Boxford. About 250 sat down to an excellent cold collation, — Villebois, Esq., in the Chair, supported by the Marquis of Downshire, — Wroughton, Esq., &c. &c.

LEICESTER WOOL FAIR.—About 4000 tods were pitched, a great falling off from last year; trade dull here, as well as in Yorkshire.

REVIEW OF THE CORN TRADE DURING THE MONTH OF JULY.

In our last two reviews of the state and prospects of the corn trade, we alluded very particularly to the possibility, if not actually the probability, of the admission of foreign grown wheat into our markets of consumption on the payment of duties much more moderate than those chargeable at the forementioned periods, and circumstances have since then occurred, which render this supposition even more probable than it then was. As is usual at this season of the year, the value of all descriptions of grain is regulated by the state of the weather, and from the middle of June till towards the close of last month, this principle has had an unusually open field for action. For a period of four or five weeks, the days, and particularly the nights, were colder than is consistent with an early harvest time, and from this circumstance the ripening of wheat, in particular, has been in some degree retarded. The holders of foreign bonded grain, and the importers of foreign wheats on speculation, were not idle during the continuance of this partially unfavourable state of the weather, for after all, should we have a dry season hereafter for gathering the fruits of the earth, it is not of the slightest consequence. Rumours of every description unfavourable to the best interests of the community—we mean *thereby a good crop*—were put into circulation, and the Chronicle and the Times journals assisted in their promulgation. To make a powerful impression, however, the reports made respecting the

state of the wheat crop should, at all events, have had some degree of consistency with each other. Whilst one complained of too much moisture having injured the winter wheats, another relied on the want of rain as the certain forerunner of a deficient crop. Since our last publication the great county of Kent it seems has been afflicted with this latter evil, and many are the unfavourable predictions consequent on this complaint. We however strongly suspect that the injury effected by this cause, if any be actually done, cannot be of any material importance, and the delay which has already taken place in the commencement of the reaping season, is not of the slightest consequence should the weather hereafter be dry and favourable. The fluctuations in the value of wheat during the last month were not extensive, notwithstanding the many unfavourable rumours which were circulated respecting the state of the growing crops, for it certainly has not exceeded at any time from 2s. to 3s. per quarter on the finest samples. The differences however in the average prices from the various districts, by which the duties payable on foreign wheat, when entered for home consumption, are regulated, have been immense. The average price of wheat from various quarters in Lincolnshire is little less than 25s. per quarter cheaper than the London average for the same week. It is nearly impossible that quality alone could have produced this effect, and we can only

attribute it to a system of management which too frequently is resorted to, when it is an object of importance to prevent a decline in, or to assist in the reduction of the duties payable on the importation of foreign grain for home use. In the present case it can scarcely be doubted that great efforts have already been made, and still are making, to reduce the duty now payable on foreign wheat in particular; and at this season of the year, when the supplies of British wheat are usually small, it does not require much capital to give a fallacious tone to the wheat trade, and to render the supplies in the leading markets apparently less than the consumption. By a few well managed purchases on speculation, the stands are rapidly cleared, and the millers are occasionally deprived, until the next market day, of that quantity which is necessary to their usual consumption. Fears and surmises soon, and very naturally, succeed this managed deficiency in the supply, and rumours unfavourable to the general appearances in the fields, are the certain consequence. It works well in the mean time for the proprietors of bonded wheat and for its importers, by causing an improvement in the value of this description of grain, on the chance of a reduction in the duty. Whether such an attempt has latterly been made, it is not for us to say, but we may perhaps be permitted to give an opinion on a subject so very interesting to all readers of the Farmer's Magazine as is the state of the coming crop of wheat. Before the close of last year, the wheat seed time was certainly not so favourable as could have been wished, and it may be that in some few instances the winter wheats are apparently thin on the ground; but this may not cause, where it does exist, any material deficiency in quantity, though it may be the means of producing excellent quality. Any complaints, however, which might be made on this subject at the close of last year, must have been most abundantly removed since the commencement of the present one, for the season for spring operations could not have been more favourable, and the crops of every description have not received one solitary check during its progress. The January planted wheats are quite equal in appearance to that of any previous season, and the spring sown wheats seem at all events to be luxuriant. Since the turn of the year it is utterly impossible that any damage could have been done to the growing crops, unless it has had its origin in the very favourable state of the weather, and the injury done to the winter wheats previous to January last cannot have been to any extent; indeed, we doubt much whether the reported injury exists any where, unless it be in the imaginations of the interested in the beneficial effects to themselves of a bad crop. The weather during a part of last month certainly was not so very propitious as it had been previously, but the only unfavourable effect which it has produced has been a delay of at most fourteen days in the commencement of the reaping season, which at this early period is not of the slightest consequence. A wet harvest time alone now can be attended by injurious consequences, and we can see no reason why such a calamity should be anticipated; indeed, the chances are numerous on the opposite side. To the holders and importers of foreign wheats, the reduction in the present rates of import duty is of vast importance, and should this object be by any other means effected than by a damaged crop, it cannot in any material manner now be hurtful to the agricultural interest of the United Kingdom. A large quantity of foreign wheat, if admitted for home consump-

tion, will liberate the British capital now abstracted from home improvements, in its importation, and this quantity will, to a certain extent, at all events, supply the deficiency now existing in the farmer's stocks of British grown wheats. The liberation of this quantity of capital will tend to increase the quantity of productive labour amongst the industrious classes of British society, and will enable them to increase their means of payment, and consequently, their consumption of agricultural produce, and of home manufactured goods. Abstractedly in itself a great evil, as an entirely free trade in corn must from necessity generally be, still to put that money again into circulation, which may be locked up by speculations in foreign grain, is certainly the most favourable plan for rectifying some of the bad consequences resulting from operations so entirely anti-national; and therefore to admit the foreign wheat already purchased into home consumption cannot be so injurious, even to the interest of the British Agriculturist, as the abstraction of the money embarked in it from circulation must be. A large quantity of all descriptions of foreign grain will be imported before the close of the present year, and the deficiency in the quality generally, and also partly in the quantity of the two last crops, will no doubt render necessary the consumption of a good deal of foreign grain, even admitting as we do in every respect, that the coming crop be an abundant one, both in quantity and quality. The want of six months' consumption of British grain, which ought at this period of the year to be in the possession either of the farmers themselves, or of the corn merchants, must be supplied before the corn trade can be again placed in a sound and healthy condition, and that can now only be done out of the surplus quantity of the coming crop. Although, therefore, our home agricultural interest may for a time be inconvenienced by the admission of foreign grain into competition in our own markets with their property, still eventually the British grower will be benefitted by this circumstance, in as far as it will enable him to replace into his stores that quantity of his own crop, which at the close of every corn season it is for his interest, as well as that of the public in general, that he should have in his possession. On payment of the present duties on foreign grain, or even of lower ones, therefore, no great public injury can be done by the admission into home consumption of even a large quantity of foreign grain, for in most cases a great proportion of it is already paid for, and its consumption now is almost the only way by which the capital embarked in it can be again brought into circulation, and rendered useful in the productive employment generally of the people. A material reduction in the present rates of duties however would be almost as great a general calamity as a bad harvest itself would be, for it would place the empire nearly in the same very unfavourable position, as a free foreign corn trade would do. It would cause an immense influx into the country of foreign grain and pulse of every description, and a great abstraction of the circulating medium would be the necessary consequence. The money market even already has been rendered feverish by the unfavourable rumours, which were put in motion during the greater part of last month respecting the state of the growing crops. A demand for foreign bills of exchange was created by the importers of foreign grain, and as our exports to Europe of British manufactures, and of goods of every description, did not at the time amount in value to the sum required for the purchase of foreign corn, the rates of the foreign exchanges became less favourable to England; and a repetition of the

same circumstances would soon cause a foreign demand for silver and gold, would render money again scarce, and a reduction in the value of every thing, the wages of labour included, would be the unfortunate result. Under no circumstances can wheat be cheap during the remainder of this year, but still duties much under the present rates would be attended by much mischief, and would in a very material manner injure the best interests of all the industrious classes of society. To the agricultural interest any importations of grain from foreign nations, which can occur during the remainder of this season, cannot be of much consequence, for, as we have already stated, it will enable the farmers and corn merchants to purchase and to hold that quantity of British grown grain, which is so necessary to the health and soundness of the British corn trade; but to the mercantile and manufacturing classes of society, any large importation of foreign grain at nominal duties even, would be in every way injurious. It would render money extremely scarce, and consequently extremely dear. It would for a time put a limit to all descriptions of improvements at home, and of speculative operations, and it would thus place many thousands of families entirely out of employment. Even should this state of things reduce the value of provisions by one-half, it would not be of the slightest advantage to those engaged in commercial and manufacturing labours, for the wages of labour would be subjected to a correspondent reduction, and, what is worse still, productive employment, that great property of the industrious, would be itself materially reduced by that falling away in the home consumption of all descriptions of manufactured goods, which the dearth and scarcity of money would occasion. To prevent scenes of this description, and occurrences so very fatal to the best interests of the community, is as much the object of the corn laws, as the protection of agriculture, for cultivated fields will produce, even should commerce and trade decay. Agricultural improvements benefit the human race for ages, but the labours of commerce and manufactures are ephemeral. They depend for existence on the breath of fancy, and they decay when they become no longer fashionable. Still the corn laws are in every way of the greatest utility to these classes; indeed, they are absolutely necessary to their prosperity. They are the means of retaining within the United Kingdom those stores of wealth, out of which originate productive employment in the greatest abundance, and which consequently cause correspondent rates of wages. During the last two corn seasons not less than ten millions sterling, in specie, have been remitted for grain alone to foreign nations, which sum for many years cannot return to this country, and is consequently lost to the wealth of the empire. Had the weather not been so very unfavourable to farming operations as it was during the years 1838 and 1839, the present circulating medium would have been increased by these ten millions sterling; they would have been expended in the purchase of provisions produced at home, and would now, in some department of industry or other, have been increasing the quantity of productive labour at home, and enhancing the rates of wages paid for it. The eyes of the artisans and operatives of all descriptions are now wide open to the advantages which they reap from detaining our capital and wealth within the British empire; they see no good reason why they should be called on to give employment to foreign agricultural labourers, from whom they receive no adequate return, in preference to their fellow subjects, the agricultural

labourers at home, who expend all they gain in their native country, and whose consumption of manufactured goods is by far the most valuable department of the manufacturer's industry. A few short-sighted master manufacturers fancy that the export trade of the country may be materially increased by the exchange of our manufactures with foreigners for their grain. The operatives, however, are widely awake to their own interests on this subject. To induce foreigners to consume British manufactured goods, we must first be able to undersell their manufacturers in their own market; and this can only be accomplished by an immense reduction in the present rates of wages at home. Hence the cry originates for an unrestricted freedom in the corn trade; hence arise what some are pleased to call the benefits of reciprocity in commerce. Dearness and cheapness, however, depend entirely on circumstances. Wheat is dearer in Poland at 10s. or 15s. per qr. than it is at 60s. per qr. in England, because the wages of labour in Poland are not sufficiently high to enable the great body of the people there to consume their own wheat, even at 10s. per qr. This price in fact is too dear for their means; whilst in England the wages of labour render wheat cheap even at 60s. per quarter. The value of the necessaries of life, therefore, must always be regulated by the means of the consumers, and times will be bad indeed in the United Kingdom, should the wages of labour and the value of provisions ever be placed here on a level with those obtained in the corn districts amongst foreign nations. That our export trade has much increased under the existing corn laws during the last ten years, is abundantly proved by public documents. For the year ending in March, 1830, the official value of our exports was rather more than thirty-five millions sterling, whilst during the year ending in March, 1840, it had been increased to the enormous sum of upwards of fifty-two millions sterling: during the same period the home consumption has been nearly doubled. This favourable improvement in the commercial and manufacturing relations has chiefly originated in the sound and healthy condition of the agricultural interest, established on the improvement in the corn laws now effectually in operation during the last ten years. In a state of society so very artificial as ours is, there unfortunately must be many instances of distress, as well amongst individuals as in various branches of industry; but these generally arise from causes which eventually cure themselves, and cannot be, under present circumstances, of long duration, for the continued advance in the science of agriculture annually adds to the value of all descriptions of goods either exported or consumed at home. As geology and chemistry become better known amongst the cultivators of the soil, the labours in the fields must proportionally be increased in importance, scattering, as they soon must do, plenty over a smiling land, and sowing the seeds of benevolent feelings amongst all classes of society within the United Kingdom. The salutary protection which the corn laws extend to agriculture, and the equally salutary protection which other laws afford to every department of industry, have been attended by consequences of much importance already, but the extent of the benefits to be yet reaped from these protective laws is at present beyond all calculation. To cast the eye over England, even at the present time, and to survey the progress already made in agricultural pursuits, calls up the most pleasing reflections in the mind, but not many years can now pass, under the same progressive system, till the entire face of the country assume all the beauties of an extended garden. Then com-

merce and manufactures must flourish in proportion, and keep pace with the prosperity of the agricultural interest. Employment of every description will then be rendered, in the real meaning of the word, productive; and the wages of labour, that only true property after all, will be fully equal to supply the wants and to increase the comforts of the industriously disposed portion of the community. A good harvest season therefore at present is really of more than usual importance, and yearly, must it become more so; for a great portion of our future improvement is founded on retaining the money within the empire, and in expending it amongst the artisans and labourers of all denominations at home; for the wealth of nations can never be increased by employing the inhabitants of foreign nations in the production of any article whatever which can be either manufactured or grown at home. Only the importation of those articles, to the production of which our climate or our habits are not genial, can be attended by national advantages; and to encourage the introduction of any thing from foreign nations, at the expense and to the detriment of agriculture, must be injurious in its consequences to every class in our society. As yet we entertain sanguine hopes that no injury of much consequence, beyond the procrastination of the reaping season, which the state of the weather has latterly occasioned, has yet been done to the crop. Sunshine, genial warmth, and a dry harvest season, will soon, we are persuaded, fill the farmers' stack-yards, and the corn-merchant's granaries, with the produce of an average and good crop of all the necessaries, and of many of the luxuries of life; and then the mercantile and trading interests will find an increased consumption and good payment at home for numerous articles which they manufacture and produce. This much-to-be-wished-for result of the coming crop, should our views prove correct, will strengthen the arch of British society, and render all its links healthy and prosperous. A bad harvest season, on the contrary, must be attended by the most disastrous results to the whole community. The only well-founded complaint respecting the thinness of the wheats sown during the last autumn, may receive a remedy, we trust, in the superior growth and quality of those planted since the beginning of January last; for at all events the spring-sown wheats never had a more favourable season than the present one has been, in as far as it has yet progressed. The experiment has now been made, and the result will show the importance of the improvements already made in agricultural pursuits, for it may fairly be anticipated, from the present appearances in the fields, that the spring wheat crop will be much superior to that of former years, both in quality and in quantity, should the season for reaping and securing it prove only a propitious one.

During the last month the barley markets throughout the country have been in some measure supplied with barleys of foreign growth. The heavy duties imposed on the manufacturers of this article place an effectual bar to its extended cultivation, and whenever any failure occurs in its production that deficiency must, from necessity, be imported from foreign countries, and paid for chiefly in the precious metals. The time was when the exportation of long malt to Holland was an extensive and valuable trade to the maltsters, and, consequently, to the barley growers, but the law has long since deprived them of those advantages. The malt duty, we are persuaded, may be collected with equal security to the treasury and at much less expense to the public, than it is by the present system. The duty should be at once charged

on the raw barley, and the maltster should be permitted to manufacture his malt in that manner which he may think most suitable to the purposes for which it is intended. The excise officer at present prevents even experiments being made in the manufacture of this highly useful and important article, and thus stands in the way of various improvements, which otherwise might be effected in its production. The weight of the duty itself is another almost immeasurable obstacle to the consumption of malt, which it confines considerably under six millions of quarters, a quantity which would be doubled was this vexatious tax even slightly reduced under its present rate. The smallest power of calculation is only necessary to shew that thirty millions of British subjects would consume upwards of twelve millions of quarters of malt if their means could afford to pay for the expense. The production itself of this additional quantity of barley would furnish wealth far more than adequate to supply these means, and a duty of 10s. per quarter would make the revenue larger than 20s. per quarter can make it under the existing system. The consumption of British made spirits is also considerably lessened by the exorbitant duties imposed on their manufacture in England, and the use of foreign smuggled spirits is encouraged by the same cause. England, with sixteen millions of people, consumes only about nine millions and a half of gallons of home-made spirits, and the remaining half of her consumption must therefore be manufactured abroad, and imported into this country, without the payment of any duty whatever. To reduce the English duty to a level with that charged in Scotland would entirely suppress this illicit system of trading, would be a benefit to our barley growers, would materially improve the morals of a portion of the community, and, what the Chancellor of the Exchequer may consider the best of all, would considerably increase the revenue itself. Although during the whole of last month the supplies of British grown barley were unusually small, still the large foreign arrivals did more than make good any existing deficiency, and a decline of about 2s. per qr. was the necessary consequence, which has raised the duty levied on its importation from foreign states to 9s. 4d. per quarter. This circumstance must—for a time, at all events—place a limit to large arrivals of it from abroad; and it is to be hoped that a luxuriant crop at home will soon put an entire stop to this department of the corn trade, for we find no complaints whatever in circulation against the present appearance of the barley crop: on the contrary, it is almost universally favourably spoken of. In the fine barley lands in Suffolk and Norfolk, a little more rain will do much good, and render the produce even more valuable than it is at present expected to be, favourable as these expectations undoubtedly now are; but as we have already, and frequently stated previously, the collection of nearly twelve millions sterling of revenue from each barley crop, does not encourage the extension of the production of this most valuable article, and is deeply injurious to the agricultural interest, and to the great body of the people. Excessive taxation is not more injurious to the community than it is to the exchequer itself, for its operations are on every occasion prejudicial to the treasury, for the benefit of which alone they were imposed. Moderate rates of duty, on the contrary, generally exceed the calculation of the amount to be raised from them, and this would be the result of a material reduction in the existing rates of the public charges on malt generally, and on the home-made spirit duty levied in England.

In all the great markets of consumption, the supplies of oats from Great Britain and from Ireland, since our last report, have not been equal to the demand, and it has been requisite to enter for home consumption a considerable quantity of foreign oats to fill up the deficiency. Some low or other, oats are better protected from foreign importation than any other description of grain, and the treasury has reaped some advantages from the duties collected on the present occasion. The last crop of oats, particularly in Ireland, was extremely short in quantity, and equally inferior in quality. The consequence has been a falling off in the quantity imported from the sister Ireland, but this has been sufficiently made good by oats of foreign growth, to prevent any exorbitant enhancement of their value. The last crop now is drawing to its close, and there will not be the usual quantity of old oats in the country, when the new crop is brought into the market for consumption. This may render an additional importation still necessary from abroad, but still there is little chance of prices being otherwise than moderate. The appearance in the fields at the present time indicates a most abundant crop of this article, and in Ireland it is in a particular degree luxuriant. In due season, therefore, abundance will be forwarded from that country to all our markets, and another argument will thus be furnished of the vast importance of the corn laws to every class of society in the United Kingdom. It is through the protection of these laws that agricultural improvements make such rapid progress in Ireland, where tillage may with great truth be described as only in a state of infancy. In a few years, however, with the patronage of the British markets, and with that degree of preference which the corn laws extend to Irish oats in them, over those of foreign growth, the increase in the amount of agricultural products of every description will render supplies from foreign nations and communities entirely unnecessary, and keep the value of all the necessities of life within moderate bounds, and in every respect accommodating itself to the wages of productive labour. Then indeed our master manufacturers, with every prospect of success, may endeavour to compete, in all the markets on the continent, with foreign manufacturers, and they may increase their commercial operations abroad by this most legitimate source of business. But agricultural improvement, particularly in Ireland, must be the foundation stone on which any addition to commercial and manufacturing prosperity must rest itself, for it can never flourish on any other principle; on the contrary, every check which agriculture receives from the elements, or from any other cause, is more severely felt by the trading interest than by the tillers of the fields themselves. The importation of foreign grain during the last two years, by rendering money scarce, and consequently dear, has clearly demonstrated this fact.

With beans the markets generally have been but moderately supplied, and very few samples of peas now appear on sale. Both of these articles continue to command high prices, and as the appearances in fields of both are not so very favourable as could be desired, an opinion is entertained that higher prices may yet be obtained for them within a week or two. The crop, however, may yet disappoint all their predictions respecting its inferiority, for the July rain, at all events, cannot have done any injury to these articles, but its effects ought to have been the reverse, until the period for ripening them arrived.

The potato crop has still a luxuriant appearance, and should it be gathered only in good condition, it

must have a wonderful influence in supplying the predicted deficiencies in the wheat and pulse crops, if any actually exist; but dry and warm weather, during the next month and the present one, will, we are satisfied, yet remove every cause of complaint, whilst a dripping harvest season, on the contrary, must be attended by very serious consequences to the community.

The information received in the course of last month from abroad respecting the state of foreign corn markets has not been of much interest to the trade in this country. All these markets are chiefly regulated by the prices in London, and consequently the transactions in none of them have been of any importance. By New York letters, dated in the first week in July, we learn that the demand for flour and wheat throughout all the corn districts in the United States remained dull, and no sales to any extent had latterly been effected. The new crop of wheat is generally favourably spoken of, although it is not supposed to be so abundant as that of the previous season was. A considerable quantity of flour, in particular, would soon after these dates be forwarded to England, which had been purchased at prices so moderate, that the speculators in it would not lose any money after the payment of our present rates of duty. In the early part of last month appearances here had induced merchants to transmit to America orders for more extensive purchases, and the quantity therefore which may be shipped from thence to this country during next autumn will probably be large. The complaints against our corn duties continued very naturally to be numerous amongst the American agricultural and shipping interests, for the employment of their agricultural labourers in the production of wheat for British consumption in preference to our present system of employing our own, was to a certain degree hurtful to agriculture and to trade in the United States, and consequently the removal of all restrictions in the corn trade continued to be ardently desired amongst our transatlantic brethren.

From the Mediterranean and Black Seas the letters received are in due course of post from the various corn markets in those extensive districts, and in all of them we find that considerable purchases of wheat had been made for British account, as it was supposed, at prices which would sink money, if sold here at our present currency. The excitement which the unfavourable reports circulated latterly respecting the state of our wheat crop must still cause these purchases to be increased, and considerable quantities of these descriptions of wheats may be consequently expected during the remainder of this, and the beginning of the next year.

From the Baltic, and from all the corn markets without the Baltic Sea, the arrivals of wheat already have been large, and will be much larger if the general expectations of a considerable reduction in our rates of duty be by the event confirmed. These wheats have been purchased at prices so moderate that they must be leave a fair profit to those who have been engaged in the speculation. Considerable shipments from all these ports are still on their passage, and as long as the navigation remains open, the supply of wheat from the north of Europe will be increasing in all our markets. This state of the foreign corn trade has already caused not a little nervous feeling amongst foreign bankers here, and amongst the dealers in the sale and purchase of foreign bills of exchange. They anticipate a demand for the precious metals, and its necessary consequence, a scarcity of money, and an increase in the present scale of interest charged on the loan

of it. Already, indeed, the rates of the foreign exchanges are more unfavourable to this country than they were a month ago, and low corn duties, which a deficient crop must occasion, will greatly increase this evil, and do equal mischief with an entirely free corn trade itself. Favourable harvest weather alone can avert great evils, for to it may the country be indebted for the placing of an effectual bar to the exchange of gold for foreign grain, which must be the consequence of an unpropitious harvest season.

Cloverseed, 18,817 cwts.

SEED MARKET.

JULY 27.

Owing to an inquiry lately experienced for Cloverseed in bond, the value of this article has rather advanced; the transactions have not, however, been sufficiently general to allow of quotations being given. Canaryseed was in demand to-day, at the late improvement. New Carraway brought 1s. to 2s. more than on this day week, and Rapeseed was also the turn dearer.

PRICES OF HOPS.

BOROUGH, July 27.

The accounts of the Hops generally continued as bad as ever; duty 45,000. The season has now so far advanced, and the weather has been so unkindly, that the chances of recovery are diminished daily. Our report from Canterbury states that the bad grounds are worse, and the good becoming bad. Market very brisk, and prices continuing to look up.

LIVERPOOL, July 25.

SCOTCH.—The report of the results of the different fairs in the north have now reached us, and have had an unfavourable effect, as there seems to have been little doing, and that at fully lower rates. The first cargo of new Highland laid wool arrived in port this day, and been offered at our highest quotations, but without a purchaser. We seldom have remembered things remain so long dull, and without any prospect of improvement. In Cheviots and cross wool there is nothing doing, but continue our quotations as before.

FOREIGN.—Very little business was effected by private contract this week, but the public auction of yesterday was considered to have passed off in a tolerably favourable manner. All the New South Wales new crop brought fair prices; the condition and quality were not so good as those offered in March last, and we quote a decline on the rates then realized of 2d. per lb. on clothing, and 3d. per lb. on Combing Wool. The Spanish Germanized Odessa and Portugal were 3d. per lb. cheaper, and the East India brought full prices. Sold by Auction.—934 bales Australian and Tasmanian Wools, viz.:—Prime Combing, none; Fair Combing, 1s. 6d. to 1s. 8d.; Low Combing 1s. 5d. to 1s. 6d.; Fine Clothing, none; Fair Clothing, 1s. 5½d. to 1s. 7½d.; Low Clothing, 1s. 4d. to 1s. 5d.; Lambs, 1s. 5d. to 1s. 8½d.; Scoured, 1s. 4d. to 2s.; Skin, 11d. to 1s. 3d.; Locks and unwashed, 9½d. to 1s. 1d. Spanish:—184 bales R., 16d. to 19½d.; F. 11d. to 16d.; S., 12½d. to 14½d.; A; 1s. 1½d. to 1s. 3½d.; Portugal, 137 bales R., 13d. to 13½d.; F., 10d. to 11d.; S., 10d. to 10½d.; A., 11d. to 11½d.; Odessa, 134 bales (Germanised), 1s. 4½d. to 1s. 6d.; Austrian, 177 bales, 1s. to 1s. 1½d.; East India, 182 bales white, 8½d. to 8½d.; yellow, 8½d. to 7½d.; grey, 3½d. to 4½d.; black, 4½d. to 5d.; Smyrna, 145 bales (withdrawn); Mohair, 37 bales, 1s. 1d.; Sundry, 89 bales—Total, 2,019.

FOREIGN.

JULY 27.—Nearly 8,000 packages of Colonial and Foreign Wools are announced for sale by auction at Garraways, commencing on Wednesday next, and continuing for about ten days. By private contract exceedingly little is doing, while the imports are limited.

MANURES.

Subjoined are the present prices of several sorts of manure:—

Bone-dust, 21s. per qr. of 8 bushels.
Half-inch ditto, 20s. per qr. do.
Rape-dust, 6l. 15s. per ton.
Rags, 4l. to 4l. 10s. per ton.
Graves, 5l. to 5l. 10s. per ton.
Gypsum, 38s. per ton.
Salt, 2l. 5s. dirty, 2l. 15s. clean, per ton.
Carbon, 12s. 6d. per qr.
Soap ashes, 10s. per ton.
Artificial Manure, 12s. per qr.
Poittevin's Patent Disinfected Manure, 13s. 6d. per qr.
Nitrate of Soda, per cwt.—17s. 3d. to 18s. 0d.
Nitrate of Potash or Saltpetre, 24s. to 27s. per cwt.

The cow is a very common animal in the island of Java, and is used for milk and for work. It is a very hardy animal, and is able to withstand the heat of the climate. The cow is a very useful animal, and is a very common sight in the island of Java.

Handwritten text, likely a title or chapter heading, written vertically.

Portrait of a young Spaniel

From a drawing by J. H. P. G. 1840

THE FARMER'S MAGAZINE.

SEPTEMBER, 1840.

No. 3.—VOL. II.]

[SECOND SERIES.

PLATE I.

The engraving of the short-horned Bull, "Clementi,"—for which the premium of fifteen sovereigns was awarded to R. M. Jaques, Esq., of St. Trinians, near Richmond, Yorkshire, as the owner of the best short-horned Bull, calved since the 1st of January 1838, against ten other candidates at the second annual meeting of the Royal Agricultural Society of England, held at Cambridge on the 15th of July last,—is from a painting by Mr. W. H. Davis, of Chelsea.

Mr. Jaques has a superior herd of the improved short-horns, and has been a successful exhibitor of Clementi at the Richmondshire and Barnard Castle Agricultural Shows, on both occasions against Mr. Raine's Bull, "The Colonel," (which obtained the second premium for the best Bull of any age, and the first premium for the best two-years-old Bull at the third annual meeting of the Yorkshire Society, held at Northallerton on the 5th of August) and others. Clementi was defeated at Northallerton, a decision which seemed to create more surprise than any other given by the judges, either at Northallerton, or even at Cambridge, where some of them appeared to several, very questionable. Mr. Jaques also obtained the premium of ten sovereigns for the best short-horned yearling Heifer at Cambridge, the only two animals exhibited by him.

Clementi was bred by Mr. Parkinson, who had his dam Cassandra, by Miracle, and his sire Cossack, (1880 in the Herd book) and an extensive and select herd of the improved short-horn breed on his farms at Layfields, and South Clifton, Notts. The Bull Calf, "Collard," sold to R. M. Fox, Esq., of Fox Hall, Ireland, at the Babworth sale, for 200 guineas, being then only eight months old, is own brother to Clementi.

PLATE II.

PARTRIDGE SHOOTING—RETRIEVING.

(For Description see page 166.)

ON DRAINING LAND.

TO THE EDITOR OF THE FARMER'S MAGAZINE.

SIR,—In looking over the last number of your magazine, I observe the "queries" of "A Farmer north of the Tweed," who requests information regarding the drainage of moss land, and whether wood will suit for soles to drains in such a description of soil. As I happen to have had it in my power to gain a little information as to draining moss, beg, through the medium of your valuable journal, to suggest a few observations by way of answer to his "queries," and trust they shall in some measure prove satisfactory to him.

OLD SERIES.]

The first thing I conceive, that is necessary, before commencing to drain any portion of land, is to obtain a knowledge of the soil, and the different stratifications of which that soil or subsoil may be composed, before we can condescend upon what distance the drains ought to be from each other, and their depth, so as to secure a thorough drainage; and this principle holds equally good with regard to moss, as other soils, although our information here is much more easily acquired than in other cases, from the fact, that moss is more alike or uniform in quality, in particular situations, than any other kind of soil.

Moss, or peat soil, may be said to be of three kinds, viz., 1st. An unctuous kind of moss, of a free texture, easily imbibes water, and rich with vegetable

N

[No. 3.—VOL. XIII.

decomposition. This kind of moss is easily drained although sometimes very wet, is not difficult to cultivate, and under judicious management will render a profitable remuneration to the improver. 2nd. A fibrous quality of moss, not of so much value as the preceding, not quite so easily drained, at least not at the expense, being of a more spongy nature and having consequently a greater tendency to retain moisture, but may be turned to profitable account by being laid out into meadow, not being so well adapted as the foregoing quality for an alternate system of husbandry: and 3rd. Black retentive moss, very fine and close in its particles—generally very barren with regard to vegetable production, is much used for fuel in the south and west of Scotland, and when cut and dried, is very hard, but when wet with water after being dried in the sun, goes down like calcined lime. This kind of moss is scarcely ever so wet, at least internally, as the two first mentioned kinds, being often of an immense depth and exceedingly retentive, the water falling upon the surface remains there and collects into pools in the hollow places, where it goes off gradually by evaporation.

Not knowing to which of the above classes the moss may belong, that your querist intends draining, I have thought it proper to go into the above detail or distinction, and shall very briefly illustrate the mode of procedure I would adopt in the particular circumstances. Moss land falling under the first mentioned head, and where it exists to a considerable depth, is almost universally surrounded by rising ground, and invariably contains a considerable quantity of spring water. The other kinds of moss are to be met with in both high and low land; the first thing to be done in the operation of draining, is, to cut a proper drain or outlet to convey the water from the field or portion of ground to be drained; a deep drain should then, in my opinion, be cut round the moss, betwixt the hard or dry and wet land, to cut off the principal source of spring water, and thereby greatly facilitate and secure a thorough surface drainage. Afterwards cut the main drains or leaders in the most suitable direction for receiving the water from the collateral drains. Your querist says, he can afford to have his drains four feet deep, and I would recommend him to cut his main drains four feet deep at the lowest end or side of the moss, where they discharge themselves into the chief main, decreasing in depth as they recede from thence, so as to secure the necessary level to carry off the water. The collateral, or parallel drains, I would cut from three to three-and-a-half feet deep, and from fourteen to eighteen feet asunder, in moss falling under class *first* and *second*; and from two-and-a-half to three feet deep, and from ten to sixteen feet apart in moss, falling under class *third*, varying the distances, and being directed of course according to quality and appearances.

A large extent of moss land, part of it lying in the most uncultivated and wet state imaginable, belonging to that spirited and enterprising nobleman the Earl of Stair, in Wigtonshire, having been drained under my father's directions, and nearly according to the foregoing plan, which contains my own notions regarding peat soil, I have thus had it in my power to see that system put to the test, and it gives me pleasure to add that, in every case where acted upon, it has succeeded without a failure. A part of the mosses drained on his lordship's estates here, had wooden soles laid in the drains, which seem to suit very well where there is a constant run of water and will endure for many years; the kind of wood we have generally used, and

still use for that purpose, is beech, and the thickness of the plank or deal is never less than one inch, and I would not recommend wooden soles to be used of less thickness, but even stronger, if expense was not particularly looked to, because there is no doubt wood, in the course of time, will decay; and the more effectually the work is performed at first, the longer period will it endure, and afford the greater satisfaction. I would not, however, by any means recommend wood to be used as soles for drains in land where there is an alternation of wet and drought, because wood in such circumstances is placed in the most susceptible state for decomposition, and especially beech wood, and on which account the expectations of the improver might be very much frustrated or defeated. Soles of flat tile or slate should always be used on a hard bottom, or where there is not a great run of water or constant moisture. And I may notice here, that too much care and attention cannot be given to the draining of moss or peat soil, and also to the drains after the work is completed, as any person who has had experience in draining moss must be aware that drains, in such a situation, are more liable to go wrong than on other soils, (except, perhaps, in pure sand,) from the sitting down or compression of the moss after the water has run off,—the places containing the greatest quantity of moisture sinking most. The tail drains ought also to be kept particularly clear, and not allowed to grow up, which they do rapidly if not attended to, and thus throw the water back into the main leaders and collateral drains, and render the whole operation of no effect.

Some drainers consider it unnecessary to cut their drains in moss so deep as three or three and a half feet, but I have always found it useful to have them cut of such depth, seeing that moss land containing a tolerable portion of water shrinks and consolidates very much when the drains act properly, and when the drains are not at least three feet when opened, there is not sufficient depth when the moss is dry for improving the surface, especially where the surface is coarse or useless, and a considerable portion of it requires to be burned or rotted off; besides, a deep drain always draws better than a shallow one. An intelligent drainer, however, will always keep these considerations in view when he commences his operations.

Trusting that these observations may be of some service to "A Farmer north of the Tweed," and that you can give them a place in the next number of your magazine, I remain, Sir, your most obedient servant,

J. C.
Culhorn, 19th August.

IMPROVED CONDITION OF THE LABOURERS.—But, however explained, this and the facts mentioned above, show conclusively that the beneficial influence of the extraordinary improvements in arts and sciences made during the last sixty or seventy years has not been counterbalanced by the increase of population, and that it has not been confined to the upper and middle classes. On the contrary, these improvements have been especially beneficial to the labourers. The latter are at this moment incomparably better fed, better clothed, and better lodged, than at any former period of our history; and, in point of fact, daily enjoy, and reckon as indispensable, a great number of articles of convenience and luxury that formerly could rarely be obtained even by the richest lords. — *McCulloch's Geographical, Historical, and Statistical Dictionary, Part IV.*

ON THE KENTISH CORN-SCYTHE AND BINDING-RAKE.

By HENRY BOYS, Esq.

(From the Journal of the Royal Agricultural Society.)

TO HIS GRACE THE DUKE OF RICHMOND, PRESIDENT OF THE ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

MY LORD DUKE.—I have the honour of presenting to your Grace, as President of the Royal Agricultural Society of England, a Kentish corn-scythe, also a binding-rake, in the hope that the advantageous system of binding barley and oats may become more

known, and more generally adopted.* I enclose herewith three sketches,—1st, of the scythe with the cradle; 2nd, of the binding-rake; 3rd, showing the latter as held for the purpose of binding.

1. The Scythe with the Cradle.

2. The Binding-rake.

3. Mode of holding the Binding-rake for the purpose of binding.

In using the scythe for barley and oats, the great art is to leave a short "mane" or ridge of stubble, so that the ears of corn may rest thereon, and be kept from touching the ground, which is done by setting in and striking out, about five inches from the soil, taking care to swing the scythe well round, which will cause the corn to fall on the mane. The price per acre for mowing barley, when the acre yields four quarters, is 3s., with beer; and for oats a trifle less. A good labourer will mow two to three acres per day, as the growth may be large or otherwise. After the barley or oats have lain a sufficient time to ripen and become thoroughly dry, the binding rake is brought into operation. The bands are previously made by old men, incapable of laborious work, at the cost of 4d. per bundle of 100 bands; or by the binders themselves, in wet weather, or before the corn is dry in the morning—the preparation of which in such case, is usually included in the payment for binding. In order to secure as great length as possible, the bands are made from the barley or oats pulled up by the root, previous to the commencement of the harvest, and before the straw is perfectly ripened.

It is generally turned over, and the mould beaten off the roots with a flail, after which it is bound in sheaves, taken to the barn, and the grain slightly thrashed off, previously to making the bands.

The labourer takes the rake with both hands, as shown in the sketch (3), he proceeds to collect the corn, walking backwards, or rather sideways, his face towards the head of the rake, and the leg next thereto, keeping the straw within the rake as he steps along. As the rake fills, he lifts what he has collected on the unraked corn, until he has sufficient for a sheaf: he then throws the rake down with the teeth upwards, and binds the sheaf, taking hold of each end of the band—one in each hand—enclosing within it the corn so collected together, and thrusting his knee into the centre of the sheaf, in order to press it as closely as possible for binding tightly. While he is doing this, a boy, who can deliver bands to seven men, lays one on the handle of

* Mr. Boys having presented to the Society a set of the reaping implements referred to in this paper, they have been deposited in the rooms of the Society for the inspection of the Members.

the rake, and the man places his hand, which is next the handle of the rake, on the band, changing it, accordingly, as the row of corn to be bound may lie for him to work with the right or left hand before.

The price for binding is the same as for mowing, and a man will bind as much in a day as he will mow. Towards the evening the sheaves are collected and laid together in tens, by placing four on the ground, the ears or corn end inwards, three across them, taking care to put the corn end of the middle one in an opposite direction to the two others; two more are placed on these, and the tenth is laid on the top of all, which secures the whole from rain: the ears or corn ends, of the two sheaves of the second row, those of the third row, and that of the top sheaf, being placed in the direction which will afford the most sunny aspect. Although, I have known barley remain in the field, after being so bound and laid together for three weeks in bad weather without injury (care being taken to replace the sheaves when blown off), it is much better, and far more prudent, to carry it immediately it is bound, in which case the sheaves are merely laid together for convenience in loading, for which purpose another labourer is needed; and this universal. After the barley is so laid together, provincially termed "shocked," the field is raked with a horse-rake commencing with the part to be first carried; or, if the corn be carried as soon as bound, the operation of horse-raking is deferred till after the field is cleared.

The great advantage attending this mode of harvesting corn is undeniable; the despatch with which a

field is cleared is truly astonishing, while the labour and expense saved in carrying, stacking, unstacking, and thrashing, are sufficient recommendations for its adoption.

The corn-scythe was originally intended, and used solely for mowing barley and oats, but latterly a very large proportion of the wheat on poor land in East Kent has been harvested by this useful implement; which labour is performed by striking the wheat against the standing corn. It is then collected by the wife, and laid on bands prepared by the children: the man binds the sheaves in his way back, the woman carrying the scythe. The payment for so cutting wheat is 7s. per acre, with an allowance of four quarts of good beer per day, when the produce is about three quarters per acre, and 6d. more for every additional sack of wheat per acre. A man with his family will cut $1\frac{1}{2}$ acre per day, so that his earnings will be 10s. 6d., and there is no work to be performed during the harvest more anxiously sought for by the labourer who has a family to assist him. Frequently two men, or two men with a boy, are so employed—the men relieving each other in the use of the scythe—the boy preparing the bands. The cost of the scythe complete, which is found by the labourer, is eleven shillings; and that of the rake three shillings and sixpence.

I have the honour to be, my Lord Duke, your Grace's most obedient and very faithful servant,

Waldershare, near Dover.
April 16th, 1840.

HENRY BOYS.

A REPORT OF PRACTICAL OPERATIONS IN THE COMPARATIVE USES OF THE SICKLE AND SCYTHE IN HARVESTING WHEATS.

By JOSHUA RODWELL, Esq.

(To the Secretary of the English Agricultural Society.)

SIR,—The very great and vital importance of securing our crops in good condition, and more especially the wheat crops, not only to the farmer himself, but (in this uncertain and varied climate) to the community at large, induces me to request your permission and aid in circulating, through the medium of your journal, the results of some practical operations in the uses of the sickle and scythe in harvesting two varieties of wheat

during the harvest of 1839. The following statement applies to six fields, viz. :—

	A.	R.	P.
No. 1	21	0	0
2	30	0	0
3 and 4	33	0	0

		{ injured }		{ carted in the }	
				{ afternoon }	

In the operations of mowing (using a common scythe), the division of labour to each company of twenty men was as follows, viz.: eight men mowing, eight men tying up, one man raking (using what is commonly called a drag-rake, about 6 feet long in the head, with 25 wooden teeth), one man tying up the rakings, and two men shocking, or stooking, in the sheaves; the men changing their respective employments as they find most convenient to themselves, and thus completing their work as they proceeded.

With the desire of fairly testing these different systems in a season of so much difficulty, I gave directions to my bailiff (an unwilling witness, as will be seen, in favour of scythe-operations) to furnish me with the result of his observations in writing, which I beg herewith to subjoin.

Buckanay Farm, Nov. 1839.

"SIR,—According to your wishes I shall endeavour to give you a short account of the proofs we had last harvest of the utility of mowing wheat, instead of reaping. We may, perhaps, live several years and not see the thing again so clearly proved. Harvest was commenced by reaping on the two farms on the 6th of August by two companies, 20 men in each company, with Talavera wheat, at the Hall farm, and with golden drop at the Buckanay farm, and continued the same on the 7th and 8th. On the 9th the Hall company began mowing and tying up, which that company continued to do through the harvest; and the Buckanay company continued to reap the golden drop the rest of this week. Just now the weather proved very wet and showery, and we had very heavy rains, as will be recollected, from the 11th to the 20th; and, I well remember, I said to myself, 'Now will Mr. Rodwell find out the inconvenience of mowing wheat?' and people were calling out to me as I passed, 'what will become of your mown wheat now?' On the 21st you asked me in the morning if there would be any wheat fit to cart that day. I said I thought not, for I had examined the reaped Talavera and if that was not fit I was sure the mown was not; but I shortly after found that I was mistaken; for to my great surprise, I found the Hall company carting the mown Talavera, and to my still greater surprise found, on carefully examining it, that it was in capital condition. I examined the sheaves from one end to the other, and could find no wet or damp in them, and the bottom of the sheaf, where I expected to have found so much mischief, was quite dry. You left home on that day for two or three days, and we continued carting all that day the mown wheats, and I found to my surprise that none of the reaped Talavera wheat was fit to cart the next day; and, accordingly, occupied all the 22nd in carting the mown wheat, which was all in very good condition. On the 23rd we carted the reaped Talavera, but not in so good condition as the mown wheat, although it had stood two days longer in fine weather. The golden drop that was reaped at the same time I was obliged, now, on the 23rd, to set out singly before it was fit to cart; and after all it was not in so good condition as the mown wheat we had carted two days before.

"And now for further proofs of the superiority of the mown wheats over the reaped; I can find amongst the reaped wheats, now we are threshing them, many mouldy sheaves and sprouted kernels, but can scarcely find one in the mown wheats. There are many other proofs of the superiority of harvesting wheats with the scythe which I need not now mention, but I could say more if required.

"I am, Sir, your humble servant,

"THOMAS SCOTCHMER.

"J. Rodwell, Esq."

Hence, from the above results, it will be seen that the mown wheats were not only more secure from injury during the long-continued rains, but that they were consequently in a fit state for being safely secured from all further risk two days earlier than the reaped wheats. If this result constituted the only advantage in the use of the scythe as compared with the sickle, it would alone suffice for adopting the system of mowing and tying up in preference to reaping; but to every practical farmer it will be obvious that, with the additional quantity and value of the straw, the entire removal from the soil of all weeds and seeds (if any), and the greater facility in thus harvesting the wheat crop (the mowing being as quickly performed, and admitting, as it does, the assistance of less efficient hands than are required for reaping), and the opportunity also of gathering in your crop more effectually—these are additional benefits not to be lightly valued.

I have the honour to be, Sir,

Your obedient and faithful servant,

JOSHUA RODWELL.

Alderton, near Woodbridge, Suffolk.

March 10, 1840.

P.S.—A very interesting article on the above subject, with some practical observations, may be seen under the head of "Harvest," in the *Penny Cyclopædia*, which may be found also copied into the *Penny Magazine* for the month of August, 1839, p. 343.

THE USE OF SALT AS MANURE.

TO THE EDITOR OF THE CORNWALL GAZETTE.

St. Agnes, Aug. 5, 1840.

SIR,—In your report of the Probuss Farmers' last Monthly Meeting, several gentlemen appear to have expressed themselves in strong terms on the little utility of salt in agriculture. I would just observe that the reason of their failure is obvious; they have used it in much too large a quantity. One individual appears to have used as much as 30 bushels to an acre, whether Cornish or Imperial is not mentioned. The following extract from Parkes's *Thoughts on the Laws relating to Salt*, published in the year 1817, may be useful:—"One to six bushel: of salt to an acre of pasture land always renders such land more productive; a larger quantity will for two or three years render the land actually sterile." Common salt and the nitrate of soda act precisely in the same way; they are decomposed by the action of the atmosphere and soil, and a sufficiency of alkali is thus furnished for the supply of the plant. I have no doubt that on a relative trial of the comparative value of salt and the nitrate of soda, the latter will be excluded from our market by the lower price and equally efficient power of the former.

Your obedient Servant,

H. D.

* It is unquestionably true that, from the comparatively loose tying of mown wheats, the sheaves dry much sooner than those which are reaped and bound tight after having been grasped in the hand and laid in regular order, a greater bulk of straw is naturally obtained, and the securing the corn is expedited. This, however, can only be the case where the land is clean; otherwise, the bulk of weeds, or, where seeded, of clover, severed from the ground and gathered into the sheaves, will require more time to get in order than the reaped wheats, where the sickle strikes higher from the ground.

The expense is in favour of mowing, but I am inclined to think there is greater waste; and the rakings, from lying on the ground, being more or less trampled upon, and during a protracted harvest necessarily discoloured, would, unless kept separate, deteriorate the sample, and, as rakings, are undoubtedly of less value. —H. HANDLEY.

PARTRIDGE SHOOTING ;

RETRIEVING.

(PLATE II.)

The subject of the present embellishment is a setter acting the part of retriever, and hence we are given to suppose that the dog has fetched the bird which had been killed over him. The partridge in the mouth of the dog speaks for itself, it is the sire of the covey, the old cock, who has thus fallen a sacrifice to his paternal fondness and care of his family. There are very few sportsmen but are well aware of the extreme anxiety manifested by the old male for his family; that he, like a careful guide and pioneer, leads the way, and directs every movement; that he is for ever on the alert, watching every suspicious approach, and giving the signal accordingly; when he perceives the sportsman enter the enclosure where he and his family are feeding, or are otherwise employed, he eyes every motion, and when at length he considers his charge no longer safe in "trusting to their heels," he rises on the wing, screaming aloud the moment his pinions are in operation, thus warning the hen and his brood of the danger, and shewing them (as he thinks) the means of escape; in rising, he is conspicuous from his superior size, and in consequence frequently falls a victim to his laudable affectionate feelings. The beautiful embellishment under consideration, exhibits the sacrifice of the sire for the security of his family.

The moorcock (the red-grouse) on the approach of the sportsman runs out from the brood, and rises some yards in advance, giving the signal (by chattering) for the family to follow him; he is more anxious to take care of himself than for the safety of his charge; while the cock partridge may be said to run all risks, and devote himself for the welfare of the covey. He rises in the midst of the young birds, and thus frequently loses his life; but, being surrounded by his alarmed and fluttering family, it not unfrequently happens that several birds fall from one discharge.

Setters are almost uniformly supposed to be more giddy than pointers, and such is in general the case; because their olfactory organs are of an inferior description; if the scent be not good, they are thus rendered uncertain in approaching game, and are apt to spring it accordingly; the rising of game under such circumstances provokes them to chase, and consequently confusion and vexation must necessarily ensue. When however the setter's head has, by judicious crossing, been rendered sufficiently capacious to afford room for that expansion of the olfactory nerves (so remarkable in the Spanish pointer, and particularly in the talbot or old English bloodhound) his sense of smell must be in precise proportion; he will therefore recognise his game in a satisfactory manner to himself, and evince the requisite steadiness.

Then again a notion is entertained that the setter is able to range or beat for a longer time, and to come out more frequently than the pointer, and so he will; because pointers are not (generally speaking) sufficiently symmetrical for great speed or extraordinary powers of endurance, and particularly defective in the feet. But, let this animal be so bred that his conformation becomes calculated to impart the requisite progressive motion; let him get rid of his crooked fore legs and widely spread spongy foot, (inherited from his Spanish progenitors) and those replaced with straight limbs

and narrow hard wiry toes, and his incapacity alluded to above will entirely disappear.

From the setter being represented with the bird in his mouth, we are given to understand that he unites two characters, namely, the setter and the retriever.

To set or point birds, and bring them when killed, is too much to expect from the same dog; if excellence be the object in either attainment, he should be kept to that and that alone. When dogs are encouraged to retrieve, they are very apt to break away on the shot, setters in particular: the fall of the bird, directly in sight of the dog, is too great a temptation.

The setter will become a dog of all work; he will range the mountains for grouse, beat the enclosures for partridges, thread the thickets and the brakes in search of woodcocks; pointers will answer the two first purposes equally well, much better indeed, but they enter thickets reluctantly; because their coat is not sufficient protection, like that of the setter, against the operations of briars and thorns.

ON EATING WINTER TARES ON THE GROUND BY SHEEP.

SIR,—In reply to "A Northern's" enquiries relative to the feeding of tares with sheep, I beg to acquaint him, through the medium of your magazine, with the system I have adopted, and that very successfully, for many years past.

I have endeavoured so to arrange my crops that the same may, as near as possible, come under the four-course system, which I consider far the best.

My flock of sheep being large, I require considerable time in the months of March and April when my turnip crop is drawing to a close, and my grass land already supplied with my breeding stock; to provide for this emergency, I invariably sow my oat grattan, or stubble, with rye and tares. The rye is sown as early as possible after the field is cleared, and about the first week in September another part is sown with tares as a first sowing, and the remainder in the course of a month, as time permits.

The rye is ready to be commenced with in the latter end of March. When the whole is consumed, which is generally about the first week in May, the tares are ready for the fold.

I invariably allow my stock *plenty*, with the addition of oil cake, commencing at the rate of half a pound per head, and increasing it by degrees to 1½ lb. daily. By this system 10 acres of tares will provide ample keep for 250 sheep for a month.

The broadshare closely follows the fold, and the subsequent ploughings prepare the land for the turnip crop, which is put in as fast as the land is ready, *always in drills*.

"A Northern" will find if he pursues this plan that his sheep may be disposed of off the tares, to his own as well as the butcher's satisfaction.

I am fearful I have prolonged my remarks more than is necessary, but, if I have been the means of affording "Northern" the least information it will give me pleasure.

I am, Mr. Editor, yours, very respectfully,

A SUBSCRIBER.

Aug. 17,

AGRICULTURE.

TO THE EDITOR OF THE MARK LANE EXPRESS.

Agriculture being the principal prop of existence, the most pleasing and interesting of all the arts and sciences, the study of it ought to be pursued with a zealous, fervent desire to do it justice.

The farmer occupies one of the most honourable, praiseworthy, and noble stations under the canopy of heaven. Some may pretend to dispute this assertion, and contend that he is inferior to the physician, lawyer, and merchant; but it is nevertheless supported by good sound sense, consequently deserves to be universally acknowledged and approved.

The giddy fair, enamoured with a white hand and costly attire, scorn the practical farmer's soiled business suit; in their weakness, they imagine he cannot possibly be deemed a gentleman; by such vain notions they lead men to adopt some profession on account of the *supposed* superiority; narrow must that mind be, that can harbour such an opinion, and thoughtless the tongue that asserts it.

Far be it from me to include all women in this censure, I honour the fair sex, and heartily bear testimony to their worth; neither do I intend to charge England with folly in this respect. America contains more professional men, (as they are called) than she can support.

I am happy to find her Majesty setting a good example, by patronising the Royal Agricultural Society. In this her good sense is clearly seen; we are by it assured, that her mind is well stored, and adapted to her high station; by such conduct, she secures to herself, the affection and ready protection of her best subjects; the farmer should be upheld, and (in a great degree) be considered a nation's support. Surely he that can shine at the plough, and in other acts of husbandry, has it in his power to acquire solid information, may possess refinement of manner and a mind sufficiently cultivated to be freely admitted to good society, and is a gentleman to all intents and purposes! he would be valued and respected by all persons of judgment; it would be no degradation in their estimation, were his hand hardened by toil, and his countenance bronzed by the sun; these appearances would speak his praise, by showing that he neglected not the duties of his station. Is not such a man happy and contented? He cares not for domineering wealth, proud pedigree, or idle fashions; he steadily and actively pursues his manly occupation, never losing sight of judgment, *good breeding*, and moderation, feeling assured that such a line of conduct must sustain him, and ultimately procure approbation and exaltation; who would seek ought beyond this? Will not the cultivation of the land assist in the cultivation of the mind? Will it not purify the heart, and lay a sure foundation for a final state of happiness? Will not a man thus occupied, look forward with hope and satisfaction to that period of his life when he is called upon to pay the last tribute to his mother earth? Yes, the enlightened, honest, practical farmer, will then feel that he has in some degree performed the duties allotted to him.

I came from America, and have been selecting some superior stock to adorn that extensive country (yet in her infancy); the cattle I purchase will be distributed amongst enterprising men; men who desire to see America more on an equality with England in this respect, and who will spare neither money or exertion to produce the required improvements; those then of whom I purchase, may rest assured that their stock will pass into the hands of

men quite capable of appreciating the good qualities belonging thereto.

I beg to add that the proprietors of the "Cultivator" for the improvement of the mind and soil, wish me to introduce this work to the Farmer's notice; it is considered by its present supporters (upwards of twenty thousand subscribers) one of the best periodicals in America; the most influential families in England, I think would find it worthy of perusal.

I cannot help noticing the *superior management*, experience and knowledge of Messrs. Wm. and Joseph Hewer, of Northleach, Gloucestershire, in bringing their rams to the high state they have done. I never saw sixty sheep shown together in my life, so near the standard of perfection, the average was 17l. 16s. 10d.—the highest price 83 guineas. I am happy to say I have 14 of these to take with me, and trust they will meet with the approbation of all who see them, and be received with that welcome, the merit and perseverance their breeders deserve. I close this epistle by saying, that I hope from my heart, England and America will for ever be friends. I am, dear Sir, yours, most respectfully,

W. H. SOTNAM.

*Perch Lake Farm, Jefferson County,
York State, North America.*

N.B. The Messrs. Hewers reserved one shearling that excited the admiration of all who saw him, a more complete sheep was never shown in the world; one of the first tup-breeders in the North of England, offered one hundred and fifty guineas for him.

ON DIVERS INTERESTING AGRICULTURAL SUBJECTS.

SIR.—In page 25 in the Farmer's Magazine of July 1840, Clodpole writes about Charlock, and calls it yellow boy, and growing on stiff land, he says a good dressing of chalk is the first step. Now as Charlock abounds in chalk, this is odd and strange. As to drilling and hoeing, I agree with him, but having laid out chalk on grass land up came Lopp Grass, which resulted from the chalky ground, from whence I took it, having borne sanfoin, for several years. I agree with Clodpole about under-draining, of which much has been written in the Farmer's Magazine, since 1795, and of which I accidentally became possessed, and respecting which I may hereafter write again if you think it worth inserting. Mr. Pusey, of Pusey, in Berks, is at present making some trials of ploughs, which is already in your Magazine, and well worth attending to.

I have much to say about spreading farming knowledge from the North to the South of England, which is much wanted, and I know no better mode of doing it than through your Magazine.

About 1780, the Devon farmers never boed their turnips. At that time, I being often in Devon endeavoured to persuade them to do so, but in vain; soon after our Berkshire militia were quartered there and taught them. Now it is usually done there; but it may be 40 years before they horse-hoe them as they now do in the Northern counties, and of which the late Mr. Cobbett speaks or rather wrote after his lecturing journey there in 1834 to 5, and all derived from the late Mr. Jethro Tull, who wrote in 1737.

Sub-soil draining and trenching as now practised in the Northern counties should be spread and known in the south.

Yours &c.,
Newbury in Berks, July 7th.

W. BUDD.

ON SEA WEED.

Sea-weed, or *Fucus*, ($\phi\upsilon\kappa\omicron\varsigma$, Gr. *fuka*, Heb. a purple dye used for painting, and obtained from a sea-plant; *fucare*, Lat. to dye or paint, some of the sea-weed being used for that purpose,) is much used as a manure on lands near the sea-coast where it can be obtained. The fuci constitute an extensive order of cryptogamous plants, and all of them have a thin, glutinous, coriaceous texture or substance. The species most common are.—1. *Fucus serratus*. 2. *vesiculosus*, being the two kinds mostly used in making kelp. 3. *Fucus nodosus*. 4. *Palmatus*. 5. *Siliquosus*. 6. *Digitatus*, the strong tall plant that abounds in most places on the coast, and these are usually mixed with other species, and with the “*Ulvas* and *confervas*.” Some kinds are cooked and used as food, and the “*Fucus saccharinus*” or “*Dulse*,” is eaten in a raw or dried state. This name is given by some botanists to a much larger plant than the one generally called “*Dulse*,” being of a tawney colour, with an elliptic leaf, and without any mid-rib; the ashes have given no less than 21 ingredients:

A saccharine matter.
Mucilage in considerable quantity.
Vegetable albumen.
Green colouring matter.
Oxalate of Potash.
Malate of do.
Sulphate of do.
Do. of Soda.
Do. of Magnesia.
Muriate of Potash.
Do. of Soda.
Do. of Magnesia.
Sulphite of Soda.
Carbonate of Potash.
Do. of Soda.
Hydriodate of Potash.
Silica.
Subphosphate of Lime.
Do. of Magnesia.
Oxide of iron, probably united with phosphoric acid.
Oxalate of lime.

“*Fucus digitatus*” has the same constituents but in different proportions, the quantity of “hydriodate of potash” was smaller. The colour is usually olive, stem round, leaves plain and broad, and much divided.

“*Fucus vesiculosus*” from 100-parts dried, gave:
A brownish, red, slimy matter, fresh red extract with some sulphate and muriate of soda..... 4
A peculiar acid..... 2
Resinous fat.....
Sulphate of Soda, with some common salt..... 3.13
Sulphate of lime with much Sulphate of Magnesia, and some phosphate of lime 12.87
Traces of oxides of iron and manganese.
Membranous matter or albumen of Fuci.. 78.
Silica.....

100

“*Fucus Serratus*” has abundance of mucilage, albumen, and more carbonate of Soda, than the last species. The leaf is dichotomous and serrated, but has no air-bladders. “*Fucus siliquosus*” has abundance of albumen, and the same salts as the last analysis; stalk waved and coriaceous, much branched with little pods.

Marine plants abound with soda, and have been found to contain $\frac{1}{2}$ of a gelatinous substance similar to mucilage, and $\frac{1}{2}$ of its weight of water, but no ammonia. The ashes contain sea-salt, carbonate of soda, and carbonaceous matter, the gaseous matter was small, chiefly carbonic acid, gaseous oxide of carbon, and a little hydro-carbonate, and water of the boiled plant, has an empyreumatic and slightly sour taste. It is almost universally applied fresh on the land, as it is thrown on the beach by tides and storms; it requires no preparation as there is no woody fibre to be reduced, and it loses both bulk and quality, by fermentation and exposure. *Fucus* fermented to lose $\frac{1}{2}$ of its weight, afforded less than $\frac{1}{2}$ of mucilaginous matter, so that fermentation must destroy that substance. The effects as manure are very transient, which may be accounted for by the great quantity of water, or the elements of water it contains; it melts and dissolves on exposure without any heat being evolved, and it is supposed that the carbonic acid formed by the incipient fermentation when applied fresh, must be partly dissolved by the water set free in the same process, and thus become capable of absorption by the roots of plants. The effect of this manure is supposed to depend chiefly on this carbonic acid and the soluble mucilage it contains, which latter substances all sea weeds lose by fermentation. It is applied fresh with great success on stubbles before winter ploughing, and on leys to be ploughed for oats, and on wheat fallows in autumn, and also as a top-dressing on grass lands. The quality of farm-yard dung is prodigiously improved by it, and also of all earthy composts; in these cases, it is laid on the top before turning, and the heap is provided with a bottom layer of earth, to receive the oozings from the mixture. It may be used by laying it in the yards in thin layers with straw, and dung of most excellent quality has been produced by this method. Sea-weed has been laid fresh in drills for potatoes with much success, and without imparting any watery quality to the roots; but in other instances, that practice has been abandoned from reasons deduced from that very circumstance. During the seasons of sea-weed being cast on the sea-shore, the farmers prepare heaps of dung and soil to receive the immediate benefit, and these heaps along with the lands to which it can be applied, afford a ready application of this invaluable article. Dung for turnips is improved by it almost beyond description; moisture is imparted, the straw is decomposed, and the whole mass is reduced to a mucilaginous state, and never fails to vindicate the expectations. The fuci have been burnt and the ashes applied as a manure, but the great diminution in bulk will not encourage that mode of preparation. Experience recommends a fresh application without any exposure or delay, on strawy or earthy heaps, or on land.

Kelp is a preparation of fuci by burning, and used in making glass, now nearly superseded by the use of Barilla, which contains four times the quantity of soda, and of a purer quality. Common kelp is a mixture of soda, sea-salt, earths, and stones, and when used as a manure it is reduced to powder, by machinery or pounding, and mixed with sand or earth. The action is that of lime and potash, and being acrid and caustic, the mixture is applied at the rate of 3 or 4 cwt. on an acre, as a top-dressing on any young crops, or spread on the surface and lightly harrowed early in the spring. It costs about 3*l.* 10*s.* per ton; but the expence of preparation and the small quantity produced, 1 cwt. from 30 of weed, will not allow any extensive use of the substance.

Aug. 20.

J. D.

ACCOUNT OF THE CHARLBURY SUBSOIL-PLOUGH.

By PHILIP PUSEY, Esq., M.P., F.R. AND G.S.

(From the Journal of the Royal Agricultural Society.)

I beg to lay, very shortly, before the Society some account of an implement which I have found to answer, so far as it has been tried, as a substitute for the subsoil-plough of Mr. Smith: and, in mentioning that gentleman's name, I need scarcely say that to the individual whose talents and perseverance establish any discovery belongs the merit, while subsequent variations, if improvements they be, flow from it almost as a matter of course. It is well known that in stirring the subsoil Mr. Smith employs first a common plough to open the furrow, and next a strong iron swing-plough, without mould-board, which is the subsoil-plough that follows the common one, and stirs the ground below the furrow to the depth of 12 or 16 inches from the surface without bringing it up. But, however valuable this discovery, whether coupled or not with thorough-draining, may on some soils prove to be, as I trust it will, still an operation so conducted requires a large employment of horse-power, and consequently an expence which may not be within the means of every farmer. The common plough which opens the furrow will of course require two horses, and sometimes three; the Deanston subsoil-plough four horses at least, and I believe oftener six, if

the full depth aimed at, 16 inches, is to be reached. Indeed, in a case which comes within my own knowledge, a practical agriculturist, in calculating the expence of entering on a cold clay farm of not six hundred acres, laid the cost of subsoiling it, apart from the draining, at the very serious amount of 1300*l.* It struck me, therefore, that possibly the discovery of Mr. Smith might be carried a little further, and be brought more within ordinary means, if we could diminish the friction necessarily incurred in passing through the unstirred subsoil, by dispensing with more parts of the common plough besides the mould-board: and I determined to try whether, by combining in one plough the two hitherto used, we might not get rid of the sole itself in the underground implement; trusting to the ordinary sole above ground for preserving the balance, and so reducing the instrument below the furrow, where the friction and resistance are of course very great, to a mere cutting or stirring tool. Mr. Hart, of Wantage, accordingly constructed for me one of his own single-wheeled ploughs, made rather stout in the beam, with a strong iron socket behind, and a simple tine fitted into it; the shape of the tine being copied from those of Biddell's scarifier, but made much thinner. This back-tine can be raised or lowered in the socket at pleasure. It is placed on the off side of the beam, in order that it may work in the middle of the fresh furrow, and so act more freely than if it were placed on the near side immediately against the unstirred land.

In order to ascertain in the first place what diminution of draught had been effected, a trial was made with Mr. Cottam's draught-gauge in a field the soil and subsoil of which are a rather strong loam. The draught of the Deanston subsoil-plough, at the depth of 16 inches, was 12 cwt.; to this must be added for the leading plough which opens the furrow 2 cwt.; making the labour of the horses 14 cwt. altogether. The draught of the new plough was between 7 and 8 cwt. With regard to the effect of the new plough, it must be remembered that the gentleman to whom we owe so much on this subject very correctly states, in his evidence given before the Agricultural Committee of 1836, that there are two distinct objects in subsoil-ploughing. The first of these is to let down the surface-water into deep drains through the clefts left in the subsoil: this advantage, I hope, may be equally attained with either plough. On the other point, the thorough stirring of the subsoil and its preparation for the support of crops, there can be no doubt that the Deanston plough is more efficient than mine; still the latter does loosen the ground considerably, and may be useful, I think, in retentive gravels, while in a really stiff clay it seems doubtful whether any subsoiling lasts very

long. But I cannot speak positively, because, except in a few trials, I have only used it as yet for getting in carrots: so far, however, it has been found to answer. The ground, the subsoil of which is strong, was worked once with this plough, to the depth of 12 inches: this was done with four horses. It was afterwards gone over twice with that excellent practical instrument Biddell's scarifier, made by Messrs. Ransome; and was then, I believe, in good tilth for the purpose, to the depth which we had reached. If, however, it were desired to stir the ground more in the first ploughing, it would be easy of course to fix a spur on the back-tine, but the advantage will be attended of course with some increase in the draught. I will not only add that, if any agriculturist who has land which he thinks may be improved by subsoil-ploughing be disposed to give this implement a trial, Messrs. Ransome, Mr. Cottam, and Mr. Hart have each a pattern of it; and that, when the back-tine is removed altogether, it is a serviceable one-wheeled plough. If it be intended to break into a very stiff or stony subsoil, this should be known to the maker, that the strength of the implement may be increased.

PHILIP PUSEY.

Pusey, May 4, 1840.

ON THE PROPOSED ESTABLISHMENT OF A YORKSHIRE AGRICULTURAL SCHOOL AND MODEL FARM.

It has long been a very favourite object cherished by many of the leading members of the Yorkshire Agricultural Society, to attempt the establishment of a system of Agricultural Education; the absence of which has been very seriously felt by various important classes of society.

It has also been conceived, that, owing to the very central situation of York in reference to the County at large, as well as to the extensive agricultural district in which our Northern Metropolis is situated, no site would be more appropriate for the formation of a Yorkshire Agricultural School than this ancient city or its immediate vicinity.

The Secretary has accordingly been requested to draw up the outline of a plan professing this design. The task is by no means an easy one. In attempting very little more than a slight glance at the immense natural advantages which promise to result from a system of agricultural education, the subject would scarcely have justice done to it under the compass of a moderate volume. The Secretary must, therefore, confine himself to reducing the proposition to certain general heads of suggestion, leaving many of the details to be supplied by such of the Members as may have already turned their attention to a scheme of this kind, and reflected upon the means by which it may be the best accomplished.

Introductory to these suggestions it may be proper to state, first, the general objects sought to be obtained in an agricultural school;—secondly, the disadvantages under which various classes of society appear to labour from want of the opportunities of attaining a scientific education of this nature. These being briefly adverted to, suggestions may, in the third place, be offered, regarding the most efficient mode in which an agricultural school can be established; and lastly, the prospectus for a scheme of this kind may be submitted to the consideration of the Society.

First:—THE GENERAL OBJECTS SOUGHT TO BE OBTAINED IN AN AGRICULTURAL SCHOOL.

These are two-fold; namely, to give the masses an opportunity of acquiring a competent knowledge of agriculture in its most improved state; and, as a consequence of this education, still farther to enlarge the too limited sphere of agricultural science. To these two objects we shall slightly advert.

The first and preliminary design is to give the masses an opportunity of acquiring a competent knowledge of agriculture in its most improved state. Under this head, little or no comment is demanded. Every department of science, agriculture excepted, avails itself of the improvements of the age, because these improvements are adverted to and expatiated upon by discerning professors. If Medicine, Chemistry, or Engineering were deprived of their legitimate teachers, it would be very easy to prognosticate the state to which these noble arts would be very soon reduced. And, if we would wish to follow out the effects which have resulted from the want of competent schools of agriculture, we need not travel very far from our own boasted country. France, Switzerland, and other states have already felt and appreciated this want, and hence the flourishing seminaries of Grignon, and of Hofwyl.

The second object sought to be attained in an agri-

cultural school is, as a consequence of education, to create a young and active host of cultivators, calculated to enlarge, on legitimate principles, the too limited sphere of this science. That the knowledge and the practice of agriculture have made great advances during these forty years, is an undoubted fact; yet it is not less true, that this advance has not kept pace with the improvements which have been effected during the same period in every other leading department of national industry.

Second:—ENUMERATION OF THE VARIOUS CLASSES OF SOCIETY WHO LABOUR UNDER THE WANT OF MEANS AFFORDED BY AN AGRICULTURAL SCHOOL.

These classes may be reduced to the following: (1.) The smaller farmers; (2.) The more wealthy cultivators of the soil; (3.) Agricultural adventurers to the colonies; (4.) Capitalists intent upon introducing agricultural improvements at home; (5.) Those who are entrusted with the management of large estates, as stewards, bailiffs, factors, &c.; and lastly, (6.) Landed proprietors themselves. The disadvantages under which these classes labour, from the deficiency of a school of agriculture, we shall consider in their order:—

(1.) **OF THE SMALL FARMERS.**—Farmers are an isolated class; they are (to use a common phrase) “a home-keeping body;”—they possess neither the means of obtaining, nor the power of communicating the knowledge, which is afforded to those who live and work more in masses. The education of the son of the smaller farmer is usually confined to that which can be given by the village schoolmaster: while his means of acquiring a knowledge of agriculture is restricted to the practice of his father, or to that of his immediate neighbourhood.

(2.) **OF THE MORE WEALTHY CULTIVATORS OF THE SOIL.**—If we ascend to a more wealthy class, a “boarding school” affords the means of a more liberal education. It has the good effect of enlarging the views and of giving a taste for reading, which is utterly unknown among those below this rank of agricultural society. But if it be intended that a youth of this class should pass his life in the country as a farmer, it will be found that common schools have no connexion whatever with agriculture. Though agriculture be a science, it is not made a branch of study; no lectures are given upon agriculture, upon chemistry, botany, geology, mechanics, or the veterinary science. Yet some knowledge on all these subjects is absolutely necessary to enable an extensive farmer to cultivate his land to the full advantage. The prosecution of these studies in after life, when an individual is chained down to the practical working of a farm for a livelihood, becomes almost impossible.

(3.) **OF AGRICULTURAL ADVENTURERS TO THE COLONIES.**—The vast increase of our population, considered in reference to the extent of our colonies, renders it necessary that we should look for sources of profitable industry, to which capital may be applied, beyond the bounds of our sea-girt shore. The only field open to speculation, upon the first occupation of every colony, is agriculture. The sons of mercantile gentlemen, and of the most extensive manufacturers, are sent out to Canada, to Australia, or to New Zealand, for the purpose of investing capital in agricultural pursuits, of making money from a business of which they know nothing; dependent solely upon the honest bailiff or foreman who has been engaged to accompany them, and who is to take the management of the concern. This man is, nineteen times out of twenty, possessed of a mere local knowledge, derived from mere local practice. It

will be conceded that, if a manufacturer from Leeds were to exchange his business with a manufacturer from Manchester, both would be greatly deficient in a profitable knowledge of their reversed occupation; and yet there is not a greater difference between the fabrication of a cotton gown and a woollen coat, than exists between the profitable cultivation of a Yorkshire Wold farm, and a farm on the banks of the river Ouse.

In short, no class of persons stands in greater need of an Agricultural School, than the young men who are daily sent forth with British capital to colonize distant lands. Their professional education, in reference to the treatment of land, as modified by all possible circumstances of climate, soil and vegetation, ought to be conducted on the most comprehensive principles.

(4.) OF CAPITALISTS ABOUT TO INTRODUCE AGRICULTURAL IMPROVEMENTS ON THEIR ESTATES AT HOME.—How many estates do we see at home where large sums of money have been unprofitably expended in vain attempts to improve upon incorrect principles? How many more do we see where signal advantages might have been obtained from a more perfect knowledge of agriculture, combined with the management of woods and waters; the latter branch being totally overlooked and neglected. There can be only one remedy for such errors,—agricultural education.

(5.) OF THOSE WHO ARE ENTRUSTED WITH THE MANAGEMENT OF ESTATES,—SUCH AS STEWARDS, BAILIFFS, FACTORS, &c.—That an agricultural education, upon the most enlarged and finished basis, is necessary for this very responsible class of society, is too obvious to need any comment whatever.

(6.) OF LANDED PROPRIETORS, OR HEIRS OF LARGE ESTATES.—This, the highest class to whom a knowledge of the best manner of managing their estates, would be of the first moment, have, at present, no efficient school of instruction to which they can resort, with the exception of the University of Edinburgh. Scotland, in its public means of instruction has limited itself to the establishment of a chair of agriculture, from which an enlightened and zealous professor has long inculcated the most important principles and improvements in reference to the highly cultivated and contiguous districts of the Lothians and other places. The example is proposed to be followed by Oxford.

Third:—SUGGESTIONS ON THE MODE OF ESTABLISHING AN AGRICULTURAL SCHOOL AND MODEL FARM.

The various classes of society who labour under the want of those means, which are afforded by an agricultural education have been enumerated. That this urgent demand should have found opportunities of utterance was naturally to be expected. Several very sensible essays, pointing out the most incalculable advantages which would arise from an agricultural school in Yorkshire, have at different intervals appeared in the county journals; and, at a meeting of the Philosophical Society of York, the subject has given rise to a luminous disquisition by a Magistrate of this City, Thomas Barstow, Esq.

In the county of Kent, a similar feeling has already been incited to active exertions. On the 10th of January, 1839, a number of influential gentlemen met at Maidstone, for the purpose of promoting a public scheme of agricultural education, on which occasion a Sub-Committee was formed for the framing and maturing the scheme of a "Kent Agricultural College;" and, on the 14th of May subsequently, their plan having been submitted to a public meeting,

held at the Town Hall at Maidstone, was considered. In order to raise subscriptions for this object, an appeal has been made to the disinterested or patriotic motives of its well-wishers, as well as to the consideration of those who were inclined to promote such an undertaking under the usual prudential stipulations of interest for money advanced. Hence both free donors and subscribers were invited to assist in the undertaking.

With regard to the last mentioned promoters, who must always form the most numerous class of the two, the following remarks are suggested:

Independently of the higher or patriotic motives which exist for attempting the foundation of a Yorkshire school of agriculture, it is to be presumed, that the outlay required for an establishment so imperiously called for by the inconveniences under which several important classes of society continue to labour, would by the fees of students, *amply remunerate its contributors*. But, as opinions may at the outset vary on this question, it would be only prudent to consider an establishment of this kind as subsisting under different degrees of greater or less pecuniary support, and of making a proportionate estimate of the good which it is enabled to effect under such varying circumstances.

These different means of instruction depending on the amount of pecuniary resources, reduce themselves to four in number.

(1.) *An Agricultural school, in its most humble form, may be conducted by a single Professor, with the aid of such practical illustrations as may be derived from contiguous farms.*

In admitting the efficiency, to a certain degree, of this mode of instruction, it is scarcely necessary to premise, that without the command of a liberal amount of funds, a scheme even of this humble kind must inevitably fail. We shall, however, suppose in the first instance that a school is called into existence under a straightened condition of pecuniary resources, requiring the greatest economy possible of its funds. In such a case, nearly the whole which could be effected would be the engagement of a professor of agriculture, for whose indemnity from the usual temporary loss of an incipient undertaking, a proportionate annual sum must be reserved.

The duties of the professor would be, first, to give very full and comprehensive courses of lectures; and, secondly, to illustrate the same by *practical observations*, without which all mere oral instructions would be comparatively inert.

Now, in order to effect the latter object, it would be advisable, in reference to this minimum degree of support, to secure for a proper remuneration, the permission of some respectable farmer, that his grounds, in the mode of their cultivation, be subjected to the more enlightened and improved views of the professor. This plan would, in the interim, form an eligible substitute for a MODEL FARM, which could not be commanded without a greater increase of funds.

In addition to this aid towards practical instruction, it may likewise be hoped, that other farmers in the neighbourhood would give a general permission, that at convenient and stated periods their grounds be inspected for the sake of instruction. Ambulatory visits might thus be conducted, during which the teacher might very profitably point out to his class the various methods of cultivation in actual practice; and it is to be presumed, that the many useful recommendations which an accomplished agriculturist is enabled to offer to the farmer in re-

turn for such an indulgence would be gratefully acknowledged.*

Such appear to be the effects which promise to result from the most moderate funds requisite for a commencement of the undertaking.

(2.) *To the Agricultural advantages stated under the foregoing head, may be added the means of general education derivable from some classical seminary previously established.*

It is evident, that under confined circumstances, none of the sciences can be taught which are considered more or less subsidiary to agriculture, and hence the pupils most likely to profit by agricultural prelections would be such as had already made some little progress in the studies of chemistry, botany, geology, mechanics, or natural history in general.

If, however, it be considered expedient that any of these accessory sciences should be actually taught, more ample funds would be needed. Fixed or occasional lecturers on the required subjects would have to be secured, and the provision would require an increased outlay. Under such an establishment, younger pupils of agriculture might enter themselves; and by means of some arrangement with the proprietors of the ably-conducted Collegiate School of York, it would be possible to devise a plan by which the usual studies of a classical seminary, along with the instructions necessary for the future profession of the agricultural student, might be jointly going on, and lend their respective aid to complete the acquirements of the well-educated cultivator.

(3.) *Agricultural Education may be still more importantly promoted by the establishment of a MODEL FARM.*

France and other states add to these means of oral instruction, the paramount advantage of a MODEL FARM, cultivated by students themselves, under the direction of their teachers.

It is indeed but too evident, that no establishment for the promotion of an agricultural education can be pronounced fully complete without the advantage of a MODEL FARM, in order that practice may constantly go hand in hand with theory.

For this purpose alone, a highly cultivated farm would be absolutely indispensable and invaluable. But it is presumed that it would possess advantages beyond this point. It would afford to agricultural societies and to patriotic gentlemen, a means of testing important experiments with greater accuracy and with less expense than can be effected in any other manner—though they, of course, must be answerable for the expense, if, by such a deviation from a regular course of husbandry any expense should be incurred. Such a farm would afford an admirable dépôt for new and improved implements, and would be the best arena on which to test their respective merits. The same observation applies to new varieties of grain, of roots, or of seeds.†

Fourth:—PROSPECTUS FOR FORMING AN AGRICULTURAL SCHOOL AND MODEL FARM IN YORKSHIRE.

In judging of a prospectus best adapted to the resources and wants of our county, it will be necessary to recapitulate the different modes which have

suggested themselves in reference to a greater or less degree of pecuniary support.

1st. An agricultural school, in its most humble form, may be conducted by a single professor, with the aid of practical illustrations derived from visits to contiguous farms.—2nd. To these advantages may be added the general education derivable from some classical seminary previously established, with the proprietors of which a convenient arrangement might probably be made.—3rd. Agricultural education may be still more importantly advanced by the establishment of a Model Farm.

Now, there can be no question whatever, that the last plan, which is that of the inhabitants of Kent, is the most efficient one proposed. But whether in our own county, the public mind is so generally alive to the importance of an agricultural school, as to embark at once in the great outlay which such an institution must involve, may be strongly questioned.

It may, perhaps, be the more prudent step, as a preliminary attempt, to secure the services of an able professor of agriculture, and, for the purpose of general education, to make some convenient arrangement with the proprietors of the York Collegiate School. A remaining great object would be to raise funds sufficient to establish a MODEL FARM. When this last desideratum shall be accomplished, it is anticipated that the agricultural school proposed to be established in York will in most respects be commensurate with the wants of the community.

In correspondence with these views, the following prospectus is respectfully submitted, but with this understanding—that if the funds should, in the first instance, fall short of the means of providing a Model Farm, a less complete system, like that which has been pointed out, be attempted. A school of agriculture, although imperfect, is surely to be preferred to the absence of any seminary whatever for instruction. If the system adopted possess a capability of future extension, or be an expansible one, it will, with little effort, adjust itself in proportion to the additional means which are afforded to it for support. The urgent wants of an increasing population will achieve the rest. The demands of so many classes of society for a scientific and improved system of agricultural education cannot long be resisted.

These remarks must be considered as prefatory to the following outline:—

OUTLINE OF A SCHEME

FOR THE ESTABLISHMENT OF THE YORKSHIRE AGRICULTURAL SCHOOL AND MODEL FARM.

1. Capital from six to ten thousand pounds, to be raised by shares at 10*l.* each, with power to the committee to increase the number of shares.
2. The whole business to be conducted under the management of a committee of twenty-one proprietors, to be elected by the shareholders: seven of the committee to retire annually.
3. A professor of agriculture, and, if required, other assistant masters, to be engaged.
4. Committee to take a farm of varied soil, with suitable dwelling-house and offices, and of an extent not less than ——— acres, on a lease for fourteen or twenty-one years.
5. The farm establishment to consist of—the master, whose duties shall be to superintend the religious and moral conduct of the pupils living at the farm; to instruct them in reading, writing, arithmetic, and surveying; and to keep all the

* An idea of this kind was first thrown out by a very intelligent correspondent of the "Yorkshireman" newspaper. He considered the practical importance of such ambulatory visits to surrounding farms, as analogous to that which is derived in the course of a medical education from clinical lectures.

† These experiments might be published in the Annual Transactions of the Yorkshire Agricultural Society, and the articles themselves might be inspected by all its members.

accounts of this branch of the establishment.—A *matron*, to take the entire charge of the household and dairy department.—A *farm manager*, to superintend the farm under the direction of the committee, and instruct the pupils in all rural work.—A *dairy maid* and other servants in proportion to the number of pupils.—*Pupils* who wish to divide their time between manual farm labour and study, to have the privilege of attending the lectures on subjects more or less connected with agriculture at the Collegiate School in York; none to be received under thirteen years of age. Payment £— per annum, to be made half-yearly in advance. To wear a hat and jacket of the uniform of the College Farm.—Certificates to be given to such pupils as have made a satisfactory progress.

YORK CITY ESTABLISHMENT OF THE YORKSHIRE AGRICULTURAL SCHOOL.

This is to be a branch of the York Collegiate School. A very large school has been erected, within a few years, for the purpose of conducting a liberal, classical, and general education. It is conducted by masters of acknowledged high talents and great attainments. To the present numerous masters of this establishment, it is proposed to add lecturers on agriculture, geology, botany, chemistry, mechanics, and veterinary science. The young gentlemen attending this establishment, would be boarded with one of the masters, or otherwise in the city. They would be received on the customary terms. Three days a week they would be conducted in an omnibus, accompanied by the agricultural lecturer, to the farm, where they would be instructed in all the practical departments for six hours.

MODE OF CONDUCTING THE MODEL FARM.

The farm to be conducted upon the acknowledged best principles of husbandry, with a sole view to profit; but to accept all offers of experiment that might be tendered to them by the Royal or Yorkshire Agricultural Societies, on the express engagement, that if unsuccessful, the loss shall be defrayed by the society at whose suggestion the experiment was made. New or improved implements to be received upon loan; their merits or defects to be ascertained; and certificates to be given to the owners when the implements are returned. A general depot and museum to be held at the farm, under the direction of the Yorkshire Agricultural Society.

No gentleman enrolling his name as a shareholder to be subject to a call for money until 100 shares are subscribed for; a committee to be then formed and a banker and secretary appointed, but no shareholder to be called upon for more than one pound per share until 300 shares are taken, nor under any circumstances to be liable to a payment beyond the amount of his original shares.

It is particularly requested that persons desirous in any way of furthering the objects proposed in this prospectus, will send their names and addresses, and from such parties any suggestion on the subject will be most thankfully accepted.

CHARLES HOWARD,
Hon. Secretary,
Yorkshire Agricultural Society, York.

SWEDISH TURNIPS.—Last year a gentleman at Frensham, near Farnham, kept 100 sheep for three months on 10 acres of Swedish turnips; of course the turnips were of extraordinarily fine growth—many of them weighing upwards of 14lb., and the average of the field was 8lb., thus giving 34 tons per acre, or about

23lb. to each sheep per day. Four years previously this same gentleman kept 330 sheep on eight acres for 12 weeks in an adjoining field, and of the same quality of soil to the one described above. This was only 30 rods for 100 sheep per week; by measurement this statement would make eight bushels per rod, at 60lb. per bushel. Of the nature of the soil, and the superior methods pursued by this very capital turnip grower, it may be remarked, that the soil naturally is as poor a sand as any to be found on the Bagshot-heath district, being a ferruginous quartzon sand, the field abutting on Frensham Common, which is a waste of 10,000 acres, from which the iron clinker paving-stone is obtained for paving Farnham-street. The methods pursued by this gentleman are, deep ploughings, dunging over the whole surface, sowing early in June, single drill flat in every third furrow seam, by a single-handed drill; as soon as the plants appear, and the rows can be made out, the horse hoe is set to work; in the course of a week after, the hand-hoe cuts them to their proper distances in the row; if there is any failure of plants in the rows, they are made good by a transplanting; this is done by efficient men, when they are good-sized plants. Another hand hoeing takes place, and then the horse-hoe is run between them every two or three weeks as long as the horse and the hoe can get between the luxuriant leaves. This is done with one horse and a lad, who goes over about three acres per day. From 60 to 70 acres are thus cultivated every year by this gentleman, who has lately commenced marling his sandy grounds, from a pit he has lately discovered in a corner of his estate.

MALT.

A RETURN of the number of bushels of Malt on which the Duty has been charged in each Year, from 1810 to 1840, both years inclusive, up to the 5th day of April, in each Year, in England, Ireland and Scotland, separately and together; stated throughout in the imperial measure.

Years.	Number of Bushels of Malt charged with Duty.			
	ENGLAND.	IRELAND.	SCOTLAND.	TOTAL.

G. A. COTTELL, First General Accountant.
Excise Office, London, June 27, 1840.

SHEEP BREEDING.

"When a race of animals have possessed in a great degree, through several generations, the properties which it is our object to obtain, their progeny are said to be well bred, and their stock may be relied on; and it cannot be doubted that any breed may be improved in the same manner."—*Sir John Sinclair.*

When I consider that there are continually grazing on our fertile pastures thirty-two millions of sheep which, exclusive of the carcase, produce a yearly clip of wool of the value of seven millions of pounds sterling, employing 350,000 individuals, and ultimately yielding manufactures to the amount of, at least, twenty-one millions of sovereigns annually, my heart expands with English pride, and I am happy my lot was cast in such a country. But then comes the curdling enquiry of how is it that the good common sense of the British farmer, with appliances enjoyed by no other agriculturist in the world, still suffers his green hills to be disfigured with such an inappropriate illegitimate race of sheep? Unwilling as I am to cause pain to any one, or to assume superiority over brother husbandmen, yet imperative truth forces me to regret that even in the middle of the 19th century the following inconsiderate practice prevails:—A farmer rides a day's journey to a sheep letting, where he sees a number of animals of various pretensions, fetching, according to worth or fancy, from fifty shillings to nearly as many pounds. Now this motley batch of varying priced rams have all been bred in the same bungling way from the same flock, and by the same males. And the sheep that is now making twenty pounds is by the same sire as he that but climbs to fifty shillings; the higher priced one being but a chance hit of comeliness, without system in his production, or certainty of what will be his progeny. It could not have happened otherwise, for had those individual sheep been bred with any science or method at all there could not have been that degrading disparity in the produce of the same flock. But such a ram breeder has no help in him, for he also yearly goes as far off for his males, (there's a charm in great distances,) where he has picked out one, but also without character or pedigree, with nothing but present external appearances and smell of oilcake to recommend him; no one being able to predict whether his offspring will be ringstraked, speckled, and spotted—whether their faces will be black, grey, or white. At such a market the obtaining a showy sheep is all that can be expected or guaranteed—all the rest is clouds, darkness, or uncertainty, and probably the next crop of lambs may show patches of as many breeds, and as many contradictory defects, as there are counties in England. Therefore it cannot be too urgently pressed on the attention of sheep breeders that in hiring rams a first consideration should be to select from such top-masters only as have pedigree, uniformity, and character, super-added to a goodly appearance in their general flock.

To those farmers who are undecided from whence to have their next male sheep I respectfully submit, do not be satisfied with merely seeing a score or two of the firstlings of the flock penned up for display. Quietly go over the whole farm, and after allowance for variety of pasturage and shelter, see whether there is an uniformity in the flock; whether any promiscuous two or three score of them present such an identity as to render it difficult for individuals to be distinguished from each other. See that the males are masculine and

the females feminine, with an harmonious family likeness running through the whole. Then ask the proprietor how he procured even a flock—whether he changes it by introducing new and unknown males with every returning season? He will answer in the negative, and say he has for a quarter or half a century carefully bred only from such as he well knew, whose uninterrupted pedigree he can produce, and during that time his mutton had not deteriorated, nor his wool lost weight or quality—that he indulges in no auxiliaries, as cake, corn, or seed, for food, or sheds for shelter, but that they eat nothing but what is grown on the farm—that they are thereby fortified against debasing influences of every kind, and truly a desirable flock to breed from. My sheep being far short of perfection, though perhaps a stage or two in advance of some of my brother breeders, I beg to describe them. Abiding ever by what I have already said about the head—the head is short, round, and without angle or hollow—a tape passed from the throat round behind the ears shall about equal alike the girth from the throat over the eyes and forehead—a quiet but confident aquiline visage (no pig-faced lady for me)—ears woolly, short, well-back and down bent, not rabbit fashioned—the neck not straight lined from the rump, but set on at the shoulders at about a 45 upward angle, nor tapering over delicately towards the head, but thick, full, and fleshy along its whole length—blade-bones well spread, far back, and showing the chine above their upper working, which will produce a large open and heavy breast, not pitched downwards as in the greyhound, but rounded up to a frontage like the forekeel of a ship. This enables the sheep to look well in the face, and gives it a presence as if standing up hill from whatever aspect it may be viewed, that is, gradually rising from the loin to the setting of the neck, which again springs upwards, thick, full, and muscular—nor do I object to a slight hollow about the middle of the back, capacious loin, spread out hips, and well connected rumps—wide and fleshy in the twist, legs short light boned, and under the sheep, not stuck out like four props to a hay stack. I covet not a thick tallow tail, but must have a well woolled belly. Other breeders possibly have better sheep; I know what mine cost, and what they pay, and in this respect am a contented man. I had more to say, but fear I am trespassing.

PRACTICAL.

P.S.—Of course, I have been speaking of the muscular frame, not of the fatty obliteration of all form, in my flock of sheep.

THE GROWTH OF PLANTS.—A profitable application of electricity, Dr. Darwin observes, to promote the growth of plants, is not yet discovered; it is nevertheless probable that, in dry seasons, the erection of numerous metallic points on the surface of the ground, but a few feet high, might, in the night time contribute to precipitate the dew, by facilitating the passage of electricity from the air into the earth; and that an erection of such points higher in the air, by means of wires wrapped round tall reeds, or elevated on buildings, might precipitate showers from the higher parts of the atmosphere. Such points erected in gardens might promote a quicker vegetation of the plants in their vicinity, by supplying them more abundantly with the electric ether.

ON FERN.

Fern (A. S. faran, vaeren, Dut.; fearn, Sax.; fahen, Ger., to go, as the plant is very abundant, and everywhere meets the traveller; filum, Lat., quasi filatim incisae) forms the order of "Filices," in the cryptogamous class of plants, in the artificial system of arrangement. The genera of ferns are numerous; but one plant only comes under the notice of agriculture, the common brake or the "Pteris aquilina," from πτερον, Gr., a wing, is very generally diffused over uncultivated grounds and heaths, and very often found on soils of good quality. It abounds in marshy loams, in dells and ravines, and on the sides of banks and mountains, where it grows luxuriantly on sands and gravels, on clayey and mixed substrata, and very generally on white sands mixed with gravel, with a thin vegetable layer, constituting soils of the poorest quality. The roots spread horizontally and often deeply into the ground, and are difficult of extirpation—frequent mowing, ploughing, and dunging, have been recommended, and above all, the pouring urine upon them. Sheep folded closely on fern ground will banish the plants by means of the dung and urine.

Fern has a salt mucilaginous taste, and was formerly much used in medicine, and the country people yet retain it in powder to destroy worms, and reckon a bed of the green plants of it a sovereign cure for the rickets in children. The stems tied together make a very durable thatch, afford a violent heat when burned, and are used where coals or fuel is scarce, to heat ovens, and to burn limestone. The roots boiled in wash are much relished by swine, and in Normandy they are mixed in bread, and in Siberia they are brewed in ale, with one-third part of the roots to two-thirds of malt. It is very satiating, and is used in preparing kid and chamois leather.

When this plant is cut in a green state, and left to rot on the ground, it very much improves the land, and the ashes afford double the quantity of salt of any other vegetable. The ashes are often mixed with water and formed into balls, heated in the fire, and then used as an alkaline ley for scouring linen. Fern ashes yield about one-ninth of their weight in salt, principally the sulphate and sub-carbonate of potash. 1000 parts of the plant, cut in August, and thoroughly dried, afforded 36.46 of ashes, which yielded by lixiviation 4.5 of salt. One hundred parts of each vegetable being thoroughly dried, were burned by an open fire, and the ashes weighed, and then lixiviated till all their saline contents were extracted, gave as under:—

100 parts.	Ashes.	Salt.	Salt from 100 parts of ashes.
Nettle	10.67	2.5	23.4
Fern	5.	0.62	12.5
Ditto	3.64	0.42	11.6
Barley	33.3
Sonchus arvensis	10.5	1.96	18.6
Heath	11.5
Fumitory	21.9	7.9	36.
Wormwood	9.74	7.3	74.8
Sallow	2.8	0.28	10.2
Elm	2.3	0.39	16.6
Oak	1.3	0.15	11.1
Beech	0.58	0.12	21.9
Aspen	1.32	0.07	6.1
Fir	0.34	0.04	13.2

The proportions of the saline substances to the earthy in plants is smallest in woods. Fern, 4.25; red clover, 0.78; vetches, 27.5; beans and stalks, 20.; and varies in other plants from 1 to 5; in oats 1 to 8, in rye 1 to 8, in wheat 1 to 3, in turnips 1 to 3.33, in potatoes 1 to 1.3, and in parsnips 1 to 1; in flax 1 to 1.7, in hemp 1 to 8. 100 parts of fern gave 3.221 of earths.

Hence we see that succulent herbaceous plants yield a much greater proportion both of ashes and salt, than the shrubby and ligneous structures, but they were all well dried; and wood will lose only one-third or one-fifth in drying, whereas many succulent plants will lose as much as nine-tenths, which may account for the difference.

Ferns make a good litter for cattle, and are usually dried and stacked for that purpose. They remain long unchanged, and should be laid in the bottom of the yards, or in similar moist places, where they may be completely saturated. The ashes are used as a top-dressing, mixed or unmixed, with good effect. The plant should be cut before it decays, and when green, either for litter or for ashes, for plants that contain much fixed alkali are liable, when withered, to lose it by every shower that falls. Fern is best adapted for summer litter for cattle and horses in the yards; when dried, like all vegetable fibre, it is very insoluble and indestructible by spontaneous change, and has in excess the general toughness and elasticity produced by the stringy intermixture of the minute threads. These fibres differ much in plants, being very flexible or firm, hard and brittle, and diminish in wood and herbaceous plants. It consists of carbon, oxygen, hydrogen, and a little azote. The cutting of dried fern into short lengths for litter, as recommended in the case of rank straws, by a change in the common cutters, might facilitate the decomposition and future management as a manure.

J. D.

ON STALL AND HOUSE-FEEDING OF RAMS.

SIR,—Seeing the system of house and stall-feeding of rams fast creeping into practice amongst some of the first breeders in the kingdom, I would wish, and feel obliged to, some of your numerous and enlightened readers, to inform me what are the more especial and particular advantages to be obtained from such a custom.

Is the health of the animal improved by it?

Is the animal more capable of performing the duties required of him in the tupping season?

Or, is that immense load of flesh (being five stone heavier than if he were in the field in the usual way,) put on the animal to make his appearance fine to the eye and hand of the purchaser only?

Does not the system of keeping him shut up in a house or stall six months or more in the year, make him naturally indolent, less active, and more incapacitated to the duties he has to perform?

And, as he has been reared as a hot-house plant, will not his health be greatly impaired when exposed on Cotswold Hills or the wolds of Yorkshire, and the most bleak situations?

A reply to these important questions will very greatly oblige,

Sir, your obedient servant,

A CONSTANT READER.

MANURING THE SOIL AND MAKING HOTBEDS.

"Most persons imagine that manure is all that is wanted to make a garden fruitful; and thus, if the fruit-trees do not bear, and the flowers and vegetables do not thrive, manure is considered the universal panacea. Now, the fact is, that so far from this being the case, most small gardens have been manured a great deal too much; and in many, the surface soil, instead of consisting of rich friable mould, only presents a soft, black, shining substance, which is the humic acid from the manure saturated with stagnant water. No appearance is more common in the gardens of street-houses than this, from these gardens being originally ill-drained, and yet continually watered; and from their possessors loading them with manure, in the hope of rendering them fertile.

"As it is known to chemists, that it is only the humic acid, and carbonic acid gas, contained in manure, which make that substance nourishing to plants; and as these acids must be dissolved in water before the roots can take them up, it may seem strange that any solution of them in water, however strong it may be, should be injurious to vegetation. The fact is, however, that it is the great quantity of food contained in the water that renders it unwholesome. When the roots of a plant, and their little sponge-like terminations, are examined in a powerful microscope, it will be clearly seen that no thick substance can pass through them. Thus water loaded with gross coarse matter, as it is when saturated with humic acid, must be more than the poor spongioses can swallow; and yet, as they are truly sponge-like, their nature prompts them, whenever they find moisture, to attempt to take it up, without having the power of discriminating between what is good for them and what will be injurious. The spongioses thus imbibe the saturated liquid; and loaded with this improper food, the fibrous roots, like an over-gorged snake, become distended, the fine epidermis that covers them is torn asunder, their power of capillary attraction is gone, and they can neither force the food they have taken up into the main roots, nor reject the excrementitious matter sent down to them from the leaves, after the elaboration of the sap. In this state of things, from the usual circulation of the fluids being impeded, it is not surprising that the plant should turn yellow, that its flowers should not expand, that its fruit should shrivel and drop off prematurely, and that in the end it should die; as, in fact, it may be said to expire of apoplexy, brought on by indigestion.

"All soil, to be in a fit state for growing plants, should be sufficiently loose and dry to allow of water passing through it intermixed with air; as water, when in this state, is never more than slightly impregnated with the nutritious juices of the manure through which it has passed. The spongioses are thus not supplied with more food at a time than they can properly take up and digest, and a healthy circulation of the fluids is kept up through the whole plant. But what, it may be asked, is to be done with a garden, the soil of which has become black and slimy like half-rotten peat? The quickest remedy is covering it with lime, as that combines readily with the humic acid, and reduces it to a state of comparative dryness; or, if the subsoil be good, the ground may be trenched, and the surface-soil buried two spits deep; in either case, it will be necessary thoroughly to drain the garden to prevent a recurrence of the evil.

"All the different kinds of soil found on level ground, consist of two parts, which are called the surface soil and the subsoil; and as the subsoil always consists of one of the three primitive earths, so do these earths always enter, more or less, in the composition of every kind of surface-soil. The primitive earths are—silice, (which includes sand and gravel,) clay, and lime, which includes also chalk; and most subsoils consist of a solid bed or rock of one or other of these materials, probably in nearly the same state as it was left by the Deluge. The surface-soils on the contrary, are of comparatively recent date; and they have been slowly formed by the gradual crumbling of the subsoil, and its intermixture with decayed animal and vegetable matter, and with other soils which may have been accidentally washed down upon, or purposely brought to it. In fields and uncultivated places, the surface-soil is almost as hard, and as coarse in its texture, as the subsoil on which it rests; but in gardens which have been long in cultivation, the surface-soil becomes so thoroughly pulverized by frequent diggings, and so mixed with the manure and decayed vegetables which have been added to it from time to time, that it is changed into the soft, light, fine, powdery substance called garden-mould. If the subsoil be naturally porous or well drained, this mould, however rich it may be made by the addition of decayed vegetable matter or animal manure, will always continue friable; and as long as it does so, it will be fit for the growth of plants: but if no vent be allowed for the escape of the water, and it be continually enriched with manure, it will be changed in time into the black slimy substance that has been already described.

"Surface-soil is called peat-earth when it is composed of decayed vegetable matter, without any mixture of animal manure; and, as this excess of vegetable matter could neither be produced nor decayed, without abundance of stagnant moisture, this kind of earth is almost always found on a clayey subsoil, which prevents the water which falls upon it from escaping. Peat-earth has a spongy, elastic feeling when trodden upon, arising from the quantity of water that it holds, and it can only be rendered fit for cultivation by draining. In its elastic state it is what is called in Scotland a moss, and in England a peat-bog. Should the water, instead of being afforded a vent by drainage, be suffered to accumulate for many years, till it completely saturates the peat, the soil becomes what is called a morass or quagmire; and it can no longer be trodden on, as it will engulph any substance resting upon it. A still further accumulation of water will, in the course of years, cause the bog to burst its bounds, and overflow the surrounding country; as the Solway-moss did many years ago, and as bogs in Ireland have done frequently. An excess of vegetable matter on a silicious subsoil, differs from the common black-peat in retaining less water; and in being mixed with a portion of the primitive earth, which, from its loose texture, becomes easily detached from the subsoil. Peat in this state is called beath mould.

"The most productive soils are those in which several ingredients are combined in proper proportions; and if any one of the primitive earths preponderates, the soil becomes comparatively unfertile. Thus the best soil for gardening purposes is generally allowed to be a calcareous loam on a chalky subsoil; and this sort of soil is composed of nearly equal parts of lime, sand, and clay, enriched by depositions of decayed animal and vegetable matter. The next best soil is a sandy loam, composed of

clay and sand, enriched by decayed animal and vegetable substances, and resting on a gravelly or sandy subsoil. The worst soils are peat and sand. A poor sandy soil is necessarily a nearly barren one; because it will not retain either water, or the nutritious juices from manure, long enough to afford nourishment to the plants grown upon it; and it is obvious that a soil of this kind can only be rendered fertile by mixing it with clay; which would change it into a sandy loam.

"A stiff clay is unfertile from its attracting moisture, and retaining it round the roots of the plants till they become swollen and unhealthy. It also retards the decomposition of manure, and obstructs the progress of the roots, which waste their strength in the efforts they make to penetrate, or twine round its adhesive clods. Soils of this description are improved by a mixture of sand, gravel, road-grit, or any substance which tends to separate the particles of the clay, and to render it light and friable.

"Chalky soils succeed better unmixed, than any of the other kinds; but chalk being a carbonate of lime, can hardly be called a primitive soil. The chalk, however, from its whiteness, is colder than any other soil; as it does not absorb, but reflects back the rays of the sun. Rain also penetrates into it very slowly, and not to any great depth. Chalk mixed with sand forms a kind of calcareous loam admirably adapted for growing vegetables; and chalky soils are peculiarly susceptible of improvement from manure.

"*Manures.*—The kind of manure generally used in gardens are horse or cow dung, and decayed vegetable matters; the manure in both cases being suffered to lie in a heap to rot before it is spread on the ground, in order that its component parts may be decomposed by fermentation, and thus brought into a fit state to afford food to the plants. Old hot-beds or mushroom beds are thus well adapted for manuring a garden; and when fresh stable dung is employed for that purpose, it is generally thrown into a heap, and turned over several times till the fermentation has abated, before it is dug into the ground. As, however, a great quantity of carbonic acid gas is evolved, and escapes during the process of fermentation, and as it seems a great pity that so much of the nutritious properties of the manure should be lost, it is now customary to cover the dunghill with earth, into which the gases will rise during the process of fermentation, and in which they will deposit the greater part of their nutritious properties. A quantity of earth should also be laid round the dunghill, to imbibe the liquid that runs from it; and this earth, part of which must be removed and fresh added every time the dunghill is turned over, will be found very nearly as valuable for manuring the beds of a garden, as the manure itself.

"The modes of applying manure differ according to the difference of the soils. For sandy loams, thoroughly rotten dung, either from an old hot-bed, or from a dung-hill sufficiently decayed to be cut easily with the spade, or the earth that has covered a dunghill, during the process of fermentation, should be laid on the surface of the soil, and dug in. In very poor sandy soils, rotten manure, or earth from a dunghill, should be laid on the surface of the soil, and not dug in: being covered, if hot dry weather be expected, with leaves, straw, or the branches of trees cut off in pruning; or occasionally sprinkled with water. Soils of this description, and loose sands, are frequently improved in the south of France and Italy, by sowing them with seeds of the common white lupine, and then, when the plants

have come up and grown about a foot high, ploughing or digging them into the soil. The green succulent stems of the lupines, when thus buried in the soil, supply it with moisture during the process of their decay; and thus nourishment is afforded to the corn, which is immediately afterwards sown upon the soil for a crop. Clayey soils should have unfertilized manure, mixed with undecayed straw laid in the bottom of the furrows made in digging: that the process of fermentation, and the remains of the straw may operate in keeping the particles of the soil open, or, in other words, in preventing their too close adhesion. Lime (though when burnt it becomes violently caustic, and will destroy and waste all the manure applied with it), as carbonate of lime, or chalk (in which state only it can properly be called a soil), retains the manure applied to it longer than any other soil. Rotten manure may thus be dug into chalk, with the certainty that it will be preserved from further decay for a very long time, and that every shower will work a small portion of its fertilizing juices out of it, and carry them into the soil, where they will be thus presented to the plants in the best possible state for affording wholesome food.

"Peat soils may be improved by the addition of quicklime as a manure, which will absorb the superabundant moisture which they contain; or they may be mixed with sand, gravel, or clay, to give them firmness and tenacity, and then with a small quantity of animal manure. Sandy peat or heath-mould is very useful in gardens for growing heaths, rhododendrons, kalmias, or any plants with fine hair-like roots; and from the quantity of vegetable matter that it contains naturally, it does not require any manure, more than what is furnished by the decaying leaves of the plants grown in it.

"Nearly the same rules apply to decaying leaves and other substances used as manure, as to stable-dung. They may be buried in an undecayed state in clayey soil, when it is the object to separate the adhesive particles of the clay by the process of fermentation; but their component parts should be separated by fermentation before they are applied as a manure to growing plants. Vegetable mould (that is, leaves thoroughly decayed and mixed with a little rich loam) is admirably adapted for manuring the finer kinds of flowers, and plants in pots. There are many other kinds of manure used in gardens occasionally, such as the dung of pigs, rabbits, and poultry, grass mown from lawns, parings of leather, horn-shavings, bones, the sweepings of streets, the emptying of privies, cess-pools, and sewers, the clipping of hedges and pruning of trees, weeds, the refuse of vegetables, pea haulm, &c. All these should be fermented, and applied in the same manner as the common kinds of manure.

"The following is a summary of the general rules to be observed in manuring and improving soils:—Never to use animal manure and quick-lime together, as the one will destroy the other. To use lime as a manure only in very sandy or peaty soils, or in soils abounding with sulphate of iron. To remember that rotten manure is considered to give solidity; and that unfertilized manure, buried in trenching, has a tendency to lighten the soil. To dilute liquid manure from a dunghill with water, before applying it to growing plants; as otherwise, from the quantity of ammonia that it contains it will be apt to burn them. To cover and surround dunghills with earth during the process of fermentation, to absorb the nutritious gases that would otherwise escape. To remember that the manure of cows and all animals that chew the cud, is cold and suited to a

light soil; and that the manure of horses, pigs, and poultry is hot and suited to a firm soil; also that all manure, when well rotted, becomes cold in its nature, and should be treated accordingly. To remember that all mixed soils are more fertile than soils consisting only of one of the three primitive earths, viz., lime, sand, or clay; and never to forget that too much manure is quite as injurious to plants as too little.

Formation of hot-beds.—Though nearly all the kinds of manure which have been enumerated may be used occasionally for hot-beds, the only materials in common use in gardens, are stable manure, dead leaves, and tan. The first of these, which is by far the most general, consists partly of horse-dung, and partly of what gardeners call long litter, that is, straw moistened and discoloured, but not decayed.

The manure is generally in this state when it is purchased, or taken from the stable, for the purpose of making a hot-bed.

"The necessary quantity of manure is procured at the rate of one cart load, or from twelve to fifteen large wheelbarrowfuls to every light, as the gardeners call the sashes of the frames, each light being about three feet wide; and this manure is laid in a heap to ferment. The heap should then be covered with earth to receive the gases evolved during fermentation, and earth laid round it to absorb the liquid manure that may drain from it. In about a week the earth may be removed, and the manure turned over with a dung-fork, and well shaken together; this operation being repeated two or three or more times, at intervals of two or three days, till the whole mass is become of one colour, and the straws are sufficiently decomposed to be torn to pieces with the fork.

"The size of the hot-bed must depend principally on the size of the frame which is to cover it; observing that the bed must be from six inches to a foot wider than the frame every way. The manure must then be spread in layers, each layer being beaten down with the back of the fork, till the bed is about three feet and a half high. The surface of the ground on which the hot-bed is built, is generally raised about six inches above the general surface of the garden; and it is advisable to lay some earth round the bottom of the bed, nearly a foot wide, that it may receive the juices of the manure that will drain from the bed. As soon as the bed is made, the frame is put on and the sashes kept quite close, till a steam appears upon the glass, when the bed is considered in a fit state to be covered three or four inches deep with mould; observing, if the bed has settled unequally, to level the surface of the manure before covering it with earth. The seeds to be raised may either be sown in this earth or in pots to be plunged in it.

"The proper average heat for a hotbed intended to raise flower seeds, or to grow cucumbers, is 60 deg.; but melons require a heat of 65 deg. to grow in, and 75 deg. to ripen their fruit. This heat should be taken in a morning, and does not include that of the sun in the middle of the day. When the heat of the bed becomes so great as to be in danger of injuring the plants, the obvious remedy is to give air by raising the glasses; and if this be not sufficient, the general heat of the bed must be lowered by making excavations in the dung from the sides, so as to reach nearly to the middle of the bed, and filling up these excavations with cold dung which has already undergone fermentation, or with leaves, turf, or any other similar material which will receive heat but not increase it. When the heat of the bed falls down to 48 deg. or lower, it should be raised, by

applying on the outside fresh coatings of dung, grass, or leaves, which are called linings.

"When hot-beds are made of spent tanner's bark or decayed leaves, a kind of box or pit must be formed of bricks or boards, or even of layers of turf or clay, and the tan or leaves filled in so as to make a bed. Where neatness is an object, this kind of bed is preferable to any other; but a common hot-bed of stable manure may be made to look neat by thatching the outside with straw, or covering it with bast mats, pegged down to keep them close to the bed."—*Mrs. Loudon's Gardening for Ladies.*

PERSICARIA (FOR FLIES IN HORSES).—The herb or juice of the Cold Arsmart (Arsmart Persicaria or Peachwort), also called Mild or Dead Arsmart, with a leaden-coloured spot on the leaf, and not hot and biting, but rather sourish to the taste, put to a horse or other cattle's sere, "will drive away the fly in the hottest time of summer." Dr. Short, who confirms this statement of Culpeper and Salmon, says it will "drive away flies and all vermin, being strewed in the place where they are." It is called the Mild, or Cold, or Spotted Arsmart, or Persicaria, or Peachwort, because the leaves are so like the leaves of a peach tree. It was also called Plumbago, because of the "leaden coloured spot placed on the leaf," which distinguishes this the Mild or Cold from the Hot and Biting Pepperwort. It has far broader leaves than the spot. The Mild of the old Herbalists is the species called the Polygonum Persicaria by modern Botanists, who describe it as having a round reddish branching stem; leaves one after another, lance-shaped, set at the great red joints of the stalk; they have semicircular blackish marks, or as Sir James Smith calls them, "black lunato spots" on them, usually either bluish or whitish, with such like seed following. The root is long, stringy, and perishes yearly. The taste of this herb is rather sour, like sorrel, or else a little drying, or without taste. The Hot Arsmart, called also Water Pepper, and Biting Persicaria, has no spot on the middle of the leaf; it grows not so tall or high as the mild; it has many lax, interrupted drooping leaves, of the colour of peach leaves; it is very seldom or never spotted; in other particulars, it is very like the Mild, but may easily be known from it by taste, for the Hot makes the tongue smart, the other does not. Besides it has no spot on the middle of the leaf, like the other. The stem is about one foot and a half high, but this is the shorter. Both flower in June, and seed in August. The Hot Arsmart, strewed in a chamber, will soon kill or expel all the fleas in it. The old Herbalists say, "a good handful of the Hot-Biting Persicaria, put under a horse's saddle, will make him go vigorous and travel fresh and lustily again, although he were half-tired before." No doubt, for it acts like a red poker. They are found in dry ditches and watery places. The Mild chiefly about ponds and marshes. The flowers of both the Hot and Cold Arsmart are, I believe, crimson, but those of the Hot are dotted.

FRENCH SHEPHERDS.—The French shepherds induce their flocks to follow them to and from pasture, instead of driving and alarming them by dogs as we do in England. The shepherd effects this by bringing up two or three lambs by hand, which, by following him ever afterwards when called, cause the whole flock to do the same. But the shepherd's perpetual call upon these proteges of his, naturally induces the flock to move when they hear his voice; and to persons to whom such scenes of rural imagery are not devoid of interest, it is a very gratifying sight. This, too, is classical: Statius, in his "Thebaid," compares the parental care of the Grecian General, Etæocles, to a shepherd leading out his sheep from their fold; and Homer illustrates the joy which Æneas displays on viewing the discipline of his troops, by that of a shepherd, on seeing his flock in good plight as he leads them to water.

ON THE OPERATION OF BUDDING.

Budding is one of the most refined and delicate operations of the gardener; and the month of August (the early weeks of it particularly) is the season in which it is usually performed with the greatest promise of success. It is the object of this article not only to render the process intelligible in all its parts, but to elucidate the causes of the union which takes place between the stock and bud. In order to this, the organization of the latter must be considered; and we therefore refer the reader to the following brief compendium of what appears to be the received opinion of the best physiological Botanists of the present day.

A *bud* is the rudiment of a branch, no branch can be formed unless a bud, in one condition or other has existed, though from some cause it be not revealed to the eye, and frequently is never excited into growth. "A leaf bud consists of a minute conical portion of soft succulent cellular tissue, enveloped in scaly, rudimentary leaves, closely applied to each other. The centre of the bud is the seat of its vitality: the scales that cover it are the parts toward the development of which its energies are first directed."

In this opinion any one must coincide who dissects a bud while in the early progress of its swelling, and then consider that, "a leaf-bud usually originates at the axil, or angular base of a leaf, and that its cellular centre communicates with that of the woody centre of the stem. In fact, if a juicy stem be cut across below, and in the direction of a swelling bud, a trace of whitish pithy matter may be discerned, from the bud to the central pith. In making this assertion from observation, as well as from one of the authorities alluded to, I refer at present exclusively to trees or shrubs with perfect stems, wherein a layer of bark and wood, crossed by medullary rays, are annually produced; and the fact tends not only to determine one of the functions of the rays, but to show that the central pith is the fountain of nutriment to, if not the *origin* of, all buds; and that therefore, when even the pith becomes absorbed, and extinct, it may reasonably be conjectured that the development of the branches and head are nearly at an end.

A *leaf-bud*, it is further stated, has three special properties, those of growth, attraction, and propagation. In warm, damp weather under the influence of light, it has the power of increasing in size, of developing new parts, and so, of growing into a plant. It is in itself a complete body, consisting of a vital centre covered by nutritive organs or hairs. "Although it is usually called into life while attached to its parent plant, yet it is capable of growing as a separate portion, and of producing a new individual in all respects the same as that from which it was divided; hence, it is a *propagatory organ* as much as a seed."

This fact admitted, we possess a key to the operation of budding; a process which can be performed whenever the bark of the *stock* will rise freely, without tearing into fibrous threads, (through a rigid adherence to the wood beneath it), and that of the amputated bud separate with equal clearness and facility. Common roses (not the Chinese), and fruit trees, are generally budded in August, because at that period sufficient vital activity remains to effect the union of parts, yet not enough of it, owing to the declining influence of solar power, to stimulate the buds to growth.

I shall now copy nearly verbatim, the *directions* for the performance of budding given in the *Penny Cyclopædia* under that head, in vol. v. p. 532; interspersing remarks on several of the paragraphs which may render them more familiar to the young practitioner, first observing that the best stock for the reception of a bud is a clear firm shoot of the wood produced in the present spring, and which is strong and elastic, but not hard and woody. The bark should be clear, and smooth, and as was before said, ought to rise freely from the wood. Again, that as *standard roses* are greatly admired for their beauty, and apples and pears are found to succeed admirably, producing handsome trees in a very few years, when young seedling stocks with one shoot only of the spring growth, are budded, the directions will be restricted to those, though they will be suitable to every species of tree or shrub.

Suppose then a straight, dog-wood stock taken from the wood, three to five feet high, to have made three stout shoots during the summer at its summit. Let these be cut off to the length of six inches, as early as possible, and then having selected a shoot of any favourite rose whereon the buds appear fully formed and somewhat projecting, "with a very sharp knife one of such buds, and the leaf to which it is auxiliary are pared off with about half an inch of bark adhering at the upper end, and an inch and a half at the lower end. By holding the leaf firmly between the finger and thumb of the left hand, with the wounded side of of the paring uppermost, the small slip of wood which adheres to the bark may be made by a jerk to come away from the paring, leaving nothing but the cellular centre of the bud fixed to the bark."

This centre is called by gardeners, the root of the bud, and it is extremely liable to be torn away, as it adheres firmly to the medullary process which passes through the sap-wood, and joins the internal pith below it. If this occur, a hole or depression will be observed just in the centre of the bud, below the inner surface of the bark, which it will be manifest must entirely prevent the base of the bud from coming into contact with the wood of the stock. On the contrary if the bud *retain* its roots, a few lacerated fibrous processes will be seen to repose on the denuded bark, and these will produce a slight elevation rather than depression, which cannot fail to make the bud press upon the wood of the stock. Nine buds of ten will be deprived of this vital centre, if the end of the strip *below* the bud be first raised, but by raising the strip at the upper end, and, as it were coaxing it away, many perfect buds can be secured. The wood may also be carefully pared down by the knife, so as to leave only the bud and its centre.

"This done an incision is to be made transversely through the bark of the stock, and a second longitudinally, at right angles to the first, and in a direction downwards, so that the two together resemble a sort of T. The operator then with a flat ivory blade, lifts up the bark on each side of the long incision, so as to separate it from the wood, and inserts beneath it the prepared bud, which is gently pushed downwards till the bud itself is a little below the transverse line."

These directions are very correct, but to obey them conveniently the budder ought to stand over his work, and to bend down the stock till it be below his eye and hand; he should hold the prepared bud between his lips, and make the incisions one after the other in each shoot (if there be two or

three on a stock) in a clean part, not two inches above its junction with the main stem.

The *long cut* must be fully opened, and its lips kept apart by the haft, so that the tender bark of the bud may slip in without interruption or folding up, and when inserted to its proper depth, which is about one fifth of an inch above the bud, the upper part of the bark must be cut off, laying the knife along the transverse cut, which thus becomes a channel to its edge; and finally drawing up the bud till the newly cut upper edge repose securely against that of the cross cut of the T. This position and junction are important, as they expose the two barks to the intercommunication of the true sap of each.

In budding roses, the *leaf must be entirely cut away*, leaving only about half an inch of its foot-stalk by which the bud with its bark can be conveniently handled, but if the leaf remains, it is found to dry the bud by transpiration, and thus to render the operation abortive.

The bud being securely encased, "a ligature of soft wetted bass is carried round the stem so as to bind the bud firmly to the new wood on which it is placed. If the operation is well performed, the bud will thus be fixed on a new plant, in the same position as it occupied on the branch from which it was taken; the mouths of the medullary rays of its bark will unite with those of the wood of the stranger plant; it will be kept in contact with a continual supply of food oozing out of the albumen," (sapwood) on which it is placed, it will absorb that food, and soon accustom itself to its new position.

Then, when the growing season arrives, it will be stimulated by light and warmth to attract sap from the wood to which it has adhered, it will push forth new wood of its own, over that which it touches, and thus will form as intimate a union with its stock as it would have formed with its parent plant. In order to enable it to do this, it is customary to head down budded branches to within a few inches of the buds, so as to compel the sap which oozes from the stock to expend itself on the former; a few natural buds, near the inserted bud are allowed to push sufficiently to attract the sap to their neighbourhood, and are then destroyed. When the bud has pushed to the length of a few inches, it is tied to the stem so as to be secured from being broken off by accident; and finally, when it is quite secure, that small portion of the stem of the stock which had been left above the bud in the first instance, is cut away, and the branches produced by the bud become the head of the tree.

This is capital and philosophical authority, which cannot mislead, therefore I have only taken the liberty to modify a word or two occasionally in order to remove the slightest ambiguity. To corroborate the views of the writer, I will add that the theory of the function ascribed to the *medullary processes* (known by the name of silver grain) corresponds with that of the late Mr. Knight, who considered them as the channels of intercourse between the newly formed bark and wood, and the central organs of the stem. In fact, we always find wood, however old it may be, even the most consolidated heart-wood, to retain much moisture, it therefore is natural to conclude, that specific fluids are conveyed by channels, laterally, across the several layers which constitute the wood of a tree.

The first process of budding, to insure success, is that which causes compression, so as to fix the

shield of bark by means of its own moist surface, to that of the wood of the stock. The ligature of bass, which ought therefore to be tough, flat, and moist, is to be passed so firmly over the incisions below and above the bud, as to drive off the air from between the surfaces, that the bark may adhere to the albumen, as a boy's leather-sucker adheres to a wetted stone. This pressure being made by the ligature, the interflow of prepared sap and the ultimate inoculation of vessels will be duly effected.

It may be inquired why,—if the bud form new layers of wood of its own, and never borrow any of the qualities of the stock, but remain true to itself—why every future shoot from the stock should still also retain the quality of that stock, and not be influenced by the head of the tree? The reply to such an inquiry will be this—The *stock* at the time when it is budded retains a great number of latent buds, fed by the pith, some of which pass through the layers of the tree from time to time, and develop themselves externally. These being pre-organized are not changed, and therefore retain their original character, since whatever processes the bud may send down the stock it *transmits no buds*. All such developments are made upwards, for all were included in the first inserted germ, and however minute at the time they are only developments, not creations. This is very wonderful, it involves infinite minuteness, but, nevertheless, it is not in any degree less true; and to evince the correctness of the hypothesis, a person has nothing more to do than to bud a young seedling apple or pear stock, according to the tenor of the foregoing rules, and to watch the event. The bud will form the head, developing bud after bud, till at length it attains the dimensions of a full grown tree. The stock also will protrude a few shoots from its latent buds, which, if neglected at first, might contend with and subdue the shoot of the inserted bud. But if obliterated as they appear, will either vanish, as in an old rose stock, or become mere dwindling sprigs. In the mean time the stock thickens, acquires new layers, and remains the vehicle of nutriment to the head, and nothing more.

Nothing more need be added at present in the form of theory or practical direction; yet one further extract may be given from our authority which deserves much attention. A bud to be successful can only be inserted into a stock nearly related *botanically*—"Thus, roses will bud upon roses, but not upon currants, as is vulgarly supposed. Apples will bud upon pears or thorns; pears upon medleys and quinces; and apricots upon plums—because all these species are closely related; but an apple will not bud upon a plum or peach, because, although they are allied to a certain degree, yet their consanguinity is not sufficiently strong."

CHICORY.

SIR,—I shall feel obliged if any of your readers will inform me of the nature of the grass chicory: whether it is useful for soiling cattle, the method of cultivation required, and where seed may be procured?

I remain, Sir, your obedient servant,

A GLOUCESTERSHIRE FARMER.

May 18th.

ON A SIMPLE LIQUID MANURE CART.

By H. WOOD, Esq., of BRAMDEAN HOUSE, HAMPSHIRE.

(From the Journal of the Royal Agricultural Society.)

The agriculturist on the Continent contrives that the drainings of his kitchen and out-offices should empty themselves into the dung-heap, from which the surplus should be discharged and removed by a simple water-cart to his meadow or garden. The stables and cow-houses or sheds have small wells to receive the urine drained from the cattle, and the grass in summer being cut for them, the ground after each cutting is watered with the collected urine, diluted with a proper quantity of water, according to the dryness of the season. I have adopted this system in my own farm, and the stalls of my stable are sloped to iron gratings in their centres, which cover a well of a foot square, communicating with a drain constructed with the common circular pot used for draining land, and running the whole length of the stable, with a fall of about half an inch to a foot. At the end of this drain, outside the stable, I have constructed a masonry-vat to receive the urine drained from the stable, and my servant, after cleaning his horses, throws down two or three pails of water over that grating which is furthest removed from the vat,

the drain being thus washed down throughout its length, and the whole kept quite clean and free from smell. The drains of my house and scullery are above ground, and run into the dung-heap, which is thus always kept moist; and the salt and grease contained in the washings of the house are absorbed by the dung, which, without this aid in dry weather, would not be converted into manure. The advantage of this arrangement is, that nothing is wasted, and there is no necessity for the various contrivances in use to destroy the smell of sinks, which are such nuisances to most houses; for the pump being at the head of the house-drain, my servants are enabled to wash down the latter daily without any trouble, and in dry weather to keep the dung-heap moist. When the vat attached to the stable is filled, I have the contents removed to the cart, which is removed with the aid of a horse or two men, to the meadow. I have adopted a similar plan in my farm-yard for securing the most valuable part of the manure in winter, when the dung is unable to absorb the rain, by the construction of a vat to receive the surplus drainings.

My water-cart consists of a wine-pipe, mounted on a pair of Indian wheels without an axle, and consequently placed so low that a person is enabled to fill it with ease while standing on the ground. The following sectional elevation and plan are drawn to a scale of a quarter of an inch to the foot.

The greatest advantage of this plan is, that little iron is required in its construction, the weight of the axle-tree being also saved. In point of strength it has all the advantages of the common pulley, for the iron which supports the wheel is only one inch thick, and would support any weight which two or three horses could draw.

Bramdean House, near Alresford, June 1840.

SHEEP.—The Sydney Herald of January 13, publishes in a supplement the subjoined notice of the arrival at that place of the Kentish sheep, presented by Mr. John Palmer, of Herne Common, to the Messrs. Denne, on their departure from this country to Australia:—“A few days since, observing some sheep which displayed a very beautiful symmetry, on board the steamer Tamar, we made some inquiry, and found that they be-

longed to two gentlemen named Denne, who arrived in the colony by the ship Mellish, a few months since. These sheep are of an improved Kentish breed, and are from the celebrated flocks of Mr. John Palmer, of Herne, near Canterbury. Great trouble has been expended upon this breed, which has been brought to such perfection that the fleeces weigh upwards of six pounds, and a six months' fleece weighed four pounds and a half. Notwithstanding the great weight of the fleece, the staple is uncommonly fine and strong, so much so that for some years past the whole of the wool has been purchased for the French manufacturers, at prices varying from 2s. to 2s. 3d. per lb. The wool was used by the French for their merino and cashmere fabrics, and it is only a few months since that the Norwich manufacturers were enabled to discover where the French obtained the material for these articles, and it is expected that now that they have discovered it, there will be competition between the Norwich and French ma-

nufacturers, and that the price of wool will increase. Messrs. Denne, who were farmers and graziers to a very considerable extent in Kent, have imported these sheep with a view of crossing them with the Merino and Saxon breeds in this colony, and so highly are they esteemed by competent judges, that ten and twelve guineas have been offered for rams of the first cross with Merino ewes. Lord Western, the celebrated breeder of Merino sheep, has, we are informed, lately turned his attention to this improved breed of sheep, and is now crossing them with Merinos, with the view to the production of a long and strong wool. The sheep, when we saw them, were being conveyed to New England, where Messrs. Denne have purchased several thousand sheep, together with a right of station. We congratulate the inhabitants of that district upon having received such a valuable addition to their number, as gentlemen of the knowledge of sheep, that Messrs. Denne must be.

ON THE PLOUGH, IN ANSWER TO MR. SMART.

TO THE EDITOR OF THE MARK LANE EXPRESS.

Sir, — In your journal of the 29th of June, appears an essay on the power and construction of ploughs by one William Smart, of Rainham, Kent, a farmer; and the conclusion at which Mr. Smart arrives after a long A. B. C. and D. theorem, after kindly informing Mr. Pusey that not one of the nine ploughs, employed in his late experiment, is formed upon a true mechanical principle, and amongst other things, that the number of horses required to work a plough, is a mere matter of indifference—the conclusion I say, at which Mr. Smart arrives is, that his own dear four-horsed, two-manned, turn-wrist plough, is far superior to any other yet invented, it being, in his opinion, constructed on truer mechanical principles.

Now Sir, I am but a plain farmer, and unwilling to follow your learned correspondent when he talks of curvatures of lines, angles of inclination, and so forth. Considering as I do, that if an agricultural implement is invented, be it plough, be it roll, harrow, drill, or any thing else, and it is proved to do its work at a cheaper rate, and at the same time, quite as effectively as the more clumsy instrument it is intended to succeed, it is a matter of perfect indifference, upon what principle it is constructed, whether, with regard to the plough, the angle of inclination is $14\frac{1}{2}$ degrees, or 19 degrees. Let me not however be supposed to admit, that either the two-horse swing, or wheel-plough, is formed upon any but true mechanical principles. But Sir, I think it would be more useful, that the respective merits of the two ploughs should be proved in practice, than discussed in theory.

Mr. Smart, after proceeding at some length to prove the superiority of his plough as a work of art, as being constructed on truer mechanical principles, raises another objection to the fixed wrist-ploughs.

"Should it prove," says Mr. Smart, "that the form of the said instrument is less objectionable than is now supposed, yet the wrist or mould boards being fixed are calculated to limit the usefulness thereof; a plough with sliding wrists, removable at pleasure being preferable. I am willing to admit, under certain circumstances, this objection to be good. Where the country is hilly, and side banks have to be ploughed, the land must necessarily be turned all one way which cannot well be done with a fixed wrist; but a plough has within these few years been made similar in every respect to the common Suff-

folk and Norfolk ploughs, except that it has shifting wrists or mould-boards, which are so nicely arranged that they can be adjusted with ease at the ends of the furrows without requiring the stoppage of the horses, thus enabling the ploughman to turn his land all one way, and thus surmounting the difficulty raised by Mr. Smart in his second objection.

With regard to the ease with which a Kent turn-wrist plough may be converted into an instrument for broadsharing, and on which Mr. Smart lays so much stress, the same receipt is as applicable to the one plough as the other; the breast, or mould-board, of our Suffolk plough is easily removed, and a share of any construction may be placed in room of the one more commonly used.

But Sir, this broadsharing is an operation with which we are little acquainted in this county, except from hearing it talked of as practised in Kent; preferring as we do, to destroy weeds in their infancy, to allowing them to grow and seed amongst the corn, in which latter case, the operation of broadsharing certainly becomes necessary.

I will endeavour now Sir, to meet another objection raised by Mr. Smart, to the two-horse fixed wrist-plough. Mr. S. proceeds. "The Kent, or turn-wrist plough, has several advantages over one with a fixed mould-board in laying the land level, instead of being thrown into ridges, which on dry land can be of no use."

Now Sir, if Mr. Smart insists, that laying the land in ridges when dry, is worse than useless, he will surely allow, that it must be most useful when the land is wet, and in allowing this, he must acknowledge an advantage which our fixed wrist plough has over the turn-wrist. But Sir, I do not allow that the turn-wrist can boast the advantage over the fixed wrist that Mr. Smart mentions. In the first place if your land is dry, which Mr. S. assumes, your ridges may be made any size, and secondly, the furrows between the ridges may, by harrowing, be entirely obliterated, as is the case on the farm in the occupation of Mr. Smith of Deanston, to whom agriculturists are so much indebted for the invention of the subsoil plough, &c.

Mr. Smart next alludes to the time that is lost in turning our ploughs, adducing, as an example, that in ploughing on ridges four rods wide, the time lost in turning will be one day in twenty. Now Sir, as we are comparing the merits of two ploughs, pray let us be just, if it is only for the sake of undermining a prejudice. I am willing to grant to Mr. Smart, that one day in twenty is lost in turning our ploughs at the ends of the furrows, but pray what proportion does this bear to the time lost in turning the four horse turn-wrist plough? In my note book, I find, amongst others, the following remarks made by me during a residence of three years on a farm of 700 acres of land in Kent, and upon the authority of the occupier of that land, a gentleman who has for thirty years farmed in that county. "I find here in Kent, that on a ploughman going to work for his eight hours, he has one hour allowed for turning his plough at the ends &c., so that in point of fact he ploughs but seven hours." Now Sir, one hour per day, is six hours per week, so that in turning this turn-wrist plough, one day's work all but one hour, is lost in a week, or nearly three times as much as in turning our Suffolk plough. So much for Mr. Smart's objection to our plough, on account of the time lost in turning it.

To Mr. Smart's concluding remark I most willingly agree, viz., that if a turn-wrist plough can be produced, which requires no greater power to propel it than others, and which performs its work equally well, it is equally worthy of notice, as the two horse

fixed-wrist plough. But Sir, until such a turn-wrist plough is produced, I maintain that it is an implement unworthy of notice, except for the purpose of showing its inferiority to more recent inventions; and Sir, until such a plough is produced, I assure Mr. Smart he cannot do better than adopt in the mean time, our improved iron ploughs, which are capable of ploughing up every thing but a prejudice, and which he will find upon trial, to be constructed on quite as true mechanical principles as the turn-wrist.

I am Sir, your obedient servant,

DANDY SHARWOOD.

Blairhall, July 3rd.

ON THE CULTURE OF TURNIPS.

TO THE EDITOR OF THE DUMFRIES-SHIRE AND GALLOWAY HERALD.

SIR,—In my last, I stated the mode of turnip sowing which, on clay soils, general principles led me to adopt, and which successful experience has led me to continue. On light free soils this method is less proper; as in them seed not only may be buried deeper, and lighter rolled, but it really requires a deeper bed to give the plants a sufficient hold of the ground, before thinning commence.

On heavy clay soils, few attentive farmers will grow turnips to be eat off by sheep. Yet a neighbour of mine has done this from year to year, and his succeeding crops of barley have been scarcely worth reaping. In 1836, he had the best crop of turnips I saw that season. His field next spring was poached by sheep, and his barley was the worst I ever saw; it was more fitted for the shears than for the sickle.

Barley needs a warm and free soil, as well as much sunshine to bring it to perfection; but on its nature, culture, and deterioration, I may offer a few remarks soon, if the present are taken in good part.

As adhesive soils are not naturally fitted for turnips, and are injured by sheep, turnips on them can, with advantage, be cultivated only to the extent required for home feeding; and keeping this in view, the farmer will find the additional trouble occasioned by the following plan stated in your last amply compensated by the superiority of his crop.

Indeed, with skill and attention, the cultivator of the stiffer soils may feed off cattle to a considerable extent, and avail himself of the steam navigation to Liverpool; while his neighbours, on light soils, may give themselves with equal advantage to the feeding of "turnip sheep."

The farmers in this district are a shrewd intelligent class, and rank high as turnip growers; but the rage for feeding-off with sheep has drawn not a few of them into serious losses.

The great supply of sheep pasture on the high grounds of this county, the large proportion of light soils in its low grounds, and the local convenience it affords for English sheep markets—all combine to point out Dumfries-shire as fitted by nature for sheep-feeding, to a large extent; and the little trouble which feeding-off turnips with sheep gives to the farmer, compared with the tedious labour and close attention imposed on him by stall or home-stead feeding, makes him partial to the former, even when he is crossing nature and injuring his future crops by the act.

It is a remarkable fact, that the soils fitted for "turnip sheep" are the very soils fitted also for bone manure; while the soils injured by sheep

treading in winter or spring are the soils fitted only for farm-yard dung. This fact alone might teach the farmer that he ought to take home the turnips grown on such soils, and send them back to his field in the shape of rich dung. It is well known that one cartful of dung, when turnips are very freely given, is better than two cartful where the dung is formed from straw alone. Thus nature, if allowed to act, makes full provision for her wants. I have digressed from my chief object, which was to make some remarks respecting the turnip fly.

A writer in the *Entomological Magazine*, some years ago, concluded from his experiments that the turnip fly does not come from other plants, is not bred in the soils from which the turnips grow, but arises from eggs deposited on the seeds themselves. By aid of a lens, he observed from one to five white specks on most of the seeds. These he supposed to be the nidus of eggs; and he escaped the fly entirely by steeping the seed for three hours in pretty strong brine. I have examined many seeds of the Swedish kind with a microscope, which makes them appear as large as plums, and observed many small white specks on their surface; but these I took for minute particles of dust, and suspect that, if the insect deposits her eggs at all on the seed, she buries them in its interior.

Many steeps have been in use, but none of them has been attended with even general success; and the particular successful instances recorded may be ascribed more to the soil, manure, season, and weather, than to the power of the steep in killing the animalculæ. Where any steep is beneficial, it must be chiefly by its hastening the growth of the embryo plant, it cannot be by killing the eggs of insects; for all the steeps recommended are either antiseptics (which would preserve the eggs instead of killing them), or are promoters of vegetation.

It is quite possible that the larvæ of insects may be killed by drinking a solution of an alkaline or a metallic salt. We know that white lead thus kills the *infusoria*; and the manure used for turnips may often contain impregnations fatal to the larvæ of the "fly."

But one fact seems to render the above writer's theory very questionable: If, with him, we suppose that the fly arises from eggs deposited on the seed, we must infer that the number of eggs and beetles must increase with the number of seeds sown; or rather, that the insects must at least be double the number of the seeds. Hence, if one fly eat the seed-blade of only one plant, the whole of the plants would be destroyed, however much seed was sown. But this is amply disproved by facts. Mr. Coke of Holkham, Mr. Berry, and various eminent agriculturists, have been taught, by many years' experience, that *thick* sowing is the best preservation from the fly.

Two years ago, I sowed by the hand two drills with the seed of Swedes and made my servant sow the rest of the plot with the same seed put in by the machine. He gave much less seed than I did. My two drills gave an excellent thick crop; his shewed a uniform but *thin* plant. The fly soon took almost every blade of the machine-sown drills; but its injury was not perceptible on the other two. These afforded a large supply for transplanting, while the rest of the drills had all to be sown again.

I have never found any inconvenience from the plants being too thick. The thinning process has always been easy and safe.

I am, Sir, yours truly,

G.

LETTER ON BEES.

SHOWING HOW TO TAKE THE HONEY FROM THEM, AND YET TO PRESERVE THEM.

(FROM THE SALOPIAN JOURNAL OF OCT. 30TH, 1839.)

MR. EDITOR,—I fear that most persons who keep bees have already proceeded "*to put them down*," or as it is termed in some counties, to "*take them up*"—that is, to destroy them with brimstone. Should there be any, however, who yet possess weak stocks, and who are in doubt whether, with the provision which they have, they will live through the winter, allow me to advise them to take the comb and honey from such stocks, and transfer the bees to other hives. This plan will be attended, in the first place, with an immediate gain of honey, it being an ascertained fact that two stocks of bees when put together in one hive, will not consume much above *one half* the quantity of honey which they would consume if kept separate. By keeping two stocks of bees therefore separate, if one hive will contain them both, persons are actually wasting honey. Another advantage from the plan is, that if two or three stocks of bees are put together in one hive there will be earlier and stronger swarms when the season for swarming arrives. The consequence of this I need not say will be the amassing a much larger quantity of honey in the following summer. This will be the result in a common way. If, however, the following season turn out to be a particularly good honey season, there will be so many additional thousands of bees to collect that which would have otherwise been lost if the bees were destroyed. Bees only live one year, and those remaining in a hive in the autumn are always such as were bred during the summer, and intended to do all the work of the succeeding spring; to destroy them, therefore, is a wanton and unnecessary waste of property.

Perhaps some persons may smile at the idea of taking the honey without killing the bees, and declare that it is impossible. In reply I assert that it is not only possible, but *perfectly easy*, and attended with as little—if not indeed often with less—trouble than killing them. The operation is performed in a very few minutes;* and, if done with care, scarcely a single bee need be lost. Within these two or three weeks past I have shown some cottagers how to do it, who are really delighted with the plan, seeing how perfectly practicable and easy it is. I have taken away the honey and comb from fourteen hives, and transferred the bees to other hives; and the bees thus united, are as quiet and peaceable as if they had always been together.

The plan I have adopted is the following:—at the proper season, that is in autumn, before they were fully ripe—I picked up three or four fuzzi or puff balls (a large kind of fungus or mushroom growing in the meadows), these I compressed a little and then had them thoroughly dried in an oven, after the bread had been taken out, and I kept them in a dry state till I wanted them. I had also a round box made of thick tin, (without any solder,) with a top full of holes to take off; the diameter of the box is about two inches, and its depth about an inch and a half; the top is about an inch and a half in height, ending in a point; at the bottom of

the box are three holes. The box and fuzz ball being ready I took an empty hive—as nearly as possible of the same size as that from which I intended to take the bees—turned it bottom upwards and placed it in a pail. I then cut a stick sharp at one end, and fixed the other end in the middle hole at the bottom of the tin box; having done this, I cut off a piece of the fuzz-ball, about double the size of a hen's egg, lighted it in the fire, placed it in the box, put on the lid, fixed the sharp end of the stick in the bottom of the empty hive, as it stood in the pail, and then immediately put upon the empty hive the hive from which I intended to take the bees, placing a wet cloth round the two hives (where they joined) to prevent any smoke from getting out. In about a minute the bees began to drop, just as if peas or heavy drops of rain were falling; soon after this, I tapped the top of the full hive several times to make them fall faster; in a short time the dropping ceased. I then took off the cloth, and found all the bees lying still and quiet in the bottom hive, except a few which remained sticking to the combs or in the cells. I then turned out the bees upon the table, found the Queen, and placed her in safe keeping under a glass, (supplying her afterwards with a little honey on a small piece of comb.) Having so done, I swept the bees back into the empty hive with a feather, and placed the hive again in the pail as before. I then sprinkled them freely with a thick syrup made of sugar and ale boiled a minute or two, and placed upon the empty hive containing the stupified bees the other hive with which I intended to unite them, pinning a cloth round them so close as to prevent any opening for a bee to escape. I next put them by in a place where no accident could happen to them by being thrown down, &c., and let them stand till about ten o'clock the following night, or the night after the following night, when I brought them quietly out, unpinned the cloth, and placed the top hive immediately on the spot from whence it had been before taken, and left them; this completed the operation, and it has answered in all the fourteen cases I have referred to. In three instances I have put two stocks of bees to a third, thus having in a single hive three quantities of bees.

It is better, I think, (though I do not say that it is absolutely necessary,) to take the Queen away; it avoids all risk of disagreement, and she is easily found by looking out sharply; she is longer, more taper, and has shorter wings than common bees. I generally find her by stirring the bees about with a quill, if she cannot be observed at once. If persons choose to sacrifice the few bees which remain in the combs they can, and this will shorten the operation; but there is generally time enough to take them all out before the stupified bees return to activity. It is important not to forget to sprinkle the stupified bees with the syrup of ale and sugar, as its scent attracts the bees down from the full hive; smelling that, they will soon go down and commence licking the sprinkled bees clean. They thus get intermingled, and afterwards all go quietly up to the top hive, as if they had always been one family.

If any person choose to try the plan, the puff balls will do, if dried, as I have before pointed out. If, however, none can be obtained, a substitute may be found described in *Taylor's Book-keeper's Manual*,* price 4s., published by Groombridge,

* It may be done any time during the day if the hives are only stopped up over night.

* Taylor recommends, in the absence of the fungus or blind-ball, common blotting paper, several times.

London. It is better to preserve the captured Queen as long as she will live, in case of any accident to the other; she generally lives about three or four days. When I teach a cottager or farmer the plan, I extract a promise that he will again teach it to others. The month of September is the best time of the year.

Should these observations prove the means of leading any persons interested in bees to save their own, and of teaching so useful a plan to cottagers, I shall be most happy.

ALIQUIS.

October 21st, 1839.

YORKSHIRE AGRICULTURAL SOCIETY.

The third annual meeting of this interesting Society took place at Northallerton on Wednesday, Aug. 5. In consequence of the extent and importance of the agricultural district around the town of Northallerton, a most excellent show of stock was anticipated, and the greatest interest was excited.

For some months the District Committee, with the Rev. J. Monson as the chairman, and M. M. Milburn, Esq., as the secretary, have been very indefatigable in making the necessary arrangements, and it is only due to them to state that they displayed a laudable anxiety to accommodate all parties to the utmost extent.

Earl Spencer arrived a few days previous to the exhibition, at the residence of Sir Samuel Crompton, Bart., of Woodend, and during the early part of Tuesday, a great number of gentlemen arrived at the Red Lion Inn. The various other excellent inns in the town also began to be busied with visitors, and on the road great quantities of stock were observed progressing towards Northallerton. Many of the more valuable stock were brought in caravans, and the whole town presented a gay and animated appearance.

The central committee and the district committee united on Tuesday morning, and were engaged in deliberations for a number of hours. They were attended by Charles Howard, Esq., the general secretary, and M. M. Milburn, Esq., the district secretary. The noble chairman, Earl Spencer, presided, and by his great agricultural experience rendered important services to the joint committees.

DINNER OF THE UNITED COMMITTEES.

On Tuesday afternoon a party of about 100 gentlemen sat down to dinner at the Golden Lion Hotel; the Earl Spencer was in the chair, and the Rev. J. Monson acted as vice-president. The following were among the company:—Col. Graham, W. Armitage, Esq., T. Hutton, Esq., Rev. E. Wyvill, M. Wyvill, Esq., T. D. Bland, Esq., S. Wiley, Esq., W. F. Paley, Esq., H. Vansittart, Esq.,

W. B. Wrightson, Esq., M.P., R. F. Shawe, Esq., Count De Gourcey, H. S. Thompson, Esq., Sir J. Johnstone, Bart., J. W. Childers, Esq., M.P., C. Howard, Esq., M. Milburn, Esq., C. Tancred, Esq., J. Booth, Esq., J. C. Maynard, Esq., T. S. Walker, Esq., R. M. Jaques, Esq., Leo. Severs, Esq., W. Lex, Esq., J. Douthwaite, Esq., W. Mauleverer, Esq., J. Harland, Esq., J. T. Wray, Esq., H. Glaisster, Esq., T. Bradley, Esq., T. Scott, Esq., T. Fowle, Esq., W. Fowle, Esq., J. Favell, Esq., R. Haynes, Esq., Rev. T. Monson, J. Roccliffe, Esq., A. Maynard, Esq., E. Clarke, Esq., T. Masterman, Esq., H. Hirst, Esq., H. Cholmeley, Esq., Rev. W. Lockwood, Rev. J. Higginson, W. Rutson, Esq., Rev. John Waites, Major Healey, Rev. P. Ewart, M. Stappylton, Esq., T. Charge, Esq., Sir R. Bateson, Bart., &c. &c. The dinner was served up with great style, and the repast being concluded,

The CHAIRMAN suggested that on the present occasion cheers should be dispensed with. He then proposed in succession the following toasts:—"The Queen," "Prince Albert," "The Queen Dowager and the rest of the Royal Family."

The noble CHAIRMAN said the next toast was one which he hoped he might be allowed to preface by a few observations. It is "May we have a good show to-morrow, and fine weather." With respect to a good show he felt confident that they should have a good one—the number of carriages he had seen, the number he had heard of being on the road, and the extent of the entries, satisfied him that this would be one of the most magnificent shows which had ever been seen in this country. (*Hear.*) There was one point on which he might apprehend some drawback, the disease which was known to prevail among cattle might make some persons afraid of bringing their stock. This was the only chance of the show being in any way injured. (*Hear.*) He recommended that on the present day they should speak on practical subjects; as on the morrow from the extent of the building and from other circumstances, it would be impossible to discuss such subjects. Having stated that the only apprehension which existed in his mind of any deterioration of the show was in consequence of epidemic, he might detail to them what his practical experience of this disease had been. (*Hear.*) They were aware that he had had a good deal of practical experience in the breeding and grazing of stock, having two large farms—one of which was for breeding to a considerable extent, and the other for grazing. On both these farms, he had escaped this disease. It would be absurd to say how he had done so, but he would tell them what he had done to prevent it. When he first heard of the disease, he made inquiry respecting it, and formed an opinion that it was a contagious disease, but not infectious. If the disease was communicated by breathing there would be no preventing it by separating stock; but if it was communicated by the touch then a strict quarantine might prevent it. Acting upon that opinion he put a strict quarantine in force on his farm; he brushed the gates, and kept the cattle from communicating with cattle on the roads. Being a grazier he of course had to buy stock in; and as he purchased each lot he put them under 14 days' quarantine; one of those lots was found to be afflicted with the disease, but having had them separated from his general stock, he prevented any spread of the disease. Another precaution he took was to place a lump of rock salt in every field, which it is well known cattle are fond of. With these precautions he had avoided the disease, although it had existed all round him.

P

folded, and a small portion of tobacco leaf placed between the fold; this is to be saturated in a solution of nitre, and dried before the fire. The paper, when divided into small pieces will readily light, and produce smoke abundantly. A small tea-spoonful of the nitre to a pint of water will be sufficient. There is a cheap tract called the Conservative Beekeeper, admirably adapted for distribution; it contains much valuable information of bees, and may be obtained of booksellers for 2d. A tin box as described above may be made for 4d.

(*Applause.*) This disease he had expressed his opinion was contagious but not infectious—the reason why he thought it was not infectious was, that a farmer in Northamptonshire, had the disease introduced into his farm, and that those cattle which communicated with them by the touch took the disease, whilst those which were prevented from coming into such close contact, entirely escaped. (*Applause.*) He had mentioned these circumstances, because the precautions he had taken were unattended with expense and required little trouble. Therefore he would recommend them to try these precautions; he would not say that it would ensure them, but he had avoided it, and he thought it would be well to follow the example. The Royal English Agricultural Society had taken the opinion of many scientific men as to the treatment of the disease, and had circulated papers containing those opinions. The farmers of the country generally were averse to follow these regulations; he would, however, recommend gentlemen to follow the recommendations of men of high authority rather than resort to quackery.

H. S. THOMPSON, Esq., said that he always had rock-salt in his fields, but yesterday two of his cattle broke out with the disease.

The Hon. Mr. NUGENT said that in Warwickshire this disease had broken out among his cattle, especially the one year and a-half and two year olds. He had placed them in separate pens, he then hung up a piece of rock-salt on one side and chalk on the other; which of these had been beneficial he did not know, but now these cattle were as sound as any other stock.

R. DENISON, Esq., asked whether any gentleman had had stock affected in the hoof—the disease sometimes appeared in the hoof, and sometimes in the mouth.

The CHAIRMAN said yes—some of his had been lame. They were treated according to the direction of the English Agricultural Society.

WM. F. PALEY, Esq., said he had had his cattle in a park, with no communication with any other animals since May, yet, strange to say, the disease had appeared among them.

The CHAIRMAN said he would now propose another toast—the Judges of the Cattle. It had usually been his task to thank them for the trouble they had taken, and to express his thanks for their past services. On the present occasion he would have to speak in a different tone—he hoped they would all have a great deal of trouble, in consequence of the excellent competition with the stock. (*Applause.*) They were much obliged to gentlemen who had come from a great distance to discharge a disagreeable office, one in which, however, he was sure that the committee would readily support them. He gave “The Judges of the cattle and Sheep.”

SIR JOHN JOHNSTONE said he rose to propose a toast on the present occasion, the subject of which he was convinced need only be named to meet with enthusiasm. It would be improper in him, for two reasons, to make any enlarged observations—1st, the presence of the noble individual to whom he referred; and 2nd, that no person was in the company who did not appreciate the services of the noble lord in his management and direction of their infant institution, by which the society had attained its respectable, nay, more than respectable—its gratifying position. (*Applause.*) He would give the health of their noble chairman, and, as they wished to get as much out of him as possible, he would ask what was his

opinion of the wheat crop this year? (The toast was given with three times three cheers.)

The Noble CHAIRMAN said he felt extremely obliged for the honour done him. He was sorry they had so soon broken through the rule which he had laid down, although it was very flattering that drinking his health had been the occasion of it. If any services of his had tended to the success of the society, it gave him the greatest gratification. He believed that the effect of a society like this in the great county of York would confer immense benefit on England. (*Applause.*) From his residence out of Yorkshire, and his slight connexion with it as regarded property (although his connexions with valued friends were as great as any man could desire), he felt a difficulty in accepting the office of president of the society. Being, however, satisfied, that the society would be of advantage, and having had some experience, he accepted the office; and, although he feared he had not done much service, he had rendered what little assistance he could. (*Applause.*) He had been asked what were his opinions respecting the wheat crops. He was a practical farmer to a considerable extent, but he had been engaged principally in grazing stock; it was, however, impossible for a person engaged in farming not to keep his eyes about him, and see what the crops were. He was afraid the crops were not good this year. He feared that the strong lands would fail to a great degree. In strips of England the crops might be good, but he feared they would fail in many important districts. This was mainly owing to the bad seed time. There was, he believed, a greater breadth of wheat sown than usual, but nevertheless he feared the crop would not be large. If they were blessed with fine weather from this time till the end of harvest, the evil might be remedied to a great degree. He thought it would be well if gentlemen, coming from distant parts, would communicate what their opinions were, which would be a great advantage to the meeting. (*Hear.*) There were also other topics which might be discussed with benefit: there was one subject on which this society had devoted much attention—whether it was desirable to have a model farm, and to establish a school of agriculture. If such a school could be established, he believed it would be a great advantage.

R. DENISON, Esq., said he had been travelling in the south of England, and had taken a good deal of notice of the crops between York and London. He was sorry to say that throughout the whole district, by way of Sheffield and Birmingham, he did not see one good wheat crop.

H. S. THOMPSON, Esq., said he had been in Somersetshire, where he had seen many very excellent crops.

J. W. CHILDERS, Esq., said that he had made a variety of inquiries of farmers as to the state of the crops, and their answers were—“The crops are generally bad, but ours are good.” Now as this was a general answer, he thought the general crop was not so bad as was supposed. His inquiries had extended to Hampshire, Cambridgeshire, and his own district, and he did not think the evil was so great as was supposed. He believed it was admitted that the crops in the north of Europe were very similar: and the prices of corn in France indicated that the crops of that country were good. He would mention one thing, which was very fanciful, but which had made some impression on his mind. It was that our series of bad years were ushered in by a bad year in America. Now last

year the Americans had a good season; so if their cycle of bad seasons is expired, it might be anticipated that this year England's cycle of bad seasons had terminated.

J. BAKER, Esq., of Nassau Grange, near Leeds, said as they were invited to communicate any information in their possession, he might mention that he received a letter three or four days ago from his brother, who is a considerable farmer in Norfolk—a county well known for the production of corn—in which he stated that corn was above an average crop, and that he intended to commence harvest as to-morrow, for wheat and oats. In coming from Ripon to that meeting, he had seen some splendid crops of corn, and indeed he had seen no bad crops. (*Applause.*)

W. MAULEVERER, Esq., said he was glad to find that the propriety of forming an agricultural school had engaged the attention of the committee. During his recent absence in France, he had visited the Royal Agricultural Institution, about twenty miles from Paris. This establishment was founded in 1829, by Charles X.; and its results had been a material and positive benefit with regard to agriculture. (*Applause.*) There was also an experimental farm attached to the institution; it was established in joint-stock shares, and had been the means of enabling many young men to obtain an advantageous livelihood, who would otherwise have been in obscurity and indigence. He then read some extracts from the prospectus to this institute, and observed, that if something of the same nature was attempted in shares of 10*l.*, 15*l.*, or 20*l.*, he had no doubt a sufficient sum would be speedily raised, and that the institution would be supported. He then observed, that many farmers were so ignorant as not to be able to write their own names, and it was impossible that landlords could prudently let their farms on long leases whilst farmers continued in their present ignorant state.

R. DENISON, Esq., said he agreed with the preceding speaker, as to the advantages which would result from establishing an agricultural school; but at the same time he was anxious to rescue the farmers from the stigma which had been cast upon them by Mr. Mauleverer. (*Hear.*) He believed they were a highly respectable and valuable class of men, who were generally anxious to avail themselves of all the improvements made in agriculture. This, he contended, was evinced by 1,200 farmers having joined that association, and 1,000 farmers were united with the society at Beverley.

Mr. MAULEVERER explained, that he had no wish to cast a stigma on the farmers, whom he highly respected, and who were more to be pitied than censured for want of education.

The Rev. P. EWART corroborated the general outline of Mr. Mauleverer, as to the state of the farmers.

The CHAIRMAN said he had some doubts on the advantage of an experimental farm, but he had no doubt whatever of a school of agriculture, provided the difficulties could be overcome in establishing it. With reference to an experimental farm he had a greater doubt, because it could be experimental only for that farm. His own opinion was, that a greater improvement might be effected in agriculture by the assistance of intelligent farmers than by the establishment of experimental farms. (*Hear.*) Some observations had been made on the intelligence and education of farmers: few persons possessed a greater acquaintance with farmers in various parts of England than himself, and although some were extremely ignorant, obstinate, and prejudiced, yet the majority of them were intelligent, and anxious for the improvement of agriculture. He then gave—"The Judges of the other classes of live stock."

A gentleman made some observations on draining, recommending the use of the spirit level.

The CHAIRMAN said, the next toast he had to propose he was sure would be drunk with great satisfac-

tion from his knowledge of the health which he was about to propose. He was a gentleman who had acted as the chairman of their local committee at this meeting, and had been most active, zealous and able in performing the business connected with this exhibition. He gave "The Rev. J. Monson." (*Applause.*)

The Rev. J. MONSON returned his grateful acknowledgements. So much had been said and well said on general topics, that he should content himself with stating that societies of this description were most important and beneficial in their operations.

The CHAIRMAN alluded to the importance of the Highland Society and the great improvement which it had produced in the agriculture of Scotland; he then observed that he trusted the principle on which agricultural societies were formed, to combine scientific improvement with the exhibition of stock would be beneficial. With regard to the veterinary art, with the exception of the treatment of horses, everything was in a most backward state. He was happy, however, to say, that the English Agricultural Society had allied itself to the Veterinary College in London, and secured the delivery of lectures on the treatment of cattle. He could assure them that any gentleman who had cattle afflicted with any disease which the local farriers could not comprehend, on sending up a statement of the symptoms to London, it would receive every attention. He concluded by giving—"The Highland Society."

A gentleman connected with the agriculture of Scotland, returned thanks.

The CHAIRMAN said the next toast he had to propose was connected with the agriculture of Ireland. To a certain extent Ireland was their rival, but such a rivalry he was glad to see. The Irish people he knew were anxious to improve their stock, and he hoped that next year they would have a good contest at Liverpool. He gave "The agriculture of Ireland."

Sir R. BATESON returned thanks, observing that for 13 years they had had a model farm and school in the North of Ireland, which had been attended with very beneficial results. They had now 72 pupils on the books, and between three and four hundred pupils had left the school, from all of whom they had received favourable accounts of their progress in the world. He detailed at some length the satisfactory state of the school, and in conclusion returned thanks for the interest taken in Irish affairs by the Yorkshire Society.

The CHAIRMAN then proposed the last toast of the evening, which he considered the most interesting of all, uniting as it did, the three great interests. He begged to give "Agriculture, Manufactures, and Commerce." (*Hear.*)

The Noble CHAIRMAN then retired, and was followed by the rest of the company, a little before eight o'clock.

THE EXHIBITION.

On Wednesday Northallerton presented such a bustling appearance, as was probably never before known in that town. At the various inn-yards lines of horses might be seen standing by fifties together, and the houses were crowded with guests, whilst the streets were absolutely blocked with carriages. The weather was extremely fine, which increased the attractions of the day.

The fields of exhibition were situate on the south of the Court House, and were extremely well adapted for their purpose. They contained about eight acres; the field nearest to the Court House was for the cattle, sheep, pigs, poultry, and seeds. The cattle extended round three sides; the sheep were in the centre, and the poultry and pigs were on the low-side. The horses and implements were in the field nearest to the Thirsk road, each field having a ready communication with the other. Convenient pens, &c. were erected at the sole expense and under the direction of John Hutton, Esq., of Sober Hill, to whose exertions the society is much indebted, as also to Mr. Monson, Mr. Rutson, and other most efficient members of the local committee.

Soon after seven o'clock on Tuesday the judges commenced their labours, which were of an arduous and difficult nature from the superiority of the stock exhibited, and the number of competitors in the various classes.

The following were the amounts of premiums offered:—Short-horned cattle, 245*l.*; Leicester sheep, 95*l.*; pigs, 35*l.*; horses, 145*l.*; shepherd, 5*l.*; implements, grains, &c., 55*l.*; drainage, 10*l.*; reports, 45*l.*; poultry, 10*l.*; total sum offered for prizes, Six hundred and forty-five pounds. This noble sum was ably contended for in the various classes. In short-horned cattle there was probably no exhibition ever produced in England equal to it, either for number or beauty of symmetry. This we have the authority of many excellent judges to declare was the case. The display of sheep, although not great, excited the admiration of the agriculturists, and the pigs were remarkably fine animals. The horses attracted great attention; the entire horses were very numerous, and many of them presented many good points. The brood mares and young horses were also greatly admired.

The members were admitted to the ground at nine o'clock, and at ten non-members with half-crown tickets were allowed access to the ground. From the excellent arrangements not the least confusion took place, although the roads leading to the exhibition presented one moving mass of people. At twelve a more extensive admission was made of visitors at one shilling each, and probably altogether there were 7000 people visited the exhibition. An effective body of police were stationed in the field to preserve order, but the good conduct of the populace rendered their assistance almost unnecessary. The receipts of the field, we understand, exceeded 400*l.*, and a considerable number of new members were admitted.

The following gentlemen acted as

THE JUDGES.

FOR HORSES.—Mr. Robert Smith, of Givendale; Mr. James Harrison, of Low Fields; Mr. James Dickinson, of London, horse dealer.

FOR CATTLE.—Mr. John Dawson, Grenant, Flintshire; Mr. C. Angus, Newick, Driffield; Mr. John Hunt, Thormington, Northumberland.

FOR SHEEP AND PIGS.—Mr. Robert Foster, of Southburn, near Driffield; Mr. William Torr, Jun., Riby, Lincolnshire; Mr. James Jobson, Newton.

FOR POULTRY.—Harry Wermald, Esq., of Sawley Hall, near Ripon.

FOR IMPLEMENTS.—Mr. John Young M'Vicar, Kelfield, Escrick; Mr. Robert James Wiley, Brandsby, York; Mr. Bryan Tibbett, Woodend, Thirsk.

These gentlemen devoted much careful attention to the duties of their office.

The following were the Premiums awarded:—

SHORT-HORNED CATTLE.

CLASS 1.—For the best bull of any age, 30*l.* First prize awarded to F. H. Fawkes, Esq., of Farnley Hall, for his bull, Sir Thomas Fairfax, calved in April, 1837. Second, 10*l.*, Mr. Wm. Raine, for The Colonel, calved in January, 1838.

[The bull which gained the first prize need not be retained in Yorkshire, but shall serve in any part of the United Kingdom, if required, the first thirty cows sent to him, within nine months from the day of the show, by members, at a sum not exceeding two sovereigns each. If the owner refuses to comply with these terms, he shall forfeit fifty pounds to the society.]

CLASS 2.—For the best two-year-old bull, 20*l.*; first, Mr. Wm. Raine, for The Colonel. Second, 10*l.*, Messrs. Chilton and Harrison, for Prince Albert, calved April, 1838.

CLASS 3.—For the best yearling bull, 20*l.*; first, Mr. Lax, for his Bob Shafto, calved in January, 1839. Second, 10*l.*, Mr. Lax, for the brother to the above, calved last January.

CLASS 4.—For the best bull calf, 10*l.*; first, Mr. Hutton Rowe, for his Duke of Wellington, calved last

January. Second, 5*l.*, Mr. Booth, for his Leonard, calved in January last.

CLASS 5.—For the best cow of any age, in calf or milk, 20*l.*; first, Mr. T. Bates, for his Oxford, calved in 1834. Second, 10*l.*, Mr. J. Booth, for his Yorkshire Jenny, calved March 11, 1836.

CLASS 6.—For the best three-year-old cow, in calf or milk, 15*l.*; first, Mr. J. Booth, for his Bracelet, calved February 12, 1837. Second, 5*l.*, Rev. J. Higginson, for his Daisy, calved in February, 1837.

CLASS 7.—For the best two-year-old heifer, in calf, 15*l.*; first, Rev. J. Higginson, for his Amazon, calved in October, 1837. Second, 5*l.*, Earl of Zetland, for his Virginia, calved in March, 1838.

CLASS 8.—For the best yearling heifer, 10*l.*; first, Mr. W. Raine, for his Alexandria, calved in February, 1829. Second, 5*l.*, Mr. John Booth, for his Mantallin, calved in February, 1839.

CLASS 9.—For the best heifer calf, 10*l.*; first, Mr. Wm. Raine, for his Hannah, calved in January, 1840. Second, 5*l.*, Rev. J. Higginson, for his Lily, by Box, calved January 15, 1840.

CLASS 10.—For the best fat Ox, 15*l.*; Mr. Wiley, for his ox, calved in July, 1835.

CLASS 11.—For the best fat cow or heifer, 15*l.*; Mr. J. Clarke, for his roan cow, calved in May, 1836.

LEICESTER SHEEP.

CLASS 12.—For the best shearing ram, 20*l.*; first, Mr. Garforth. Second, 10*l.*, Mr. Kendall.

CLASS 13.—For the best ram of any age, 15*l.*; first, Col. Croft; second, 7*l.*, Mr. Borton.

CLASS 14.—For the best pen of five ewes, 10*l.*; first, Mr. Allen; second, 5*l.*, Mr. Robinson.

CLASS 15.—For the best pen of five shearing wethers, 10*l.*; first, Mr. Allen. Second, 5*l.*, Mr. Foster.

CLASS 16.—For the best pen of five shearing gimmers, 10*l.*; first Mr. Allen. Second, 5*l.*, Mr. Fawcitt.

PIGS.

CLASS 17.—For the best boar, large breed, 5*l.*; first, the Duke of Leeds; second, 2*l.*, Mr. Brael.

CLASS 18.—For the best sow, large breed, in pig or milk, 5*l.*; first, Rev. J. Higginson; second, 2*l.*, Rev. C. Smith.

CLASS 19.—For the best boar, small breed, 5*l.*; first, Rev. J. Higginson; second, 2*l.*, Mr. Parrington.

CLASS 20.—For the best sow, small breed, in pig or milk, 5*l.*; first, Rev. J. Higginson; second, 2*l.*, Mr. Meek.

CLASS 21.—For the best three store pigs, from four to nine months old, 5*l.*, to Mr. Jordison.—No competition.

HORSES.

CLASS 22.—For the best stallion for hunters, 20*l.*; first, Mr. Foston, for Young President, aged; second, 10*l.*, Mr. Ferguson's Figaro. Three pounds were awarded by the Judges to Mr. Raper's horse, exhibited in this class, on account of his great merit.

CLASS 23.—For the best stallion for coach horses, 10*l.*; first, Mr. Topham's Sportsman; second, 5*l.*, Mr. Easingwood's Boroughreeve.

CLASS 24.—For the best stallion for roadsters, 10*l.*; first, Mr. Young's Greysheils; second, 5*l.*, Mr. Stubb's Rattler.

CLASS 25.—For the best stallion for agricultural purposes, 10*l.*; first, Mr. Palliser's Merryman; second, 5*l.*, Mr. Hairsine's Royal Oak.

[The stallion which gained the first premium in each class, shall serve mares in the county the following season, or the premium to be returned.]

CLASS 26.—For the best mare and foal for hunting, 5*l.*; first, Mr. Raper; second, 2*l.*, Mr. Jaques.

CLASS 27.—For the best mare and foal for coaching, 5*l.*; first, Mr. Gaunt; second, 2*l.*, Mr. Jaques.

CLASS 28.—For the best roadster mare and foal, 5*l.*; first, Mr. Hincks; second, 2*l.*, Mr. Richmond.

CLASS 29.—For the best mare and foal for draught, 5*l.*—no competition.

CLASS 30.—For the best three-year old hunting colt, 5*l.*; first, Rev. J. Higginson; second, 2*l.*, Mr. Wright.

CLASS 31.—For the best two-year old hunting colt, 5*l*.; first, Rev. J. Higginson; second, 2*l*., Mr. Robinson.

CLASS 32.—For the best three-year old coaching colt, 5*l*.; first, Mr. Wright; second, 2*l*. ditto.

CLASS 33.—For the best two-year old coaching colt, 5*l*.; first, Mr. Ingham; second, 2*l*., Mr. Manfield.

CLASS 34.—For the best three-year old hackney colt, 5*l*.; first, Mr. Cattle; only one shewn.

CLASS 35.—For the best two-year old hackney colt, 5*l*.; first, Mr. Robinson; second, 2*l*. ditto.

SWEEPSTAKES.

CATTLE.

CLASS 36.—Best yearling bull, 1*l*.—Mr. R. M. Jaques's roan bull, Clementi (calved 29th Sept., 1838).

CLASS 37.—Best bull calf, 1*l*.—Rev. J. Higginson's roan calf (calved 4th May, 1840).

CLASS 38.—Best two-year old heifer, 1*l*.—Rev. John Higginson's Amazon (winner of class 7).

CLASS 39.—Best yearling heifer, 1*l*.—Rev. John Higginson's Alexandrina (winner of class 8).

CLASS 40.—Best heifer calf, 1*l*.—Rev. John Higginson's Lily, (second in class 9).

SHEEP.

CLASS 41.—Best pen of five shearling wethers, 1*l*.—Mr. William Allen, Malton.

CLASS 42.—Best pen of five shearling gimmers, 1*l*.—Mr. William Allen, Malton.

EXTRA STOCK.

CATTLE.

John Beetham, West Harlsey, Northallerton. One Bull, two cows, and two yearling heifers.—2*l*. awarded.

Henry Carmichael, Sewerby, Thirsk. Two four-year old West Highland bullocks.—2*l*. awarded.

R. M. Jaques, St. Trinians, Richmond. Two cows and two heifers.—2*l*. awarded.

Thomas John Masterman, Little Danby, Northallerton. A half-bred Highland bullock.—2*l*. awarded.

John Charles Maynard, Harlsey Hall. From 20 to 30 cows and Heifers of different ages.—4*l*. awarded.

Lord Feversham, for an aged bull, 1*l*.

SHEEP.

John Beetham, West Harlsey, Northallerton. Two rams.—1*l*. awarded.

PIGS.

Rev. John Higginson, Thormanby, Thirsk. One sow, small breed; and one boar, small breed.—1*l*. awarded.

Chas. Howard, York, two female pigs.—1*l*. awarded.

Samuel Wiley, eleven young pigs.—1*l*. awarded.

HORSES.

Rev. John Higginson, Thormanby, Thirsk. One grey yearling coaching colt.—3*l*. awarded.

SHEPHERD.

To the shepherd, being an annual servant, who shall have lost the smallest proportionate number of ewes from those that produced lambs in 1840, the number of the flock not being less than fifty. The premium was awarded to Joseph Martin, who had only lost one out of 350.

IMPLEMENTS.

For the invention and improvement of such agricultural implements as may appear to the committee to deserve reward, were awarded the following sums:—5*l*. to Mr. Matthew Raper, for an improved corn and turnip drill; and 2*l*. to Mr. Coates, for a double harrow.

The following were also competitors.—Thomas Abbey, Dunnington, York. A portable thrashing machine with an improved straw-cutter to work with the same. An improved hand straw-cutter.

Thomas Bramley, jun., Thornton House, Northallerton. A scuffer and double mould board plough.

William Busby, Newton-le-Willows, Bedale. Some improved harrows.

John Dickinson, Hovingham, Whitwell. A winnowing machine.

Timothy Hopton, Appleton Wiske, Great Smeaton. A scuffer for Wheat, &c.

William Lister, Dalton, Richmond. A one-horse cart on an improved principle.

E. Robinson, Ripon. A new straw shaker.

Joseph Scurrah, of Crakehall. Improved iron scuffers. Iron drag harrow on an improved principle.

John Styant, of Whixley. Atkinson's patent improved thrashing machine.

The Duke of Leeds. A model of a churning apparatus, in brass, mounted on mahogany, in which the power of the lever was usefully applied to lessen the labour. Not exhibited for competition.

John Malthouse, of Ripon. Eleven row management drill. A six row management drill, for four or three rows of turnips or two ridges. Turnip drill for rough manure—three broadcast or two in ridges. A single row turnip drill. A mill for breaking oilcake. A winnowing or blasting machine.

John Chapman, of Thirsk. Single row management turnip drill. A thirteen row drill. An eleven row drill, with improved rappers, for assisting the delivery of chemical manure, linseed, &c.

ROOTS, GRAINS, AND SEEDS.

For new or improved varieties of agricultural roots, graias, and other seeds, the following prizes were awarded:—John Henderson, Castle Howard, Whitwell, a specimen of Italian rye-grass seed, 3*l*.; Robert Hotham, Kilnwick Percy, Pocklington, a specimen of Holstein barley seed, 3*l*.

For the best specimen of wheat in ear, to be accompanied with a thrashed sample of the general produce: 5*l*. to Mr. Christopher Barrowby, Baldersby, Ripon; and 3*l*. to Mr. Robert Hotham, Kilnwick Percy, Pocklington; 3*l*. was also awarded to the same gentleman for a sample of oats.

The sample of rye-grass was grown upon a cold clay soil near the centre of the county of York. The seed was originally obtained from a gentleman in Nottinghamshire, who assured the grower of this that he had proof of its being perennial (not biennial, as by some writers stated). No rye-grass that the grower has ever seen can bear any comparison with it for its luxuriance, its nutritive properties, and its early growth in the spring. In one field the grower had ewes and lambs grazing with a full bite in the last week in March; at least a month before any other artificial grasses were fit to depasture; and the grass in the field where the sample was grown would in the last week in April average in length about eleven inches, and the first week in July would average about from 3½ to 4 feet. The grower has invariably sown it, without any mixture of other seeds at the rate of 2½ bushels to the acre. The grower has this year depastured with sheep two small fields of this grass; and has never at any time had fewer than at the rate of four, and most of the season five ewes with double lambs upon the acre, and the fields have been all summer, and now are, excellent pastures.

DRAINAGE.

To the tenant in the North Riding of the county of York, who shall have drained in the most efficacious, judicious, and economical manner, the largest quantity of land in proportion to his occupation, 10*l*., awarded to Mr. John Foxton.

COMPETITORS.—Robert Abbey, Salton, Kirbymoorside; John Forster, Newton-le-Willows, Bedale; John Foxton, Haram, Helmsley.

THE GRAND DINNER.

At three o'clock the members and friends of the society sat down to dinner in the grand pavilion erected in the court-yard between the court-house and the prison. This building was pretty nearly a square, and was very neatly fitted up. The roof was of transparent oil-cloth, and completely water-

proof, which would have been very beneficial in case of rain, as the company were perfectly secured from the weather; fortunately, however, such a precaution was unnecessary. The president's and judges' tables were placed on a *dais*, fronting the court-house, and underneath was a table assigned to the reporters of the public press, of which there were about ten from the various Yorkshire newspapers. The tables for the public were nineteen in number, and ran in a direct line from south to north; each range of tables being lettered to avoid inconvenience in the company taking their seats. A gallery for the accommodation of the ladies was erected on the left, rather behind the president's table. The pavilion afforded accommodation for 1,400 persons, and the tables when set out presented a most pleasing sight. The dimensions of the building are 118 feet by 53.

The chair was taken by the Earl Spencer; who was supported on the right by Sir E. Vavasour, Bart., Hon. W. Duncombe, M.P., Hon. A. Lascelles, Baron Langen, H. Preston, Esq., Sir S. Crompton, Bart., M.P., W. R. C. Stansfield, Esq., M.P., Archdeacon Headlam, W. B. Wrightson, Esq., M.P., Rev. W. Dent, General Sir John Beresford, Bart., G. W. Wentworth, Esq., J. W. Childers, Esq., M.P.;—on the left by the Duke of Leeds, Count de Gourcey, Hon. Charles Lascelles, Hon. and Rev. T. Monson, M. Wyvill, Esq., Sir R. B. Graham, Bart., P. D. Cooke, Esq., Sir E. Dodsworth, Bart., H. Vansittart, Esq., H. S. Thompson, Esq., Sir R. L. Dundas, Bart., M.P., George Legard, Esq., W. C. Maxwell, Esq., R. Denison, Esq., &c.;—Sir J. V. B. Johnstone, Bart., acted as vice-president.

The following gentlemen were nominated as stewards, each gentleman being indicated by a white willow wand and a white rosette:—W. Armitage, Esq., J. S. Crompton, Esq., T. Lacey, Esq., R. M. Jacques, Esq., J. G. Loy, Esq., W. F. Paley, Esq., Thomas Morley, Esq., Rev. J. Higginson, J. Favell, Esq., Col. Hildyard, C. Topham, Esq., T. Bradley, Esq., J. Rob. Esq., J. Roccliffe, Esq., F. Morley, Esq., T. S. Walker, Esq., Leonard Scvers, Esq., Thos. Charge, Esq., F. Cholmeley, Esq., J. C. Maynard, Esq., John Booth, Esq., E. Squire, Esq., E. Clarke, Esq., Rev. W. Lockwood, H. Glaister, Esq., T. Masterman, Esq., J. Douthwaite, Esq., J. W. Smith, Esq., — Haynes, Esq., T. Dighton, Esq., J. S. Walton, Esq., R. Booth, Esq., T. Hut-ton, Esq., J. Carter, Esq., Rev. J. T. Monson, Rev. J. Wiley, J. Harland, Esq., J. Hutton, Esq., W. Mauleverer, Esq., W. Rutson, Esq., J. T. Wray, Esq., Rev. P. Ewart, T. Fowle, Esq., W. Fowle, Esq., W. J. Anderson, Esq., T. C. Hincks, Esq., R. Hildyard, Esq., Rev. T. Morley, R. Maynard, Esq., J. Manghan, Esq., F. Morley, Esq., Hon. T. O. Powlett, J. Rider, Esq., T. Robson, Esq., L. Topham, Esq., E. C. Topham, Esq., J. Topham, Esq., and some other gentlemen whose names we could not ascertain.

The dinner was served up by Mr. Shepherd, of the Red Lion Inn, and appeared to give the greatest satisfaction to the numerous guests who amounted to upwards of 1,200.

After the cloth had been removed, and thanks after meat returned, &c.

The CHAIRMAN said—Gentlemen, the first toast which I have the honour to propose is one which, I know, does not require any prefatory observations from me (*Applause*). I am perfectly satisfied that you will cordially join me in drinking "The health of the Queen" (*Three times Three*).

The CHAIRMAN said—Gentlemen, the next toast which I have the honour to propose to you, is one

which, since last year, has been added to the usual toasts proposed on public occasions (*Applause*). I hope and trust that we shall have to drink this toast for many years to come; I hope and trust that his conduct will continue to be such as his past conduct has been, and that we may be able to drink his health with the same degree of cordiality as on the present occasion (*Applause*). I give you "The health of Prince Albert" (*Three times Three*).

The CHAIRMAN said—Gentlemen, I did not feel it necessary to use any persuasion to induce you to drink the healths which I have already offered to your notice. I feel confident that the one which I am about to propose will receive the same cordial acquiescence which you have shown in the other toasts (*Applause*). The Queen Dowager, since she has been in this country, has evinced such beneficence, such kindness—has displayed such condescension to all who approached her, that she has attained a strong hold of the affections of the people of this country (*Applause*). I am sure, therefore, you will drink her health. With respect to the other members of the royal family, they have ever been prominent in promoting every charitable institution; and in doing all they can to alleviate distress, and benefit the people of this country. I am sure, therefore, you will cordially drink "The health of the Queen Dowager and the rest of the Royal Family" (*Three times Three*).

The CHAIRMAN said—Gentlemen, before I propose the next toast to your notice, I think it my duty in the first place, to state to you some matters which are strictly matters of business. You are aware that on the present occasion the three years, my term of service as your president, expires; and to-morrow I shall cease to hold that office. The committee have decided to recommend to the society, as our future chairman, Lord Wharcliffe. (*Cheers*.) We feel quite confident, from his personal recommendations, from everything we know of him, his rank and station, you will confirm his appointment. (*Applause*.) Another point which I would allude to is, the place of our meeting next year. It has been decided that it shall be at Hull. This is a most convenient place for the conveyance of animals, and also for those gentlemen who wish to be present—there being ready railway and water communication. Therefore I hope that Hull will afford us as good a meeting as our present and former meetings. (*Cheers*.) Having said this much on matters of business, I cannot propose the toast I have to offer to your notice without congratulating you on the success which we have had to the present time. (*Loud applause*.) I sincerely hope that Lord Wharcliffe, when he retires from the same office, at the expiration of his three years, will have had the same success which I have experienced. (*Hear, hear, and cheers*.) We have gone on from year to year improving. At the first meeting in York it might be said the novelty led to a great number of persons coming among us; at our second meeting, which was in the populous town of Leeds, it was not surprising that we should have a large meeting. But this year we have had a great meeting. Although we are purely agriculturists, and had to depend upon our brother farmers, we have had the full number to look at our show—we have have had a superior exhibition to any former occasion, and now I have the honour of addressing you at as large a meeting as in any former year, and in addressing you, I know I address men who are all interested in agriculture (*Applause*). Although, in counting noses we have not increased our numbers, in counting farmers we have increased

(*Applause*). Practically, we have had a larger and more successful meeting than we ever had before (*Applause*). That being the case, I cannot help feeling confident in the prosperity of our society (*Applause*). It is now not a new experiment; we have tried and succeeded, and I am confident we shall derive the benefits which we anticipated (*Applause*). I trust that we have set an example in this great county which will tend to the improvement of agriculture. We meet in union and good fellowship to promote the object we have at heart, and I am certain that our endeavours will confer the greatest benefits to this county, ay, not only to this county, but also to the kingdom at large. Gentlemen, I propose to you, "Success to the Yorkshire Agricultural Society." (*Three times Three.*)

The Hon. W. DUNCOMBE, M.P., on presenting himself, was received with loud and enthusiastic cheering. He said, My Lord Spencer and Gentlemen, the next toast having been allotted to me, I have now the honour of rising to bespeak your attention, and although I cannot but regret that it has not fallen into abler hands, I am, nevertheless, free to acknowledge that it is to me matter of sincere congratulation, that I should have the honour of proposing to you the toast which has been assigned to me—The health of the noble President (*Loud cheers*). And in proposing that toast to you it must be obvious to every one, that I am proposing the health of a nobleman, who for a long series of years, has been the zealous friend and staunch supporter of agriculture and of agricultural improvements (*Loud cheers*). The society which is celebrating its anniversary at Northallerton this day is indebted in the highest degree, to the noble earl for the favours he has bestowed upon it by accepting the office of president, and the society has thus had the advantage of the noble earl's experience and knowledge of agricultural subjects, which I have no hesitation in saying, has considerably enhanced their value and importance (*Cheers*). If I might be allowed to express my own opinions, I should say that the pursuit of agriculture, the cultivation of the land, and the improvement of the fertility of the soil, is one of the most delightful and most instructive, and the most honourable pursuit in which a man can be engaged (*Loud applause*), and not only leads him to contemplate the wonders of creation and the works of nature, and of nature's God, but it also enables him, by the aid of successful industry, and by the application of science, to effect improvements which, under the blessing of divine Providence, cannot fail to be advantageous both to the age in which he lives and the generations yet to come. (*Loud applause.*) And although I should not for one moment undervalue or disparage the importance of any other great interest of the country, permit me to say that it appears to me that those who inhabit our crowded cities, and carry on their avocations in our towns—although undoubtedly the degree of perfection they have attained and the degree of science they have accomplished, are excellent and even wonderful—yet they are not the only persons who ought to be ranked amongst the benefactors of their country. (*Loud cheers.*) Those amongst us who are living in the more sequestered and less populous places, the agricultural districts—who are following the pursuits of an agricultural life—devoting their time and attention to the study and improvement of agriculture and the productiveness of our land—they, I say, are eminently entitled to the gratitude of their country, (*loud applause*), and should be

considered as being amongst the list of those who have conferred upon it the most essential and important benefits. (*Cheers.*) At the great annual meeting of the English Agricultural Society, held about three weeks ago at Cambridge, we were honoured with the presence of several of the learned professors of the University; and amongst others, with that of Dr. Buckland, the celebrated professor of the University of Oxford, and he stated, that although much had been done for agriculture of late years, much yet remained to be done. A knowledge of the different properties of the soil, and a judicious administration of the various strata, might, undoubtedly, tend to the improvement of the corn grown in this country, and, in some degree, provide better for our rapidly improving population. (*Cheers.*) These are subjects worthy of the consideration of the Yorkshire Agricultural Society, of which the noble lord is president; and from which office, as he has told you, he is now about to retire. I now call on you to drink his health in such a manner as will prove to him your gratitude for the time and attention he has devoted to your interest; and most heartily join with him in the hope that as he has witnessed improvements during the three years he has been your president, he may also find that the same degree of zeal and sincerity in the cause of agriculture may continue to characterise all our proceedings. (*Cheers.*) I have to propose "The health of the Right Hon. Earl Spencer." (*Tremendous cheers.*)

Earl SPENCER spoke as follows:—Gentlemen, I return you my most sincere thanks for the honour you have done me, and for the manner in which you have done it. As I have already told you, I am about to retire from the office, which I have now held for three years; this is, therefore, the last occasion on which I shall have the honour of addressing you from this place; but it is not, I trust, the last time I shall have the honour of addressing you from another place. (*Cheers.*) Although I shall not have the honour of being able to continue my services in the situation I at present hold, I hope I shall, in some other situation, be able to continue to offer you the best services in my power towards promoting your prosperity, and of contributing towards the flourishing state of your society. (*Cheers.*) I have always considered (and I always shall do so,) that it was a very high honour to have been selected as the first president of this society. (*Cheers.*) If you were looking for a president connected with your county—if you were looking for a person possessed of great property in your county, or even for an individual residing in your county—I am not the person to whom you would apply. I have no claim whatever to take the office which you did me the honour to confer on me; but if, as I believe was the case, you wished to find a man devoted to agriculture, and to agricultural pursuits—enthusiastic I may say in them—if you wanted to find a president who was desirous, in the greatest degree, to promote the improvement of agriculture throughout the whole country, I am ready to say, that you could not have chosen one possessing that desire more than I do. (*Cheers.*) Those around me may have the cause at heart as much I have, but I do not think that any have it more; and, in saying so, I am not perhaps saying too much. (*Cheers.*) You are all aware that in the course of my life—now not a very short one—I have applied myself to many and various pursuits, (*cheers and laughter*), but I have at last come to that which I believe to be my natural one—I mean the improvement of agriculture—the promoting of agriculture by

my own endeavours, and by assisting the endeavours of others (*Cheers*). Mr. Duncombe told you it was a pursuit worthy of being followed; I will tell those who are entering upon life that they will find no pursuit which gives more satisfaction—I will say they will find no pursuit which will give so just an occupation of their time with less annoyance and less disturbance to their tempers (*Cheers*). No other in which they will feel such full satisfaction that they are doing good in pursuing their own pleasures at the same time that they are improving the cause of agriculture (*Cheers*). We have emulation among us, and I hope we always shall; for if we have not emulation we shall never succeed; but, if we have emulation I hope it is far removed from the spirit of rivalry (*Applause*). Because, although each of us may wish to have as good cattle as himself (*Applause*). Agriculture is a pursuit to which one and all of us should wish success. It is one of those pursuits which is most delightful to follow; it is a pursuit which may be carried on without time ever hanging heavily; an occupation interesting in the highest degree, and while the agriculturist is promoting his own interest, he also promotes the interest of every one of his neighbours (*Loud applause*). I say, I am most enthusiastic in promoting the cause of agriculture, and therefore, as I said before, if your wish was to select a man as your president, who was likely to devote the whole of his energies to this subject, you could not have selected one more inclined to do everything to the utmost of his power to effect that object than myself (*Loud applause*). But, whatever was your object, or the reason for your choice, I certainly feel that you have conferred on me one of the highest honours, and I shall look back to the time when I had the honour of being your president for three years, with the greatest satisfaction (*loud applause*); and should it please the Almighty to prolong my life, I shall doubtless see you promoting the advancement of agriculture, benefitting the whole country, and distinguished by taking the lead in combining science with agriculture, throughout the whole kingdom (*Applause*). I now, gentlemen, return you my most sincere thanks for the kindness you have conferred upon me, and for the support you have given me since I have been your president, and I beg to drink all your healths. (The noble Earl upon resuming his seat, was loudly cheered.)

The CHAIRMAN then said—Gentlemen, on the two former occasions we have met we have been indebted to the commander-in-chief for the accommodation which he gave us, both for our show and the places in which we dined. On this occasion, meeting, as I have already said we have done, in a purely agricultural district, we had to depend upon others for that assistance. The magistrates of this riding have kindly given us permission to dine in the present building. I need not tell you, because you are witnesses of it, how convenient a building it proves to us on the present occasion (*Applause*). I think it quite as convenient, if not more convenient, than any meeting we have had. You are the better judges; yet I have had some practice, and am therefore a tolerable judge, and I believe I make myself heard throughout the whole room, which is an object not very easy to obtain. We are obliged, therefore, to the magistrates of the North Riding of Yorkshire, for having given us this accommodation; and I have no doubt you will cor-

dially join with me in drinking the healths of the magistrates of the North Riding, and thanks to them for the accommodation they have afforded to me (*Applause*).

Sir J. V. B. JOHNSTONE was then called upon. He said—My lords and gentlemen, although there are several gentlemen in this room, and at the elevated table, to whom, in my opinion, the answer to this toast could have been more appropriately allotted than to myself, still, in obedience to your lordship's call, I beg to return you the best thanks of the magistrates for the honour you have done them, 'in drinking their good health, and to assure your lordship and the gentlemen present that they felt it to be their duty and, at the same time, their greatest gratification, to be able to afford to this society that accommodation which these premiums afforded, as far as it could be done, without inconvenience to the discipline of the unfortunate individuals kept within these walls, and without injury to the building; for, my lord, they felt that by so doing, they were promoting the best interests of agriculture (*Applause*). It was natural that they, as landlords, and connected with the soil, should have their feelings and interests bound up with the success of agriculture; but it was not only as landlords that they were anxious to give to this institution the benefit of the accommodation, but because they feel that the best interests of this country are involved in the successful carrying out of the great objects which this institution was established to promote (*Hear, hear, and applause*). I say the best interests of this country, because in the present state of our population, depend upon it there is no object of such importance amongst all the great national interests, as that which has for its object the increase in the production of the food of man (*Applause*). I am not one of those who undervalue the labour of those who ply the loom, or engage in the other great branches of British enterprise, but he who is able (without increased cost) to make two bushels of corn grow where one grew before, (and though this is an old saying it is not on that account the less true) is as great a benefactor of his country as those who carry into practical effect the grand discoveries of a Watt or an Arkwright. You have been often told that one of the most valuable ends of institutions of this kind is that they connect together the practical farmer and the theorist. I am one of those who think nothing so valuable as the experience of practical men drawn from the concurrent testimony of farmers, and thus by the diffusion of knowledge by each man to his neighbour, a great advantage will accrue to the cause of agriculture (*Applause*). But I also feel persuaded the farmers of Yorkshire will only think they are doing their duty if they annually devote a small sum of money with the view of obtaining the services of persons eminent in those particular sciences more immediately connected with agriculture—those eminent men holding out to us as they do the right-hand of fellowship and good will, be they chemists, geologists, botanists, or men connected with mechanics. By devoting a small sum we shall enlist their services in our cause, (for you will agree, that experience though very good, is often rather dear,) to scrutinize nature in all her paths, to trace effects up to their causes, to enlarge the sphere of agricultural knowledge, and to be a signal to guide us while they will be a beacon to warn us (*Cheers*). If a gentleman be not very fond of his soil, let him take it to a chemist, or to a practical geologist, who would point out to him that particular ingredient or kind of manure which would be beneficial to his land. I have alluded to these subjects, because it was

the intention of the Committee of the Agricultural Society to obtain, under the auspices of Professor Phillips, a survey, on a limited scale, to see what management was suitable to different districts, how it was modified by the substratum under each soil, and the geological condition of it. This being our first entrance on this path, we were anxious to obtain the services of one eminent in his profession, in order that our investigation might accrue to the benefit of agriculture (*Applause*). It is with extreme regret I have to announce, in consequence of Professor Phillips's professional engagements, (which were such, that if they had been interfered with, it would have caused the greatest inconvenience to him), we have been unable to carry out that intention. But, gentlemen, no money has been expended upon it. We have it ready, and if Professor Phillips's other avocations will allow him to devote his time to this difficult subject, it is the intention of the committee to have this investigation conducted in a way which will meet with the approbation of all who wish well to agriculture (*Applause*). The Hon. Baronet again returned thanks, and sat down amidst loud applause.

WM. CONSTABLE MAXWELL, Esq., then rose and said, my Lord Spencer and gentlemen, I regret extremely that a more able person than myself should not have been selected to propose the toast with which I am entrusted: it is the health of the successful candidates for cattle. (*Cheers*.) I am sure we are all indebted to those gentlemen for the manner in which they have improved the breed of cattle in this country; and, I can say of the meeting to-day, that there is not a part of England, where more beautiful stock could have been shown. (*Applause*.) Gentlemen, I wish I could do justice to the toast, or to the individuals to whom it refers, or to the number and breed of the cattle they have exhibited; but I am sure, though we may envy those gentlemen their beautiful stock, yet still we shall not grudge them those thanks to which they are most justly entitled for the beautiful cattle they have brought this day to our exhibition, (*Applause*.) May they and their families long enjoy that which we all hope to enjoy through life—the roast beef of old England. (*The toast was drunk amidst loud applause*.)

J. BOOTH, Esq., said, my Lord Spencer and gentlemen, I rise in the name of the successful candidates to return you our best thanks for the compliment you have just paid us in drinking our health. (*Applause*.) And I can assure you, that we have been highly gratified with what we have seen to-day, and I hope that no exertion will be wanting on the part of my brother farmers, of the North Riding, to promote the interests of the Yorkshire Agricultural Society. (*Cheers*.)

JOHN WELBANK CHILDERS, Esq., M.P., said: My Lord Spencer and gentlemen, I regret that the toast which has been allotted to me has not been allotted to some one more conversant with the breed of sheep than I am, being myself a very young farmer. As yet I cannot boast of any sheep I have produced, nor have I any confidence in my own powers in that branch of agriculture. And this toast, I believe, has been allotted to me by the committee from an idea that a short paper which I recently inserted in a publication of the Royal Agricultural Society of England having excited some attention among the breeders of sheep, they might like to have from me *vice versa* some few particulars about it (*Cheers*). The point which my very few observations will embrace is the extraordinary increase in the growth and condition of sheep by being fed under cover, in an open yard, with a shed in it. This idea had no doubt

occurred to many others besides myself, but I am not aware that any one has so fully examined into the effects attending that enquiry as I happened to do in the course of last winter and the winter before. Gentlemen, the principle is one that we have acknowledged in every practical way, by everything that eats, namely, that if it has plenty to eat, is warm, and has nothing to do, it is very likely to increase (*Applause*). I certainly was not aware, until by repeated experiments I tested the truth of it, namely, that the same animals when placed in the shade and kept warm, not only increased rapidly, very much more rapidly in their condition and weight than when out in the open air, but also that they consumed a much smaller quantity of food. This I have tested, both last year and this. I have not the papers by me to refer to, but as far as my recollection goes, it is this, that the quantity of food consumed was less by at least one-third, and that the increase of weight was fully one third, taking it in round numbers. At the beginning of the season I built a shed which will contain about eighty hogs (a shed which will serve for cattle as well), and I merely put down a few rough planks for the cattle, as I have found that it is a great advantage to have boards to lie upon, and if they had straw, and it was to get wet, they would be liable to get the rot in their feet. I brought those animals up last Christmas, and I found that before two days had elapsed they did not eat so much as when they were out of the fold, by the proportion of five to three. When in the fields they eat fifty basketsful of turnips, but when brought up they eat only thirty a-day, therefore their improvement was in the inverse ratio of their cost. Yet such great progress did they make that you would have thought they had been eating fifty baskets a day when shut up, and only thirty when in the field. I gave them with their turnips a little oilcake, and certainly the size they grew to was so very great, that at thirteen months old I sold them without their wool for 73s. a-piece—(*cheers*)—and I really believe that if the turnips be pulled and brought into the shed they will go twice as far as when consumed in the field. (*Cheers*.) Gentlemen, after these few observations let me tell you that the toast which I have to propose for your acceptance is “the successful candidates for sheep.” (*Hear*.) This is pre-eminently a cattle district; and therefore, perhaps, the show of sheep is not so great as we have seen it. When we get into the country of the wolds we shall see more. At the same time, as far as my judgment goes, the sheep shown were very good. Those belonging to Mr. Allen, of Malton, were very fine, and Mr. Garforth's tup has the merit of having won three prizes this year, first at the Hackness show last month, secondly, on Monday, at Thirsk, and again to-day. (*Cheers*.) Allow me, before I sit down, to say a few words with regard to the other parts of the show. I consider that the show of cattle was the finest as to the short-horns that ever was seen in England. (*Loud cheers*.) I have seen several shows; I have been at both the Cambridge and the Oxford exhibitions, and also at that which I believe was superior to either of them—the show at Otley in the spring. (*Loud cheers*.) With that observation I may say that I think this show is the finest that ever was seen. We are going on progressively, and our shows are likely to go on and be better every year. And let me congratulate you that not only have we been honoured with the presence of the ladies on this occasion—(*loud applause*)—but also for the first time many of them have honoured us with their attendance in the show fields. This is an advantage which we derive from coming

into a beautiful agricultural district, with pleasant green fields. It shows that her Majesty's barracks-yards are not so fit as the pleasant green fields. Many of the ladies, I am sure, appreciate the show of animals as much as the other sex. (*Loud laughter.*)

"The successful candidates for sheep."—(Three times three.)

WILLIAM GARFORTH, Esq., said—My lord and gentlemen, I am proud of the pleasure of being present on this occasion, surrounded as I am by so many friends, breeders of short-horns, of sheep, and of horses, and other animals. I feel much flattered by the award of the prize to me for my shearling sheep, especially when I consider that I was a competitor with so many experienced farmers and sheep breeders. It was far from my expectation to gain a prize even on the first occasion, but when I heard, on my arrival here this morning, that I obtained a prize at Thirsk, and now know that a third prize has been awarded me, I am almost surprised at my own success. (*Cheers.*) In my own name, and in the name of my brother competitors, I beg to return you our thanks for the compliment paid to us, and for my own part, to assure you that so far as my humble support to agriculture can be given, it shall always be readily afforded. (*Applause.*)

H. S. THOMPSON, Esq., said—I rise with pleasure to propose the health of the successful competitors for pigs. (*Applause.*) One of the peculiar features of this society is the extreme harmony which pervades all our members. When we assemble at our great meetings we agree to forget our political differences and to lay aside our religious opinions, remembering that we are members of the same family, having one common object in pursuit; this object is dignified by being for the promotion of all ranks and classes of life. (*Applause.*) It is with much pride that I propose the toast which has been allotted to me; because I believe there is a great unanimity of opinion among us, that from the prince to the peasant the grunt of the pig furnishes a rich and savoury recollection. (*Applause.*) It would indeed mark the highest ingratitude in you, if you did not receive the toast with great cordiality; because I believe that there is hardly a person who has not made a meal on some part of the pig. (*Applause.*) It has been universally reported, and I believe it is true, that the farmer was attached to the pig from ancient recollections: therefore the pig ought to be held in respect and esteem. (*Applause.*) Noah, the patriarch, showed his respect and esteem for the pig by calling one of his sons Ham: and to come nearer to our own time, the sitch of bacon has long been held out as a sufficient reward for connubial happiness. (*Applause.*) From the observations which I have made, I fear that instead of proposing the health of the successful candidates, you will think that I am about to propose the health of the pigs themselves. (*Applause.*) We are greatly obliged to the judges of pigs, and also to the candidates who have by the great merit of their stock given the judges considerable difficulty this day. These people are entitled to our praise; for they have not only contributed to our pleasure this day, but also benefited us by improving the quality of the hams and rashers of bacon which adorn our tables. (*Applause.*) I will not trespass on your time longer, lest you should consider that I am a bore. (*Laughter.*) I give you—"The successful competitors in pigs."—(Three times three.)

The Rev. J. HIGGINSON said—Being a successful candidate in the swinish tribe, I return you my most sincere thanks. I have shown in that class very largely, and have been equally successful this year

and last. I have also exhibited in horses and cattle, in all of which I have been successful; and, if spared till our next exhibition, I will show in all these, and also in sheep. (*Applause.*) I will do the best I can; and after the great kindness I have received, I shall consider no distance too great to send my stock. (*Applause.*) This is the second year that I have attended these exhibitions, as an exhibitor; his lordship, our noble chairman, knows from whose stud I purchased my stock—Mr. Wiley was the gentleman from whom I procured it; and I am entirely indebted to him for the stock I possess; and as long as I have a shilling to give him, I will go to him again. (*Applause.*)

ROBERT DENISON, Esq., next rose and proposed the "Successful candidates for horses." He said, his friend Mr. Thompson had, in speaking of pigs, expended almost every term of eulogy and praise. Horses, however, in his opinion, ought to come before pigs, although, he was willing to allow that that animal possessed qualifications calculated to recommend it to the favour of society at large. (*Laughter.*) He found that Mr. Thompson had just left him one single qualification which he certainly might claim for the horses over the pigs (*laughter*), and that was action. He believed that the latter were not much famed for the beauty or elegance of their action. (*Laughter.*) Being a resident in the East Riding, he had always considered that division of the county as celebrated for its horses, but he confessed it was with some degree of fear and anxiety, for the credit of the East Riding, that he had witnessed the splendid show of cattle and horses which had been exhibited that day; and he believed, he must acknowledge, that in this respect the cattle shown at the East Riding exhibition were inferior to those shown that day. But although they were not so much a *beast district*—(*laughter*)—he thought that they (the East Riding) could make up for their deficiency in cattle, by their show of sheep. (*Loud cheers.*) He would not sit down without saying, and he was sure it was the feeling of all present, that whoever might be the committee appointed to manage the business of the exhibition at Hull next year, it was impossible that they could succeed better than the committee had done at Northallerton. (*Cheers.*) For his own part, he should be contented if they did anything near as well, and he would only say, in conclusion, that when they met at Hull, he trusted they should meet as large a concourse as they did here. He then gave "The successful candidates for horses."

The toast was briefly acknowledged by one of the gentlemen present.

WM. RUTSON, Esq., next rose and said, my Lord Spencer and gentlemen, the toast which has been committed to my care is one of the latest of the series; and, gentlemen, you are doubtless aware that the premiums connected with the class of animals to which this toast refers has not been given by the society, but by the generosity of one of its firmest friends. (*Cheers.*) Gentlemen, the larger animals which have obtained prizes have been duly celebrated; I will now endeavour to obtain your good-will while I advocate for a few minutes the claims of the animals mentioned in my toast. They possess especial claims upon your sympathy, a great deal has been said about ham, and I can assure you they make excellent companions to that dish, (*a laugh.*) I do not think that ham ever appears to greater advantage than when in the company of turkey. (*Laughter.*) I think those gentlemen who originated this prize, must have had something further in view than what is at first sight apparent—they

must have thought as I do, that farming is not a trade in which men grow rich at once. (*Applause.*) Gentlemen, I consider that every part of the farm should be turned to good account. I think you will concur with me that no part of the produce of a farm ought to be wasted; and, therefore, I would respectfully urge upon all the advantage of keeping poultry. In the consideration of this question it appears to me that you will have some difficulty in separating those animals from the person who has the care of them. The sheep are confided to the shepherd; the ox to the herdsman; and that more noble animal, the horse, to the groom; but, gentlemen, you will see for the most part, the animals I allude to, are confided to women. (*Applause.*) And you will all, I am sure, agree with me that whenever you trust a woman, she is invariably faithful to you. (*Loud cheering.*) Therefore, gentlemen, you will not, I am sure, while drinking this toast, separate this idea from your mind, but will consider that you are drinking the health of a daughter, a sister, or a mother of each of the company. (*Applause.*) He then gave "the successful candidates for poultry."

The Rev. JONV MONSON acknowledged the toast. He said: My lord and gentlemen, in the name of the successful candidates for poultry, I beg to offer you their best thanks; and to express how much they feel flattered by the attention you have shown to them this day (*Applause*). And having said this much upon this subject, it now becomes my duty to propose the next toast. "Prosperity to the Agricultural Labourers." I consider this body as one of the most useful and efficient of society (*applause*); and perhaps I shall not be thought presumptuous when I take the liberty of stating that I have stronger claims to speak in their favour than most other gentlemen. I have visited them while laid under privations and afflictions of the worst description; I have observed their patient endurance of those privations; I have seen their great exertions to provide for their wives and families (*applause*); and, my lord, I have also visited their humble joys during the hour of recreation; and I have generally had the satisfaction of seeing them behave with modesty and respect towards their superiors (*Applause*). I contend that this feeling of kindness ought to subsist between the landlord, tenant, and labourer; for they are all equally interested in each other's welfare, and ought to be united in one bond of sympathy and regard (*Applause*). My lord, may it please Almighty God to grant that this society may long continue its operations (*applause*); and I feel assured that you will all join with me in drinking, from the very bottom of your hearts, "Success to the honest Agricultural Labourer" (*Loud Cheers*).

JOSHUA CROMPTON, Esq., rose to propose the next toast, but his position being at one side of the room, he could not be heard by those in the opposite one; there were therefore loud cries of "get upon the president's table," which Mr. Crompton at length very agreeably complied with. He spoke nearly as follows:—In my humble situation as one of the committee, I have the honour of proposing a toast to your notice this day; it is the health of the illustrious vice-presidents of this society (*cheers*). Those high and distinguished noblemen who compose the vice-presidents of this society are the Duke of Leeds (the noble duke who was seated in front of the elevated table, was saluted with the most vehement cheering), Earl Fitzwilliam, the Earl de Grey, the Earl of Zetland, and Lord Faversham. (Each of the names of the above noblemen was received with loud cheers.) Now, gentlemen, if I was merely addressing persons who compose the popula-

tion of the North Riding of the county of York, some of their names would not be so intimately known to you, but as I know that I am now addressing persons who have come from all parts of the kingdom, but more especially from the three Ridings which compose this magnificent county, I think it is unnecessary that I should say much as respects their many virtues. Gentlemen, the five names which I have mentioned to you have long been endeared to most of you whom I have now the honour of addressing, by the many virtues of their owners; they are not only known and appreciated by this county, but throughout the whole kingdom (*Cheers*). Were I merely to call your attention to one of the five noblemen whose names I have presented to your notice, I am confident that you would drink his health with the greatest degree of enthusiasm; but now that I have called upon you to drink the health of the whole five, surely, gentlemen, I may expect that you will drink the toast with the greatest acclamation, which you think is due to these illustrious individuals (*Loud cheers*). I do not ask you to give them three times three—that you would give to any of them; but I ask you to give them that which is due, and which by their conduct they have deserved, and if they will allow me to give the time, we will make a shout that will be heard from one end of Northallerton to the other (*Loud laughter and applause*). I now give you "The Vice-Presidents, the Duke of Leeds, Earl Fitzwilliam, Earl de Grey, the Earl of Zetland, and Lord Faversham" (*Cheers*).

The Duke of LEEDS rose and spoke nearly as follows:—My Lord Spencer and gentlemen, as one of those individuals who have been honoured with the office of vice-president of this society, and whose health has just been drunk, I beg, in their names and in my own, to return you our best thanks for the honour you have done us (*Applause*). This I consider to have been a great day for Yorkshire, more than 1,400 gentlemen, I believe all engaged in the same pursuits and all having the same object in view—the advancement of agriculture—meeting together (*Applause*). After a day spent in examining and deciding to whom the premiums should be awarded—a task of no little difficulty, as I consider it to have been the finest stock ever seen—you are now met to celebrate your annual meeting by an interchange of the most friendly and social feelings (*Applause*). I congratulate the meeting and the county at large, upon the support which the farming interest has received (*Cheers*). Long may you continue to see the fine specimens of true stock that have been this day produced (*Cheers*). The owners, gentlemen, may justly feel honoured by the praises that have been bestowed upon them, more especially by the encomiums which have been passed on them by the judges (*Loud applause*). My lord and gentlemen, this is an age of improvement; every day we see, furnishes some improvement in civilized life—and why should agriculture remain stationary? (*Applause*). There can be no true ground for this. And when we see, throughout the length and breadth of the land, associations forming, and assemblies taking place like the present, for the purpose of encouraging all kinds of improvement, and for investigating any new discovery or invention, as regards the cultivation of the land or the improvement of stock, the greatest possible good may be expected to result (*Applause*). Gentlemen, in the name of those associated with me in this toast I beg sincerely to thank you, and I only regret that the duty has not fallen upon one more able, and one who has had more experience in stock than myself (*Applause*). The noble duke concluded by wishing that the noble chairman and those who acted with him in the cause of agriculture might long be spared to them to continue their efforts, and might every success always attend them. (He was loudly cheered on resuming his seat.)

M. WYVIL, Esq., said—I make no apology for offer-

ing the toast which I am about to give, because I feel confident that we should do a great injustice to the individuals who have taken a prominent part in the arrangement of this meeting, if we omitted to drink their healths. To the stewards we are much indebted for the arrangements in the field, and also for the facilities they afforded to the judges. I would also include the judges in my toast, because I am certain we are greatly indebted to them. No doubt the successful competitors are satisfied with the decisions, and I hope that those who have been disappointed will not allow any improper feeling to enter their minds, but will determine another year to be, if possible, more successful. I will give you the stewards and the judges, and I hope you will join in a general cheer to their health and success.—“The Stewards and Judges of the Show.”—*Three times three.*

Mr. TORR, one of the judges, returned thanks. He said:—I rise to respond to the toast which has been drunk, with feelings of pleasure, and beg to express the warmest gratitude of myself and my colleagues, for the compliment which we have received. (*Applause.*) Gentlemen, I regret that the task has not devolved on abler hands; I have yet to learn why one of the judges should be called upon to return thanks for a compliment which is more due to the stewards than to the judges. The stewards rendered us very great assistance by their excellent arrangements for bringing the stock before us. (*Applause.*) I have recently been at an exhibition at Beverley, where I alluded to the breeding of stock in the North Riding; for which it is as distinguished as the West Riding is for manufactures. The breed of cattle in Durham and the North of Yorkshire have not only supplied the whole of England, but the civilized countries of Europe and the the British colonies with an improved description of cattle, and I anticipate that our colonies will one day become famous for their stock, for the breed of which they are indebted to this and the adjoining district. (*Applause.*) I congratulate you on the splendour of your meeting this day—a meeting of the first importance, as I consider this is the first county association in England, second only to the English Institution. (*Applause.*) Having said so much, I would venture to allude to a subject most material to agriculture—the connexion of science with every part of farming. Much has been well said by the Hon. William Duncombe on this subject, and I would add my opinion as a tenant farmer, I have derived great advantage and benefit from the small degree of scientific knowledge which I happen to possess. I have paid some attention to elementary philosophy, which has taught me, when disappointed at the result of experiments, to be gratified at the attempt. The gratification will always exist when we are able to look at the cause as well as effect. I am not one to deprecate practice, but practice is better carried out by coupling of science with it. (*Applause.*) Gentlemen, I beg to return you again our sincere thanks, and drink all your good healths. Next year, we hear that the meeting is to be held at Hull, when I shall attend, not as a judge, but to offer some stock for the opinion of other judges. (*Applause.*)

The CHAIRMAN then said:—Gentlemen, I feel that we owe so much to the exertions of the local committee of this place, for the arrangements they have made for our show this day, that I could not resist reserving to myself the right of proposing this toast. Gentlemen, I am sure the general committee have done their best to promote the success of this society; but it would be impossible for them to go into details, and attend to the necessary minutiae, unless they had the assistance of gentlemen living on the spot, acquainted with every person who ought to be employed, knowing the locality and everything connected with the town. On the present occasion we had the good fortune to find gentlemen resident here who have devoted the whole of their energy, and taken the greatest pains in making the arrangements. (*Applause.*) In making these arrangements in a town like Northallerton, there are greater dangers to encounter than where are larger spaces already provided for exhibitions. In this case

the committee had to choose ground on which to have their exhibitions, and they have selected it with very great judgment and skill. They have had to make arrangements that the ground should be protected, because the fence we had for the ground to-day is an inferior one compared with the fences we had on former occasions; but, partly owing to the arrangements they have made, and partly—I would rather say, principally owing to the conduct of the agricultural inhabitants of this neighbourhood, no confusion arose—an attempt was made to intrude on the show-yard, and everything went on as if they had had a wall twenty feet high surrounding the show-yard. (*Applause.*) Those duties imposed peculiar difficulties on the local committee, but they have overcome them all. (*Applause.*) When I arrived on Monday last, I found everything in the most perfect order; there was no preparation to make, and no exertion was required on my part; I have merely to say, that everything was done which I could wish, and which I was sure the public could wish. (*Applause.*) Supposing the local committee had been negligent in their duty, it would have been impossible that the general committee, in the short time during which they were in the town, to have made arrangements which would have secured the success of the exhibition. In every respect and for every reason, I conceive we owe a debt of gratitude to the exertions of the local committee. I therefore propose the “Health of the Local Committee,” with three times three. (*Cheers.*)

Sir S. CROMPTON said, my lord and gentlemen, although I have been called upon to return thanks for the local committee, I cannot take to myself the merit which belongs to the other gentlemen; it is true there has been a very active, intelligent, and laborious committee of this place, I was nominally a member of that committee, but having other duties to perform it was impossible for me to give that attendance which I ought to have done, if I had not been prevented by causes which were totally unavoidable. It is, however, my lot to return thanks for the local committee. I certainly think, from the character of that committee, that no subject would be left unfinished and incomplete. With regard to the chairman of the committee (Mr. John Monson) he has filled the office much better than I could have done. He took all the laborious duties which belonged to the chairman and he was very ably seconded. (*Applause.*) It is equally unnecessary to expatiate on the merits of Mr. John Monson—it was well known he was ever ready to come forward in promoting any work of a benevolent character; he has devoted himself to the improvement of the condition of the labourer by the allotment system, and when named he came forward most readily as chairman of the committee. (*Applause.*) There is a wide field opened for improvement in this neighbourhood, and I believe the tenantry are most anxious to take advantage of every improvement that is made in agriculture. I beg again to thank you on behalf of the committee for the honour you have done us.

The CHAIRMAN said—I could have wished it had not fallen to me to give the toast which I am now about to propose, because although I am not properly named a member of the general committee I am officially connected with it, and have attended all its meetings. I have always acted with it and therefore am in part responsible for its proceedings. I had hoped that some other gentleman not connected with the committee would have proposed the toast, but no one having done so, though it is in part proposing my own health, I am persuaded you would not have been satisfied to have been allowed to separate without drinking the health of the general committee who have hitherto conducted the business of the society. (*Cheers.*) Gentlemen, in proposing this toast I have very little to add to what I said when I last addressed you, because the topics on which I should have to dilate would be topics very similar to those I made in proposing the health of the local committee. The general committee have, however, more extensive duties, and are in fact the governing body of your society. They have performed their duties well,

and the success which has attended their efforts is a sufficient proof. Gentlemen, this being the case I am quite certain you will agree with me that we should not do our duty by them if we did not drink their health, I therefore beg to propose to you.

"The General Committee."—3 times 3.

The Hon. Sir EDWARD MARNADUKK VAVASOUR, Bart., responded to the toast. He assured the meeting that the general committee were amply repaid for any trouble or labour they had experienced by the success which had attended the establishment of the society. It had no doubt been their anxious object to promote the objects of the society, but they would not have been able to effect it had they not been cordially supported by the honest tenantry (*Cheers*). It was amongst them that the society most particularly wished its branches to extend. Before the next meeting the country would be more connected by railways, and thus the means of transit would be easier, and the attendance at each future meeting consequently larger. Before the establishment of the Yorkshire Agricultural Society their had been district exhibitions of stock at Thirsk, at Beverley, and at Otley, but good as those shows had been it was thought desirable that Yorkshire should take the lead in this as in other matters, and he hoped it would take the lead in every branch of improvement. It was the largest county in England, and ought to be foremost in improvement, and he hoped the formation of this society would give a stimulus to the agriculture of England (*Loud applause*).

The NOBLE PRESIDENT rose and said—Gentlemen, I have stated to you that I regretted very much that it should have fallen to my lot to propose the last toast; on the present occasion, however, I feel, in proposing the toast which I am about to do, no regret whatever. (*Applause*.) On the contrary, I feel the greatest possible pleasure in proposing the toast, which is the health of the President elect, Lord Wharnccliffe. (*Loud applause*.) I feel the highest respect for his lordship, and I believe that he is likely to benefit this society in a high degree, and that he will discharge the duties of President in a manner most satisfactory to this society. (*Applause*.) Gentlemen, Lord Wharnccliffe is a man of very large possessions within your county—he is a man engaged very much in the arrangement of its business—confidently engaged, I believe, in the concerns of the county—and in all those transactions I believe he has always shown his qualifications for business to be very great;—this being the case, and his lordship having stated his readiness to undertake the office of your president, I feel that he will perform the duties of that situation as efficiently as any other duties which have come under his management. (*Loud applause*.) I feel confident that you will have everything in the way of business conducted agreeably. (*Cheers*.) Gentlemen, it is desirable that the President of the Yorkshire Agricultural Society should be a Yorkshireman of large possessions—it is necessary that it should be so—and therefore, gentlemen, I am sure that when you entrust this office to Lord Wharnccliffe, you will have done that which is most likely to increase your prosperity—which is most likely to insure that increase in your members, and your influence, which you have heretofore experienced, and which it is my firm belief you will continue to do. (*Cheers*.) Gentlemen, I beg to propose the "Health of Lord Wharnccliffe," the president elect. (The toast was drank with three times three and loud applause.)

The NOBLE PRESIDENT shortly afterwards again rose and said—I have now got through the list of toasts which were given to me this day by the committee, but I think, that as we are now sitting together, I shall not be wrong in proposing one toast more—it is, "Success to the society's meeting next year, at Hull." (*Cheers*.) Our success depends of course upon our own exertions, and hitherto we have been successful, and I have no doubt but the meeting at Hull, next year, will be equal to any we have yet had. (*Applause*.) A gentleman has stated that we shall have the benefit in the conveyance of stock of a railway communication, and there is also a water communication which will make Hull one of the most advantageous places for the meeting that is to be found in the county; and that, consequently, the

show may be expected to be one of the largest. (*Applause*.) In addition to this, Sir E. Vavasour says, that Yorkshire ought to take the lead in agriculture; but I thought when the honourable baronet made this statement, that I heard somebody dissent from it. I do not know whether that person is a Lincolnshire man, but if he entertains any doubt, why let him try what he can do next year. (*Laughter*.) I am glad to see that interruption—I am glad to witness a spirit of emulation going forth, and I hope we shall all see the effects it will produce—we shall see, I trust, what effect this spirit produces on a town possessing the advantages of railway and water communication. The noble lord again proposed the toast, which was drank with loud applause.

The noble chairman then retired, and the company soon afterwards separated.

ROYAL BOTANIC SOCIETY OF LONDON.

—At the usual meeting of the society, held on Tuesday, Benjamin Bond Cabell, Esq., in the chair, after the election of several new fellows, there was read, by Mr. George Thurtell, a highly-interesting and important paper upon the growth and pruning of forest trees, which was clearly illustrated by numerous specimens brought from Holkham, the seat of the Earl of Leicester, showing the advantage of a natural over artificial pruning. Having given a general account of the growth of trees, both as solitary individuals and as the collective members of forests and plantations, he deprecated the use of close pruning, instancing from the specimens he exhibited, that where the excision is made decay inevitably takes place, and that while nature conceals the wound by forming fresh wood over it, the unsound portion about to become the nucleus of future dissolution, is inclosed within the body of the tree, and thus, that which has the outward appearance of firm and healthy timber, may be in such a state of rottenness in the interior as to be incapable of supporting any ordinary weight. This was proved in a communication which he had received from the late Lord Suffield, who mentioned that in some buildings he had erected, the rafters had fallen in; here the inside of the wood was rotten, the marks of the saw being distinctly visible within the sound outside, plainly proving that close pruning had been used. By natural pruning Mr. Thurtell explained, that when the lower branches of a tree had performed the duties assigned to them they gradually die off, the tree thus, it may be said pruning itself; and, contrary to the effects of close pruning, in this case, no decayed wood was embedded in the new formation of the timber, but all was healthy and sound. In conclusion, he begged to call the attention of the proprietors of woods and forests to a subject which was so important, not only as regards the landed interest, but our national wealth.

THE SLEEP OF PLANTS.—The sleep of the vegetable differs in one respect from that of the animal, that it is not caused by exhausted powers; but when light, which acts as a stimulus, is withdrawn, then the stalks of compound leaves hang back and fold their leaflets together, or the leaves droop over the flowers, or cover the fruits so as to shelter them from the cold dews. This was termed by Linnæus the sleep of plants, and said by him to be analogous to the action of spreading the wing, by which some birds shelter their young during night. It is generally thought that Linnæus's term is somewhat hyperbolic; but that the cessation of the stimulus of light and the constrained position of the flower and foliage may be advantageous to the vegetable constitution in a way similar to that in which it is beneficial to the animal system. Sir James Smith remarks, that as the infant requires a fuller measure of sleep than is needed by the man, so the young plant is more thoroughly closed during night than the older one.—*From Flowers and their Associations.*

THE MODE OF CULTIVATION ADOPTED ON STINCHCOMBE FARM, BY MR. DIMMERY.

By JOHN MORTON, Esq.

(From the Journal of the Royal Agricultural Society.)

This farm consists of 200 acres of arable land, and although Mr. Dimmery, the tenant, rents another farm adjoining it, which consists of about 200 acres of meadow and pasture land, it is my intention to give an account of his mode of cultivating Stinchcombe farm only; the other land being used for fattening his stock of oxen, and producing hay and pasture for his sheep and working cattle. The arable land is situated on the south side of Stinchcombe Hill, which projects from the main body of the oolitic formation into the vale or low district of the county of Gloucester, and is much celebrated as affording a most beautiful and extensive view of the vales of Berkeley and Gloucester, the Severn, and the Bristol Channel. Around the south side of this hill the lower oolite assumes the form of a low terrace in front of the hill, and at least 300 feet below the top of it.

Stinchcombe farm is situated on this low terrace, and is about 150 feet above the level of the Severn. The soil of the upper part of this farm next the hill is composed of the *débris* of the oolitic rock, and is dry gravel, of little value, but all below this on the low terrace is of a good friable texture, partaking of the nature of the sub-soil or lower oolite on which it rests, and is well calculated for the production of barley and oats; it is neither too strong and adhesive for turnips and potatoes, nor too light and soft for the production of wheat under proper culture. This farm is about 16 miles from Gloucester, 25 from Bristol and Cheltenham, 4 from Berkeley, 3 from Wotton-under-edge, and 2 from Dursley.

ROTATION.

The production of the largest crops of the best edible kinds of potatoes, and at the least possible expense, being the principal object on this farm, Mr. Dimmery has found the course of cropping which he has adopted after an experience of upwards of 40 years to answer the best. The first year he takes turnips, the second year potatoes, and the third and last year of the course he takes wheat. About one-third part of the wheat stubble is sown to winter vetches, which are eaten off the ground by sheep, and as the ground is cleared it is prepared for a late crop of turnips, so that the whole of the land which was wheat is sown to turnips the following year. The turnips are all consumed by sheep folded on the ground in the usual way. After the turnips potatoes are planted on the whole the next year. To this rotation most farmers would object, as a crop of barley might be taken between the turnips and potatoes, and also from an absence of a crop of clover in the course; but it will be seen in the detail that in this course for 12 years there are 4 crops of wheat and 4 crops of potatoes, both of which are the most valuable articles a farmer can produce from the soil, and only four preparing or fallow crops. The land is always kept in the best state of culture, and its productive power is never diminished by any of the crops which are taken, nor does it require in any one year any additional labour to clean it from weeds. The expense, too,

of this course of cropping for 12 years is perhaps not more than that of the best system adopted by our most scientific practical agriculturists, in whose course alternate crops of corn and green crops prevail; by this course, also, a greater quantity of vegetable and animal food for the use of mankind is produced than can be grown in this climate upon soil of the same quality under different management.

VETCHES.

Soon after the wheat is harvested the stubble is cut and carted off the ground before the potato harvest is begun. About 20 acres, or one third part of the wheat stubble, is prepared for winter vetches. One ploughing only is necessary, and about 3 bushels of vetches to the acre are sown broad-cast, and the ground is well harrowed to cover the seed. The cost of the seed and the expense of once ploughing and of two or three single turns of the heavy harrows are the whole expenses attending the cultivation of this crop: nothing more is required beyond the keeping the field shut up from stock during the winter and spring months. Mr. Dimmery thinks that the land very soon gets tired of growing vetches, and as he therefore takes this crop on only one-third part of the land which is intended for turnips, and his rotation being only a three-course shift, the portion of the land which is required for this crop does not come round for vetches oftener than once in nine years. The value of the crop of vetches which these 20 acres produce as food for sheep is very considerable, and can easily be ascertained from the amount of stock which it keeps. About 340 ewes, 340 lambs, and 170 wethers are generally put on this crop about the second week in May, and are kept upon it till the first of July, or till the crop is all consumed. This amounts to about 7 weeks' keep for a flock of 850 sheep, or at the rate of about 5 or 6 sheep per acre per annum, which may be said to be free of all expense beyond the cost of the seed, as the land does not undergo more expence in preparing it for the turnip crop than if it had not been sown to vetches, and the manure left by the sheep, with what additional dung can be procured, always produces a good crop of late turnips.

TURNIPS.

As soon as the wheat stubble is all carried off the land, the sheep are brought from the pasture land where they are fed by day and folded on the land intended for turnips. Mr. Dimmery prefers folding the sheep on the land before it is ploughed, as they lie much drier on it. As soon as the teams can be spared, either before, during, or after the potato harvest, that part of the turnip break intended to receive the stable-yard manure is ploughed, and that part which is folded by the sheep is ploughed as it becomes ready. The second ploughing is performed early in spring, generally in February and the early part of March: there is nothing particular in the preparation for this crop, except that from the shortness of the rotation and the two cleaning crops in it, the land never requires to be ploughed for the purpose of eradicating weeds, but only for pulverizing the soil and bringing it into a good tilth. For this purpose the roller is frequently used after the land has been ploughed, and before the drags are applied the land is always rolled to break down or bruise the furrows that they may have a greater effect, and get down to the bottom of the furrows; and when the land drags up in lumps it is again

rolled before the second dragging. This is the most effectual method of completely pulverizing the soil; the harrow is very seldom used in effecting it; indeed it is very seldom used at all on this farm, except in harrowing in the turnip seed. When the land is properly prepared for the crop, all the dung that can be collected is carted on it, and is ploughed in with the last furrow; that for Swedish turnips in May and June, and for the other in June and July, and that which was in vetches as soon as the land can be got ready after they have been consumed by sheep. The whole is generally finished about the middle of July. The turnip seed is always sown broad-cast on this farm. The whole of the crop is consumed by sheep on the ground, which are folded in the usual way, receiving along with the turnips a sufficient quantity of hay supplied from the grass farm. The sheep are generally put on the turnips in the end of October, and are kept on them till near the end of the following April; all the land is either manured by the fold, the dung carted from the yard, or by the consumption of the crop of vetches by the sheep. The turnips produced after the vetches are generally the greatest crop. Mr. Dimmery frequently sows Swedes after them; indeed he prefers Swedes to any others, and it is only for early consumption that he sows the common sorts at all. He only hoes the crop once, which is carefully performed so as to separate the plants to a proper distance. He does not require to hoe for the purpose of destroying the weeds. The expense of this crop may be reckoned at three ploughings, two rollings, five draggings, and two harrowings, besides carting all the manure raised on the farm. The land being always clean, the crop of turnips never fails. They are universally a good crop; the 66 acres are equal to keep from 16 to 20 sheep per acre, from the end of October to the end of April, which is at the rate of 8 to 10 per acre per annum.

CABBAGE PLANTS.

There are generally between two and three acres of turnip break, or field, sown with cabbage seed for plants for the autumn and following spring; the preparation for which is the same as for turnips, with the exception of an additional ploughing and harrowing being given. The seed is sown in the month of August, and the plants are pulled to supply the demand. Mr. Dimmery raises his own cabbage seed, and therefore can always warrant his plants to be the best of their kind; he only raises two sorts, the early York and broad Battersea. The seed of these are mixed together before sowing, and in drawing them for sale they can easily be distinguished; they are sold from 8d. to 1s. per hundred. From 150,000 to 200,000 have been sold in a season. All those which remain on the ground in May are eaten off by the sheep, and the land comes in its course for potatoes. Although the return from this crop is great, yet the expense of weeding and pulling the crop, tying them up in bundles of sixty each, and carrying them to market, is also great. Mr. Dimmery gives an allowance to those who retail them, and thus saves all the expense attending marketing. His kinds are so well known, that the most of them are sold on the ground to people who come for them: they are pulled up by men and women, who tie them up in bundles as they are wanted.

POTATO CULTURE.

Preparing the Ground.—As soon as the sheep have consumed the turnips off a considerable part of

the field, the land is ploughed, to cover the manure left on the surface by the sheep, and to prevent it from being either washed away by the rains or evaporated by drought. This is performed by the ox teams, the horses being at this time of the year employed in hauling out the potatoes to market, and other work on the road. After this ploughing, the land remains to the end of March or the beginning of April. If there has been frost to pulverize the surface, another ploughing is not necessary, and the heavy drags, loaded with blocks of timber, and worked with six oxen, go over the land twice to a place, loosening the whole of the furrow slice. The land is then rolled with a heavy roller, to bruise all the lumps brought up by the drags, after which it is again dragged in an opposite direction. If the land works well, it will do for planting after being again rolled; but if there has been no frost, or if the winter and spring have been wet, and the land has got soured by wet, or baked hard by drought, after the first ploughing, it is then rolled by the heavy roller to crush the surface, that the drags which immediately follow may have a greater effect and get deeper into the ground. I would here observe that Mr. Dimmery has a perfect knowledge of the use of the roller as a most efficient implement in pulverising the soil. I have never seen the roller so much used on any farm as on this. The heavy drags, loaded as before described, follow the roller; the land is again rolled, to crush the clods raised by the drags, and the field is again dragged in an opposite direction; it is again rolled the third time, and is ploughed again, if necessary, and rolled, dragged, and rolled till the whole of the furrow slice is so completely loosened and pulverised, as to be easily formed into drills by a hoe. The harrows are never used on this farm, for there are no weeds to shake out, and Mr. Dimmery says his object is not so much to reduce the surface as to loosen the whole of the soil to the depth at which it was ploughed, and the greater this depth the better it is for raising a crop of potatoes.

Seed.—The varieties selected for cultivation are those which, from long experience, have been found to produce, not only good crops, but also potatoes of a quality and flavour suited to the tastes of those who consume them. Four kinds are cultivated for human food—the mossys, an early, round, white potatoe, of good flavour, rather yellowish within. Of this sort a small quantity only are planted; they are ready about the end of July. The round black, or black skin, very white within, mealy, and of excellent flavour, keeps good from October till the end of May; and the magpie, or red apple, which keeps the longest of any, is of excellent flavour and very mealy. This last sort will keep good till the mossys, or early potatoes, are ready the year following. Besides these, the white flat is a very prolific, mealy potatoe, preferred to all others by the inhabitants of Gloucester. The greatest breadth is planted with the black skins and red apples, and these are planted on the best land, the white flats on the poorest soil. In selecting the seed, great care is taken to pick out those of the true kind for planting; the seed or sets are taken from the middle sized potatoes, and they are generally cut in two, the principal object to be obtained being the greatest quantity of good edible potatoes not of the largest size, otherwise the largest potatoes would be selected for seed, and the tops of these only cut off for sets. It has been found that the tops of

large potatoes produce the greatest crops of the largest sized potatoes. Many people think it necessary to change their seed every three or four years, at least, and particularly their potatoes, as this plant, they say, degenerates more than any other; the seed potatoe on this farm has never been changed, except once about thirty years ago, when the crop was blighted by some cause, which induced a change at that time; Mr. Dimmery then got new seed from Dumfries, in Scotland, and these he has continued to cultivate without any symptoms of degeneration or deficiency of crop.

Planting.—Mr. Dimmery has found by long experience that early planting is attended with great risk, not only from the frost injuring the young shoots when they come above ground, which, being full of sap, are destroyed by the slightest frost (the potatoe being the first of all cultivated plants that are injured in that way), and the check which they thus receive to their growth is most injurious to the crop, reducing it in quantity from ten to twenty per cent., but because that when the potatoes are early planted, the spring rains solidify the earth around the plants, and prevent the fibres from running in the earth, or create a much greater expense in hacking or hoeing the ground, to give the degree of looseness necessary to secure a full crop. Early planting, therefore, is always avoided on these accounts. This operation begins on this farm about the 20th of April for the early, and the 20th of May for the late sorts (the ground being previously well pulverised and loosened to the depth to which it has been ploughed). The ridges being a perch in width, drills are formed across them, and the operation is performed in this way:—a man with a heavy triangular hoe, about four pounds in weight, something in the shape of a mason's trowel, but considerably broader, with a handle about two feet and a half long, begins on one side of a ridge, by making a hollow groove or drill across the whole of its width, till he comes to the other furrow. This he does by repeated strokes of the hoe into the earth, moving backwards after each stroke, drawing the hoe and the earth with him, and then lifting the hoe to make a fresh stroke and a fresh movement backwards. This operation is repeated till he arrives quite across the ridge to the furrow between the ridge he is operating upon, and the one adjoining it; he then turns about, and makes a fresh drill at the distance of twenty-two inches from the one last made, till he comes to the side of the ridge where he first began, and proceeds in this way till the whole ridge is formed into drills, at the distance of twenty-two inches apart, and about six inches deep from the edge of the earth raised up by the operation, not, however, more than three inches into the ground, about six inches wide at the top and about two inches at the bottom. No line is used to make the drills straight; the workman, from long practice, performs the work without one, and succeeds in making them not only straight, but at equal distances. This work, it must be observed, requires considerable force. The weight of the hoe, and the shortness of the handle, force the person working with it to use it in such a position of body as enables him readily to employ the whole of his strength to the best advantage. His body is bent forward, the handle of the hoe between his legs, and his labour is very much like that of a carpenter hewing a spar of wood with an

adze, only he makes the strokes, not so much by lifting the hoe high above the ground as by pressing it into the earth by the strength of his arms, added to the weight of his body. As the workman is proceeding with his work on this ridge, others are proceeding in the same way with the other ridges adjoining, but, instead of forming the drills in a straight line across all the ridges, each of them is designedly made to begin and terminate in the middle of the space between the drills on the ridges on either side of it, and this plan is universally adhered to throughout all the field. This may be thought a slovenly and irregular mode of proceeding with the work, and certainly it does appear so; for the field would look much better if the rows were in a continued straight line across the whole of it; but when the reason for adopting this mode of proceeding is explained, it will be evident that Mr. Dimmery has the best of all reasons for using it—viz., the obtaining by it an increase of produce. Every one, at all acquainted with agriculture or gardening, must have observed that potatoes, or any other plants, produce a greater crop when separated from each other by a considerable distance than when they are planted near each other, and that the outside plants of a row are more productive than any other plant in the row, every other circumstance being the same. Having observed this to be universally the case, Mr. Dimmery has adopted this plan of terminating the rows of each ridge precisely in the middle of the space between the rows of the adjoining ridges, and by this mode of proceeding he gets an increase of upwards of five per cent. more than if the rows were in a continued straight line across the whole field. The drills being formed, as above described, a man follows with a basket of soot, and sows it in the bottom and sides of the drills with his hand, walking up the middle of the ridge, and throwing first a handful of soot to the right and then a handful to the left, at the rate of about twenty-five bushels to the acre. The potatoe sets are then planted by women and boys, in the bottom of the drills, ten inches apart, and as the seed is deposited in the drills, a man follows with a hoe, about eight inches wide, and covers the seed by drawing the earth from the space between the drills, covering the potatoes which are planted by raising the earth higher over than it is between them. The earth being very loose, this is very easily accomplished. By this mode of covering it will be perceived that the whole of the soot does not come in contact with the seed, but is so placed as to give nourishment to the young roots. The whole of these operations of forming the drills, sowing the soot, planting the seed, and covering the potatoes, are going on at the same time. I have seen 8 adjoining ridges in progress at the same time; 8 men with triangular hoes making drills, 1 man to each ridge; 2 men sowing soot, 4 ridges to each; 8 women, 3 rows behind them, planting the seed; 2 men or boys carrying the potatoes to the women, and 8 men covering them in; 2 carts hauling the potatoes from the barn, where the sets are prepared; and 2 women filling the carts from the barn: thus 32 people and 4 horses are in constant and full employment, until the whole crop is put into the ground. The head lands are planted across in the same way as the other ridges, and the whole of the operation of planting is finished, and the field shut up till the plants begin to appear above ground. The forming of the drills, sowing the soot, planting

and covering the seed, only cost 6s. per acre, exclusive of cutting the sets, carting them, and carrying them to the planter, and of carting the soot. This seems certainly very little, but it must be recollected that the land is very loose, smooth, and finely pulverized; the price is the same now as it was during the war; there has been no alteration for the last forty years. To this, however, should be added the price of 3 quarts of beer to the men, and three pints to each woman and boy per day; and the wages which the men earn are 9s., the women 4s. 6d., and the boys 4s. per week; 16 men making the drills and covering the seed, and 8 women planting the seed, can easily finish 5 acres a-day with 45 sacks of seed.

Hoeing.—Hoeing (or *hacking*, as it is here called) is performed by the same peaked hoe which has been described, and used in forming the drills. As soon as the plants begin to show themselves above ground, this operation is begun, and is performed by men working with it in the same position as when forming the drills, only he is now under the necessity of lifting it up and making repeated strokes with it into the ground, thereby moving and loosening all the ground between the rows of plants, and also between the plants in the rows, taking care not to disturb or injure the plants; this work is performed by men at the rate of 8s. per acre, with 3 quarts of beer per day to each man.

Earthing up the Potatoes.—When the plants get from 4 to 5 inches above the ground, the earth is drawn up about them on both sides of the row. This is performed with a hoe about 8 inches wide; the plants by this operation are nearly covered, and it is found that the higher the earth is drawn up about the plants, the greater is the produce; it is therefore necessary to be particular in the performance of this work, as much depends on its being done properly. None of the plants should be covered, as this checks their growth, and gives their neighbours the start of them. In performing this part of the work, it must be observed that the earth is drawn up around the ends of each row, which projects in between the rows of the adjoining ridge, and no loose earth is left either in the furrows between the ridges or between the drills. In performing the whole of this operation, the object is to lay as much loose earth close round the stem of the potato as possible, that the runners on which the potatoes grow may not be obstructed in their growth in any direction; the expense of thus earthing up the potato is at the rate of 6s. per acre, with 3 quarts of beer a-day to each man. The field is now shut up till the time of harvesting the crop.

Harvesting, or taking up the crop.—This work is generally begun about the beginning or end of October, except the early sort, which are taken up to supply the demand, or whenever the haulm or leaves of the potato have withered and begun to decay. The first part of the process is to pull up with the hand the whole of the haulm or stalks of the potatoes, and lay them in parcels on the ground; any potatoes that come up with the stems in this operation are shaken out upon the ground; some hands begin this part of the business first, to clear the ground for the diggers to follow. This work is always begun at the lowest part of the field. The potatoes are all taken up with the spade, and this is performed by pressing in the spade with the hands (the foot never being used as in digging) behind a portion of the row, and scattering the earth and the potatoes he lifts up before him; this he does by turning the spade as he spreads;

the whole several feet from him every time he lifts a fresh parcel of the drills, and if he sees any potatoes remain in the ground they are twitched out by a sharp turn with one of the corners of the spade. Women and boys are employed in picking up the potatoes into baskets as they are thrown out upon the surface, and 1 or 2 men emptying the baskets into the cart or waggon, which takes them off the field to the storing-place. There is the same method adopted in taking up the crop as there is in planting it; there are 2 men to each ridge, with spades to lift the potatoes out of the earth, and spread them before them on the ground which they have already cleared. Each man works at his own side of the drill, 2 women or boys with a basket picking up the potatoes as they are thrown, besides a man for every four ridges, to empty the baskets, as they are full, into the carts. That the sorts of potatoes may be kept free from mixture, Mr. Dimmery gives to those employed all that run from their kinds, and therefore those employed on every ridge have a bag, into which they put all the produce of those which are not of the true sort and which is divided every night amongst those employed. From 40 to 50 people are employed in this work while it lasts; it is generally accomplished in about 3 or 4 weeks, if the weather is favourable. The men receive 9s., the women 4s. 6d., and the boys 4s. each, per week, with an allowance of beer. The whole expense of harvesting this crop, per acre, including the expense of the harvest-home, when a supper and plenty of beer and cyder are given to all the people who have been employed in the work, has in no year exceeded 21s. per acre. The average produce of this crop may be stated at 60 sacks, of 280 lbs. per acre, of good saleable, edible potatoes, of the magpie or red-apple; 70 of the round black skins and mossys; and of the white flats about 80 sacks; besides the broken and small, and those kept for seed, which amount to about 20 sacks per acre more.* The value of this crop, like every thing else, is regulated in some measure by the price of wheat, being about the same for a sack of potatoes weighing 280 lbs., as the price of a bushel of wheat. As to the relative value of the different kinds, Mr. Dimmery reckons that when the magpie or red-apple and early potatoes sell at 8s., the black skins, and white flats are worth 6s. per sack. The common mode of raising a crop of potatoes is by applying a large quantity of dung in contact with the seed or sets. This plan has been suspected of producing a disagreeable flavour in the potato; as however, we have said before, Mr. Dimmery's object being to produce the greatest quantity of good flavoured, edible potatoes, he has adopted the mode of applying all the dung to the turnip crop, and as this crop is consumed by the sheep, their dung is dropped regularly over the whole surface, and is intimately mixed with it by the succeeding preparation. The whole of the staple, to the depth of the furrow slice, is thus enriched, not only with all the dung applied to the turnips, but also with the produce of the whole turnip crop consumed by the sheep, without any portion of the manure coming in contact with the plant.

Storing the crop.—The kinds which are for im-

* That is an average (including chits and seed) of 90 sacks; equal to 11½ tons per acre; which is a very large produce, particularly if it be considered that the sorts planted are of "edible potatoes" for the table, and consequently not of the size of those usually grown for the feeding of cattle. F. BURKE.

mediate use are put into a large house or barn for the purpose, and the carts which fetch them from the field are put back into it and emptied; these are thrown together in parcels, taking care not to mix the several kinds; each are kept apart by straw, supported by boards or hurdles, and are easily taken out and carried to market, being only covered with straw. In the time of continued frosts, a fire is lighted in the house in the after-part of the day, which prevents the frost injuring the potatoes. Those which are to be kept till the spring and summer, and these are the most valuable kinds, are stored in a corner of a field, near to the road, and generally in the field which is to be in potatoes next year; they are put into heaps of not more than 20 sacks or 2½ tons each. This size is not so much for the convenience of moving one of these heaps at a time in a waggon, but it is found that they keep much better in heaps of this size than when they are larger; for when there is a great quantity put together they are apt to heat and spoil, and many of them rot. To prevent this, in the barn where a great quantity are put together, it is found necessary to separate them into small parcels with hurdles and straw, and turn them over now and then. These heaps are formed on the surface of the ground; the potatoes are piled up in the form of the roof of a house, they are then covered with straw, and about 2 feet from the potatoes, all around, a trench is dug, the earth taken from which is placed upon the straw about 8 inches thick, and beat close with the back of the spade; the whole of the surface of these heaps are then covered with the potato-haulm which was brought from the field, to keep out the frost and rain. The expense of covering the heaps with earth is 1s. 6d. each. I have seen 100 of these heaps in the corner of a field, so close together that the whole of the surface of the soil, to the depth of the furrow, has been moved between them, to cover them.

Preparing Potatoes for market.—In preparing the potatoes for the market, iron sieves, having meshes about 1 inch square, are used for separating the small potatoes, and carrying off any earth that may adhere to those which do not pass through the sieve. Wooden shovels, such as are used for turning malt, are used, and also iron shovels, made of round rods of iron, welded in the front to a flat piece of iron, forming the mouth, and on the back to a stronger piece of iron, to which the handle is fastened by a hose; these round rods are at the distance of about an inch from each other: the object of thus forming a shovel is not only to make a large, light, efficient instrument, but to allow the loose earth to drop through it, as the potatoes are lifted with it, from the berry or barn into the sieve. When the potatoes are to be prepared for the market, a sufficient number of hands are employed; the waggon is put in a proper place, and a man, having a sieve in his hand, a shovel full is put into it by another person, and he gives it two or three turns, and then empties it into a basket, which is a measure equal to a third part of a sack. Any broken or spoiled potatoes are picked out of the basket, during the time they are filling it from the sieve, by a boy, and when the basket is full, a man empties it into a waggon; the small potatoes which go through the meshes of the sieve are, from time to time, taken by a woman or boy, and separated from any stones or earth, and put into a place by themselves, either for seed or to be sold for the pigs. A man with a shovel, and 2 men with sieves, a boy, and a woman, are employed in thus preparing the potatoes from one pit at a time. The po-

tatoes are thus prepared for the market: the berries are never opened except for the purpose of taking them to market, unless in the spring, when they begin to sprout, when they are turned over in the way as already described. When they are prepared for the market, several turns more of the sieve is given to them, for the purpose of bruising the sprouts. The expense of this method of turning the potatoes is very trifling; 12 persons, men and women, can easily do 3 berries, or 60 sacks, in a day, or 4s. 6d. each pit of 20 sacks.

WHEAT.

As soon as the potatoes are all taken up, the field is dragged over once in the direction of the ridges; the edges of the drills, which may have been neglected by the spade in taking up the potatoes, are by this operation levelled, and any potato-haulm that remains is gathered up and carried off the ground; the wheat is then sown on the surface after the drags, and ploughed in; this is preferred to the common way of ploughing the land first and harrowing in the seed after. Mr. Dimmery's reason for this is, that the land after the potato crop is left so loose that it is necessary to get a good clod on the surface if possible. By this plan the firm earth at the side of the potato-drills is lifted up by the plough, and left on the surface. A team easily ploughs in an acre a-day, and a man and a boy follow with spades to clean out the furrows, and level any of the ground that may be left uneven. The quantity of seed is from 3½ to 4 bushels per acre, according to the time of sowing; the later it is sown the more seed is required. Mr. Dimmery thinks that farmers lose much by not putting seed enough into the ground. In the spring, about the month of March, the wheat receives a dressing of soot, at the rate of from 25 to 30 bushels per acre. The crop is reaped and stored in the usual way in the rick yard; the average crop is from 28 to 32 bushels per acre, but he has often had 40 bushels per acre; it is always clean and of good quality; there never was any smut seen on this farm; the reason, Mr. Dimmery says, is because he always sows *newly-threshed seed, the produce of the previous year*. The expense of preparing the land for this crop is only once ploughing, 4 bushels of seed, and 12s. to 15s. worth of soot (24 or 30 bushels), so that in the system adopted on this farm, the crop of wheat, which farmers in general reckon the most valuable of all their produce, and for which all their previous course is only a preparation, really costs Mr. Dimmery nothing, nor is he in any anxiety about the preparation. The crop of potatoes being his principal object, by the plan which is here adopted the land is left in the best state that such land can be left in for receiving the seed. All the wheat-straw is made into haulm (as it is called), for thatch, the value of it depending on the separate straws being kept whole and sound; the wheat is not thrashed in the common way, in the straw, as this would injure it for thatch, but it is prepared in the following way:—a cord is made fast in some elevated part of the barn, upon the wall or in one of the great doors, and a sheaf of the wheat in the straw is parted into as many parcels as a man can grasp with both his hands; he then places this parcel with the ears on the ground, holding them loosely in his hand, lifting up the parcel repeatedly, and letting them all drop to the floor so as to get the ears all even together: when he has effected this, he then takes hold of the parcel, directly below the ears of corn, and

takes it to the cord, and fastens it around close to the ears by a single hitch; he then, with a long-toothed comb, with a single handle like a rake, combs all the straw below the hitch, to get out any ears of wheat that may still remain, and also all the broken straw out of the parcel, searching for them by spreading out the straw with his hands; the parcel is then taken from the cord to a separate place on the floor, and the ears of wheat are cut off from the straw; the straw is then put in a place detached from the ears, until a quantity sufficient has been collected to make a bundle. The bundle is tied up with a strong band made of straw; each of the bundles is about 40 inches in circumference, and weighs about 30 lbs.; they are sold for 10s. per dozen. The expense of making the haulm is about 1s. 9d. per dozen, and of thrashing out the wheat from the ears is about 4d. per bushel. Every day's work is finished by carrying out the bundles, and thrashing out the wheat from the ears that have been cut off, and cleaning the floor for the next day's labour. There is an average of 2 bundles of haulm for every bushel of wheat, besides the broken straw and ears, which may in general be equal to 25 or 30 lbs. per bushel more; thus about 60 bundles of haulm is made from the straw of each acre, producing 2l. 10s. per acre for the straw, besides the price received for the wheat, which varies according to the demand.

MANURE.

The quantity of dung raised on this farm by the working cattle and the pigs, which consume the refuse potatoes, is not great for the extent of land in arable culture, particularly as nearly all the straw grown on the land is sold for thatch. To fill up this deficiency, Mr. Dimmery used to buy all the dung he could, and whenever his teams went out with a load of potatoes they brought home a load of dung; but this he has discontinued for nearly 30 years, and, in place of farmyard dung, he has found a most valuable substitute in soot, the carriage of which is not one-twentieth part of the expense of hauling the dung he used to buy. Soot, therefore, is an object of great importance to him, and as the carriage of it is light he fetches soot on his return when he takes potatoes to market, either from Gloucester or Bristol, both of which cities he supplies; he has found that there is a considerable difference in the quality of soot, and this difference depends, he says, principally, if not entirely, on the length of the chimney producing it; the chimneys of Bristol being much longer than those of Gloucester the soot of the former city is of a much better quality than that of the latter. The general price of soot is 6d. per bushel at Gloucester, 120 bushels cost 60s., while he pays 5l. for 140 bushels at Bristol, and yet he prefers the latter as the best bargain. He has lately sent to Cheltenham for it, because he gets it at a lower price, although he has to haul it a distance of nearly 25 miles. The quantity of soot used on this farm is upwards of 3,000 bushels a-year, one-half of which is applied to the potato and the other to the wheat crop; it is seldom that it is applied to the whole extent of either of these crops, but wherever it is thought the application would be advantageous the expense is never saved. As there is a considerable variety in the quality of the ground, some parts of it receive a much greater quantity of soot than others, and this whether the crop is wheat or potatoes. We have not been able to obtain from Mr. Dimmery any idea of how the soot acts in producing

such effects, as it evidently does, both on the potato and wheat crop: the effect of it is particularly evident on the wheat, for, however sickly it looks in the spring, its colour and the vigour of its growth is changed in a few days after it has been applied. Soot is evidently a very powerful manure, and a portion of its charcoal is in a state in which it is capable of being rendered soluble by the action of oxygen and water; it affords ammoniacal salts by distillation; the effects, therefore, produced by it on the growth of vegetables may be owing both to the ammonia and the solution of the carbon of which it is composed; but the experiments made by Mr. Malcolm with soot, recorded in the first volume of the *British Husbandry*, p. 337, are most convincing, as proofs of the superior value of soot as a manure.

ESTABLISHMENT.

Mr. Dimmery directs and attends to the performance of all the operations of the farm that are going on; although there is a greater variety of labour in the system which he has adopted than there is on farms in general, the whole of the several branches are so distinct and separate from each other, that one is finished before it is time for the other to be begun. When there are a number of labourers employed together, it is of great importance to have the faculty of order; with this power the whole can easily be arranged, so that every one shall perform his own work without interfering with those that are near him. The industry of each thus acts as a stimulus on the others, instead of retarding the progress of their labours. There are constantly employed on this farm 8 men and 8 boys, whose business it is to work the teams of oxen and horses; there is also a shepherd, whose business it is to attend to the sheep, besides those employed in planting, harvesting, and marketing the potatoe crop, and those employed in harvesting and thrashing the wheat crop. The working cattle are 12 oxen and 4 horses, with a saddle horse; only 2 oxen are put to a plough, but a boy is employed to drive them, besides a man to hold the plough; thus 6 ox and 2 horse ploughs can be worked at the same time; this is strength more than equal for all the work that is required in cultivating these 200 acres of arable land. There are always 4 of the oxen turned off every year to fatten, and 4 young ones brought to supply their place in the team. These are all of the Hereford breed, as they are not only good workers, but also good feeders. In the winter, spring, and summer, the 4 horses are generally employed in hauling the potatoes to market, and fetching soot home; but as they cannot perform the whole of this labour, Mr. Dimmery hires teams to assist, at from 16s. to 1l. a day, for a waggon and team of 4 horses. This costs him after the rate of 8d. per sack for hauling the potatoes to market. During the time of preparing his land, either for the potatoes or turnips, he generally hires teams to carry out all the potatoes which the market demands.

STOCK.

Besides the 12 oxen and 5 horses employed in cultivating the farm, there is a flock of sheep, consisting of 340 ewes, 340 lambs, and 170 wethers; the old ewes and wethers being generally sold off about Michaelmas, in good store condition, or fatted for the butcher. The whole of these sheep are kept on the arable land, from the middle of October, on turnips, till the middle of April, or sometimes till the middle of May, when they are put to the vetches, which will keep them till the middle of July. If the vetches are not ready for them when they have finished the turnips, they are taken to the grass

farm for a short time, and after the vetches are all consumed they again return to the grass land, and are fed on the latter till the end of October. There are also a number of pigs kept to consume all the offal potatoes; the number is very uncertain, depending on the quantity of small or broken potatoes which cannot be sold; for it is a rule with Mr. Dimmery to dispose of all the offal potatoes, if there be a demand for them, instead of buying pigs to consume them.

On examining into the merits of the system adopted by Mr. Dimmery, we are struck with the shortness of the rotation, the absence of clover and all other green crops as food for sheep, except turnips, the succession of two fallow crops, and the sale of nearly all the straw, which reduces the quantity of vegetable and animal manure to be returned to the soil. It is said that when a crop is repeated in too rapid succession, the soil soon gets tired of it, and the produce of it is gradually diminished: this we know to be the case in some instances, on certain soils. Saintfoin, it is said, will not produce so good a crop on any land the second, as the first time it was sown; and it not only diminishes in quantity on every repetition, but it will not remain so many years in the ground; and some farmers say that there ought to be a period of 30 years, at least, before it should be again sown on the same land. Clover seldom succeeds on sandy loam, or thin hashy land, when often repeated; and at the distance of four years it frequently fails. Turnips, also, on light sandy soil, when repeated at short intervals, grow fingery and of little value. I think, however, there may be some other reason for these failures, as a good coat of clay or chalk on the Norfolk and Suffolk land, when it gets tired of turnips, and produces them fingery, has the effect of giving to the land the power of again producing good crops of this root, and at the same intervals, viz., once in four years. When land is well calculated for the production of wheat, it is very evident that it will continue to produce this crop for a much longer period than land that is not fitted for its production. I have seen on good strong wheat and bean land, 10 good crops of wheat produced in 20 years, with alternate crops of beans, clover and summer fallow; the last crop much better than the first, and the land become more fertile and productive by this culture than before; but we could not expect to have an increasing return if we were to adopt this mode of cropping with wheat on light sandy soil. Much, therefore, depends on the kind of land, whether it is best calculated for the growth of the particular crop that is grown on it. I have before said, that the soil of Stinchcombe farm is neither too strong for the production of turnips and potatoes, nor too light for the growth of wheat. Although the soil be well fitted for the rotation adopted, there may be something in Mr. Dimmery's peculiar method of working the land, in preparing it for the several crops, as well as in this succession of crops, which may prevent them from being injured by their rapid succession. I have been in the habit of riding over the farm ten or twelve times a year for the last twenty-five years, and I can safely say that, instead of a diminution in the crops there has been an increase, not only in the yearly return of each of the three crops grown, but also in the quality and fertility of the soil. It is universally allowed that the principal merit of the Norfolk system is the quantity of food it produces for sheep: it is a maxim in agriculture, that the greater the number of sheep that can be maintained on an arable farm, the greater will be the produce of corn per acre; this is evident to every agriculturist, as it is not only the cheapest but

the most profitable mode of bringing land into good heart. "If I can only get a good crop of turnips, I shall be sure of a good crop of barley and clover, and then the land will be in excellent condition for wheat," is the language of every farmer when he sets about to clean his land in good earnest, and prepare it for turnips. In this rotation there is only one-third part of the land that produces turnips as food for sheep; and if we place this crop in juxtaposition with the turnip crop, in the Norfolk four field system, it will not appear to disadvantage, nor will there be a less quantity of food for sheep produced on this three-field than there is on the four-field shift, if the clover on the latter is mown for hay, and not consumed green on the land by stock; for we must remember that there are four crops of turnips in twelve years in the three-course shift, while there are only three crops of turnips in the same period in the Norfolk system. The quantity of manure, therefore, which the sheep leaves while feeding off the four crops of turnips during the twelve years, is at least one-fourth more than that which can be left by the sheep while consuming the turnips produced by the Norfolk system in the same period. It is said that one acre of land is well manured by 200 sheep, when folded on it one week, or by 1400 in one day. Now, if we reckon an acre of turnips to produce food sufficient for 12 sheep for 6 months, we shall have the manure of upwards of 2000 sheep for one day left on every acre that was in turnips, and this dressing repeated every three years, besides the manure of the sheep while consuming the 20 acres of vetches, which is nearly equal to that of the turnips. This, I think, is at least equal to, if not a great deal more than all the manure that can be produced on a farm of land of the same quality under the four-field shift, when no manure is purchased. The succession of two fallow crops is against all precedent in the agricultural world, although a succession of two corn crops is too often adopted in every county of the kingdom, to the injury not only of the farmer, but also of the land; and it is the greatest difficulty to get the farmers to give up this, for the alternate system of cropping. To propose potatoes as the most profitable crop after turnips would be reckoned the height of madness, but when we consider the potato as the most valuable crop that can be produced, this must be a reason sufficient for adopting a system that produces the price of 70 or 80 sacks of potatoes, at the same time that the land is receiving the best preparation for a crop of wheat the year following. It is very evident that this course of cropping must keep the land perfectly clean and free from weeds, both annual and perennial; the perfect fallow given to the turnips, followed by the preparation for the potatoes, with the complete culture given to this crop, must eradicate every weed from the soil. All the energy of the soil, all the enriching and vivifying quality of the dung, the fold and the soot, which is yearly applied, has its full effects on the crops which are cultivated, instead of being dissipated by the production of weeds. We must acknowledge that nearly the whole of the produce being carried off instead of being consumed on the farm, and converted into manure to be again returned to it seems, at the first view, to be the most objectionable part of the whole system; but when we examine the whole of the detail, and find that, instead of a dressing of from 10 to 12 cart-loads of dung once in four years, which is all our best farmers can produce, that Mr. Dimmery gives first a dressing of soot to the potato crop, repeats it again the following spring to the crop of wheat; that all the manure he can raise is bestowed for the production of turnips

the year after; and that in fact his land is manured every year instead of only once in four; that besides the quantity of manure left by the sheep four years out of twelve, he buys yearly from 80*l.* to 100*l.* worth of soot as manure for his land, we cannot help feeling satisfied that there is much more than a compensation for the loss of the straw and the potatoes taken off the land. Indeed, from our observation of this management for so many years, we are convinced that the system adopted is one that ought to be well considered by every farmer in the kingdom, because, that by it the land not only increases yearly in its productiveness, but that it also produces more vegetable and animal food for man, and at less expence too, than is raised by any other system.

The quantity of human food raised on this farm, and the number of families it will yearly maintain, may be reckoned thus:—We have before stated the vetches to be equal to the keep of 5 sheep per acre, per annum, and the turnips equal to the keep of at least 8 sheep for the same period; these two crops will be equal to 4 ewes, 4 lambs, and 4 tegs per acre; of these 4 are sold yearly, which produces at least 300 lbs. of mutton. The potato crop being equal to from 60 to 80 sacks per acre of 280 lbs. each, is equal to 16,800 lbs. of good wholesome food, and, besides what is reserved for seed, there are at least 10 sacks per acre more of offal potatoes, by feeding pigs with which, if we can produce 10 lbs. of bacon per sack, we shall thus have 100 lbs. of animal food, in addition, from this crop. The average of the wheat crop may be taken at 28 bushels, each of which will produce 70 lbs. of bread; this crop, per acre, will be equal to 1890 lbs. of bread; there are, therefore, produced from each of these acres 400 lbs. of mutton and bacon, 1890 lbs. of bread, and 16,800 lbs. of potatoes.

The advantage derived by the community at large from this mode of culture is evident from the increase in the productive food for man, thereby not only supplying the deficiency, but diminishing the price, of the first necessaries of human life.

JOHN MORTON.

Chester Hill, near Stroud, Gloucestershire,
December, 1839.

ON DRAINING.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—In the Express of this week, a farmer north of the Tweed, asks for information respecting the draining of moss. In offering to him and others, through the medium of your journal, the following observations, I do not assume the principles to be novel, as another similar in some respects, will be found in writings on draining; but merely state the plans which I have found, under all circumstances, effectual. Before I observe on the course to be pursued, it will, I think, be better to state the peat mosses and bogs which I have drained, have been situated in the valleys of the south of England; where the cause of the bog (not taking into consideration any geological deductions from changes of surface) has invariably been, a confined body of water; the origin of which was, in most cases, and perhaps in all, many feet above the level of the bog. Mr. Lyell in his second volume of Geology, makes the following remarks on the growth of peat:—"The generation of peat, when not completely under water, is confined to moist situations, where the temperature is low,

and where vegetables may decompose without putrifying. It may consist of any of the numerous plants which are capable of growing in such stations; but a species of (*Sphagnum Palustre*) constitutes a considerable part of the peat found in marshes of the north of Europe; this plant having the property of throwing up new shoots in its upper part, while its lower extremities are decaying." Taking the above to be a description of the moss of your correspondent, I am induced to consider the plan proper for the draining of one sort of peat, to be also a principle applicable to any other.

The chief and primary object in draining peat is to ascertain the position, or nearly so, of the head of the spring or springs; these in the peats I have drained, which were of small extent, were very obvious, having generally found an elevation in the surface directly over the spring. Your correspondent states his moss to be level; there may still be some trifling elevations in the surface, or if not, perhaps he may observe parts of it to dry and burn in a different manner from the adjacent parts during very dry weather. The position of the adjoining land will also very frequently, if attentively surveyed, afford sufficient indication, and particularly so I should imagine in Scotland, where the primitive rocks prevail, the springs being less divided, and their sources easier ascertained on the tertiary strata. Having determined on the probable position of the springs, and considered the open drains and ditches required, a drain should be cut nearly on a level, about 3½ or 4 feet deep from the lowest point, and continued through the springs; or if the peat be extensive and the line of springs irregular, a main drain of the same depth should be cut from the same point in a parallel direction below, or at the side of the springs, making branch or side drains from it to each spring; or some springs may be cut through by the main drain, and others taken by their branches, as their position may indicate, the distance at which the drains should be cut, being entirely dependent on the probable number of springs. It should be noticed, though the surface may denote several springs, I have frequently by boring, and giving vent to that which from a greater elevation of surface appeared to be the principal, succeeded in draining several acres of peat. It will therefore be always advisable, after setting out the drains, to cut only such as are necessary for the draining of the supposed principal springs, leaving small turnings for the branch drains should they be requisite; every drain that does not lead to a spring, or a fresh body of stagnant water, being useless.

The kind of drain I have made use of is the covered stone drain, having an open conduit about four inches wide by five inches deep, which of course may be varied according to the quantity of water. To make a firm foundation to receive the stones, heath, gorse, or small bush-wood in its green state should be first laid, and trodden in well at the bottom of the drain, and stone broken rather finely put on it, with the smallest pieces or chip-pings of the stone over that, forming a plain surface which will do for either stones or tiles.

The drain for the stone will require to be 2, or 2½ feet wide at the top, and about 2 feet at the bottom, to allow room to set the stones in a proper manner; care should be taken that the side stones stand perpendicular, and well seated for the reception of the top or horizontal stones. The width of the drain for the tiles would partially depend on the size of the tile used; though as heaths, &c. will

be required for the bottom, it will be right to make it rather wider, that a more firm basis may be given to the tile. In filling up either the stone or the tile drains, I would recommend that the peat be laid immediately on them, care being taken that the stones are first sufficiently closed by adding a few small stones, and as soon as enough peat be put into the drain, that the rammer can be used with safety, it should be well rammed, and so continued at intervals to the surface. Much has been written about the drains being either filled loosely, or with small stones, to admit the water from the sides; but I am satisfied it is improper; they are less secure and durable, and by admitting the air the soil becomes so changed adjacent to the drains, that it will be impossible even in mixed, or more adhesive, soils to keep the water from filtering through. The depth to which the auger holes should be bored, will of course entirely depend on the position of the sub-strata conveying the water, which in all bogs that I have drained, is conveyed by the heading out of stone or porous strata, some very close to the peat, and some at considerable depths, varying from 15 to 60 feet; in some instances two or more thin porous strata may be passed by the auger before the main spring be tapped. The drains, after being prepared for the reception of the conduit-stones and well trodden on, should be left open till the silt which frequently rises up the auger-holes in considerable quantity is cleared away, or they will be liable to be choked up. I will not now enter into further detail, as it would occupy too much space; I trust I have written sufficient to illustrate the method, and if it should be the means of assisting in draining some of the most valuable land in the kingdom (provided marl, or clay and lime be afterwards applied), my object will be gained.

I am Sir, your obedient servant,

4th July, 1840.

AGRICULTOR.

ON THE SELECTION OF SEED GRAIN.

TO THE EDITOR OF THE FARMER'S MAGAZINE.

SIR,—Some observations by different writers lately appeared in your paper on the subject of seed wheat, and at the late Cambridge meeting some of the speakers again introduced and enlarged upon it as one of great importance, which it no doubt is. Having had considerable experience as to the proper *quality* of grain to be used for seed, and formed an opinion respecting it different from the generally received one, I will, with your permission, cast my mite into the treasury. If the doctrine to be advanced should startle any reader into an instant condemnation of it,—if it is likely at first view to be denounced and repelled as unsound, let such an one pause, and before he comes to a hasty decision, let him, if in his power, put it to the test of experiment—a fair unbiassed experiment, without a pre-determination to arrive at a certain result.

Some hints of the following nature were thrown out a few years ago, and appeared in a work conducted by the late Rev. Henry Berry. That gentleman, in a note appended to the article, certainly demurred to the correctness of the doctrine in its application to cattle and sheep. As applied to seed grain, he made no remark. It seems, however, to be equally applicable to both.

Perhaps a premium for the best essay founded on experiments made on this subject, would be well by any agricultural society.

Agriculturists, then, generally choose THE BEST samples of grain for seed which is procurable in their respective, or in distant neighbourhoods. The question is, is this practice—that of selecting the *primest article* for seed—a wise one, or might not an article of *secondary quality* answer better?

There appears to be a limit set by climate, cultivation, situation, and local circumstances, to the *quality* of the produce of the soil. All cultivated vegetables have a tendency to degenerate, but this tendency is more than counteracted by the cultivation bestowed, until they arrive at a degree of perfection beyond which it does not appear possible, by any cultivation, to push them; and if this is attempted a recoil is induced, and a degree of degeneracy and inferiority in the produce appears to be inevitable. This is perhaps particularly the case in annual and biennial plants. Suppose a very prime sample of wheat is presented to us, such as might induce a farmer or corn-factor to pronounce it one of the best which he had ever seen. "An admirable article *for seed*, sir, I assure you." Softly, my good friend, perhaps you mistake. The presumption is, that this fine grain grew on land of the best quality, which was prepared in the best possible manner for it, that the circumstances attending its growth, ripening, harvesting, &c., had been particularly favourable, and that it had, in fact, arrived at the utmost perfection which it was capable of attaining. Now, if this fine grain is used as seed, what will be the result? of what quality will be the produce? Will it not be found to have degenerated, to be much inferior to the seed used? Improve it cannot—that it will remain stationary is just possible, but that it will go back is almost certain.

When grain is used which has reached the maximum, wheat weighing, say 66lbs. per bushel, barley weighing 58lbs. per bushel, oats weighing 48lbs. per bushel, is the produce reaped equal in quality to the seed sown, or is it not always a few pounds, and often a considerable number of pounds lighter? The plants appear to be constitutionally incapable of producing an equal to that grain from which they sprung, because it had attained that degree of perfection beyond which it could not possibly go, and therefore retrograde it must for a season; but having now room, it will advance again the following season, if climate, soil, and circumstances are favourable; should these be unfavourable, it will continue to retrograde.

If this doctrine is correct, it follows, that to raise a *first-rate article as produce*, we must use an article of *lower quality as seed*.

My attention was first directed to this subject in the year 1830. Having that year a small field to sow with wheat, for which I had no seed left, I procured as much from a neighbour. The quality was very middling indeed, considered as *seed* wheat, so much so, that the farm servants who picked and sowed it, &c., could not avoid regretting and grumbling during those operations, that such inferior seed should be sown on such fine land. The field had been well prepared for potatoes, had borne an excellent crop of them, and was in prime order; the soil a clayey loam. I was not at all satisfied myself with the course I was pursuing, but I had no alternative at hand, and sown it was. The crop was a good one, and was in due time thrashed out, when *nothing could exceed the beauty of the sample*. Just at that time the agricultural

society of the district announced a premium for the best sample of five tons of seed wheat; I became a competitor with the produce of the derided seed, and obtained the *first premium*. This is a fact well known in the neighbourhood where it occurred. The five tons were eagerly bought up for seed by different parties, and in every instance that I could ascertain the following season, the produce of it had degenerated.

The year following I sowed a large field with potato oats. This field had been part of the holding of a tenant who had rented it for seven years, and who had resigned it in wretched bad order. It was scourged out with over-cropping, poor in the extreme from the same cause, (not naturally poor) and crowded with root and seed weeds. The first season it was summer fallowed, and a number of boys, girls, and women were employed during the entire summer and autumn in collecting and burning the weeds which appeared after each ploughing and barrowing. In November it was ridged up for the winter. The next spring it underwent a preparation for Swedish turnips, and every root weed appearing was carefully picked off. It received an excellent manuring with farm-yard dung, and the crop of Swedes was very fine. The half of the crop was drawn off for cattle, and the remaining half was eaten on the ground with sheep. Having determined to lay it down to pasture for some years, and potato oats being then in great demand in the district, it was, the following spring, sown with that grain, drilled at nine inches, and grass seeds. The seed oats used on the occasion weighed 41lbs. per bushel. The crop was a splendid one, the produce weighing 48lbs. per bushel. It was shown for a premium offered by the society before-mentioned for the best seed oats, and the first or highest one was awarded to it. The article was greatly admired, and was all sold for seed, but in no instance that I could afterwards discover was the produce equal in quality to the parent; indeed in some cases the produce was so inferior that complaints were made by the parties who purchased it, hinting that they had been imposed upon, that the seed could not have been genuine potato oats, &c.; and various other causes, but never the right one, were assigned for the deficiency.

The same result occurred in the case of a field of barley, after turnips, which had been fed off by sheep. An article two or three removes from the best was used as seed; the produce was first-rate, and would also have obtained a premium had the grain not been very much discoloured by the prevalence of wet weather during harvest. Just about this time, I read in a Fifehire newspaper the account of a farmer's practice there, who was famed for growing good "seed barley" for sale. It was stated as a remarkable fact that the seed used by himself for raising the superior article he was famed for, was invariably of a *low* quality.

Public opinion has hitherto been against using any but the finest samples of grain for seed, judging that the finer the seed is, the better is the produce likely to be, and that, as vegetables incline to degenerate, the best plan is to sow the best seed of them which can be got, and thus avoiding degeneracy, and aiming at perfection. This would be all very well if the principle were a correct one, which it evidently is not; if it were, we should by this time have had wheat as large as beans, and as heavy. Grain of the weights I have mentioned, or approaching them, is about the limit

fixed by our climate for their attainment, and if we sow them with a view of raising a better or even as good, we shall find to our mortification, that instead of going forward we have been going backward. Change of soil and situation have no doubt an invigorating influence on plants subjected to them, but no change of soil or situation can add improvement to a production which has already attained perfection.

If "Nature is uniform in all her operations," and if we may judge of the whole of her great plan by a part of it, we have abundant evidence of the truth and correctness of the foregoing theory, in the habits of the cultivated potato. All practical men know that a potato tuber grown on good land, perfectly ripened there, mealy when boiled—a potato in fact as perfected as our climate, soil, and cultivation will permit, is the worst possible one for seed, because it produces a weakly, languid, unhealthy, curled plant, with a greatly diminished and greatly degenerated progeny; whereas, a watery, unripened, bad-to-eat potato is the best for seed, such being well known to produce a strong, healthy, vigorous plant, with abundance at the root.

It is pretty clear that, as yet, vegetable physiology is but very imperfectly understood amongst us, and those who have been attentive observers will be led to conclude that when vegetables, animals, or even the mental powers of man, attain an extraordinary degree of perfection, degeneracy in those particulars in which they have been superior seems invariably to await their offspring.

I am, Sir, your obedient servant,

P. C.

TO THE EDITOR OF THE FARMER'S MAGAZINE.

SIR,—Would it not trespass too much upon the pages of your valuable journal, I shall feel indebted by your publishing the annexed account of failure in a crop of Swedish turnips; thinking probably some of your numerous correspondents may be enabled to inform me of the cause and its preventive. The soil is a deep clayey loam (without stone) and was reduced to a fine tilth; then dressed with 16 cart loads (two-horse) of farm manure, ploughed in and drilled the same day with Swedish turnip seed, at the rate of 4lbs. per acre, and 20 bushels of cinder ashes per acre, on the flat 18 inches, from drill to drill; the seed vegetated quickly, and the braird exhibited a good and healthy appearance when first hoed. In walking over the field about ten days after hoeing, my attention was arrested by some of the plants exhibiting a sickly and blueish appearance; upon a strict scrutiny, I discovered a great many of the plants decaying at the root, and exhibiting what is sometimes termed fingers and toes. Full one-half of the plants are now dead. I found a small white grub, and in some three or four about the length of a barley corn in the tap-root. I suffered a similar loss last year on the same kind of soil. The crop previously was a very great crop of wheat, and the land generally produces great crops of wheat and beans. Any information on the above will be esteemed a favour. I have the honour to subscribe myself,

Yours most obediently, T. D.

Godney, South Lincolnshire, Aug. 8.

ON CLAY.

Clay, (clay, *kley* Dutch, from *kleben*, German; *kley*, Teutonic; *kleg*, *cloeg*, Saxon; *glie*, Latin; *glaise*, French, from *γλια*, Greek, gluten; or from *γλινος*, Greek, *viscosus*, *glutinosus*, a clammy earth, tenacious and capable of being moulded,) is a mixture of several earths in common language, often containing a larger portion of silica than of alumina, from which the name is properly derived. It has been long known by the name of "argil" from "Argilla," Latin, from *αργιλλος* or *αργος*, Greek, white, as being a white earth, and *συνπτηρια* from *συνωω*, Greek, adstringo, et *Buglum* et *inula*, *gustu dulcis* decisi quæ gustantur, from "Halas" or alum, from the roots of the herb Comfrey yielding a sweet and astrigent liquid, sitim ledans; and latterly "alumen," from "*αλμη*" Greek, marl, or a salsugo, or salt at the bottom of salt pits; or from "lumine," from *αλειφως* Greek, ungo et illino, quia lumen coloribus tingendis præstat, being a sudor lapidis, a spuma dehis cens et coagulatus, and was formerly divided into "alum liquidum" or rock alum, and "alum scissile" or stone alum, and "alum catinum," or the kind used in making glasses. In our modern chemical nomenclature, the name "alumina" or rather "alumine" has been adopted from the French, and "alumina" is now defined to be the oxyde of "aluminum," one of the newly discovered metals, which unites with only one proportion of oxygen, and forms the well known base called "alumina," which contains 100 parts of aluminum and 8 of oxygen. It is the essential constituent of clay, and forms the basis of alum, enters into the composition of many minerals, is found pure in the corundum genus, and especially in the sapphire, and is a very abundant earth, entering into most soils and solid strata of the globe, the different colours arising from the various portions of the metallic oxyde. It has been called "argil" from forming a part of clays and giving them the plastic properties, and the ductility and tenacity in baking and working; but latterly "alumine," from being obtained in the greatest purity from alum. This last substance is a salt well known many centuries ago and used in dyeing, is a solid salt and sub-acid, sp. gr. 1.7 to 1.8, and occurs as an efflorescence on the aluminous minerals in Britain and in various parts of Europe; colour yellowish and greyish white, a farinaceous and stalactite efflorescence, sometimes pearly, glistening and vitreous; concretions curved and parallel, fracture conchoidal, dissolves in 16 to 20 times its weight of water, but in equal bulk of boiling water, absorbs 2½ times its weight of water, melts by water and heat, and is converted into a white spongy mass; is a triple salt, the sulphate of alumina and potash, and contains:—

Alumina	15.25	or	10.8
Potash	0.24	„	10.1
Oxyde of iron	7.50	„	00.0
Sulphuric acid and water	77.00	acid	33.7
		water	45.4

100.00 100.0

Rock alum from Monte Tofia in Italy contains:

Sulphuric acid	27.05
Alumina	31.80
Potash	5.79
Silica	28.40
Water and loss	3.72

Sp. gr. 2.4 to 2.6.

By other experiments alum was found to contain:—

Sulphate of alumina	49
Do. of potass	7
Do. water	44
	100

and,

Sulphuric acid	38
Alumine	18
Water of crystallization	44
	100

Alum heated in its water of crystallization, swells and enlarges much, and produces burnt alum, a light, porous, dry, mass which in a solution turns vegetable blues to red. Sp. gr. 1.7.

Rock alum of Monte Tofia contains:—

Sulphur	43
Clay	35
Silica	22
	100

and,

Sulphur	40
Clay	50
Fixed vegetable alkali potassa and iron	10
	100

The sulphuric acid is formed by the preparation by the sulphur, and potassa is added to make the salt.

By another analysis:—

Alumine	43.92
Sulphuric acid	25.00
Potash	3.08
Water	4.00
Silex	24.00
	100.00

Found in masses and veins and running through argillaceous rocks, and in secondary formations, and prepared by roasting and lixiviation.

The alum slate of Whitby occurs near coal, and differs little from bituminous shale impregnated with pyrites.

Rock alum belongs to the genus "Haloide" as being a stratified body; the former analysis belongs to the order "Salts."

Alum is used in giving a white colour to bread, and in preserving animal substances from putrefaction, in making leather and paper, and as a mordant in dyeing.

Alumina is a fine white bland powder, adhering strongly to the tongue, but excites neither taste nor smell. It is insoluble in water and alcohol, but has a considerable affinity for water, increasing in weight about 15 per cent. by absorbing moisture and retains it with great obstinacy; contracts by heat and dissolves readily in caustic potash or soda after ignition, dissolves slowly in sulphuric and muriatic acid, assisted by heat, and may be fused by a violent heat into a white semi-transparent enamel: sp. gr. 4.200 or 2.00 by others. It unites readily by fusion with other earths, particularly with silica, and much of its utility in the arts arises from this power of union. It unites by fusion with some of the metallic oxydes but not with metals, and by an easy dissolution in acid forms many salts more or less soluble and susceptible of crystallization, and others are insoluble and require an excess of acid. Alumina has a strong affinity for lime if it

exceeds the lime in quantity; if the lime be in excess, fusion does not take place. It does not combine with oxygen, nor with any of the simple combustibles, and azote has no action on it. It has a strong attraction for colouring matter, and hence the use in dyeing and in calico printing, and the union with silica and lime forms the basis of all pottery and porcelain, from the coarsest brick to the finest china. Alumine forms a paste with water and hardens with the action of fire, and loses the first property by acquiring the second; to regain it, it must be dissolved in an acid and precipitated; it is made hard enough to give fire by steel, and to cut glass with a diamond.

In the Natural History arrangement, the clay and lithomarge families are placed in the genus "Felspar," from their affinity with the preceding genera, as they have no regular form or cleavage, and are not connected with any of the mineral species. The clay family contains several divisions, of which common clay and potter's clay only require notice here. The former occurs in great beds in the alluvial districts, and includes the loam of which mud houses are built, and it is thought that the walls of Babylon, and the ancient city of Damascus, were built with bricks made of this substance. It occurs in many colours, as grey, brown, yellow, with spots of all the colours intermixed; massive, fracture coarse and small grained, soils slightly, frangible, sectile, friable and soft, adheres slightly to the tongue, and feels rough, greasy, or meagre. Earthy and slaty potter's clay occurs in beds in the alluvial districts; colour white and grey; massive, soft, and friable, adheres more strongly to the tongue than loam, feels greasy and becomes plastic in water; it is infusible, and contains:—

Silica	61
Alumina	27
Oxide of iron	1
Water	11

100

Its uses are well known in all pottery wares, in bricks, crucibles, and tobacco pipes, and it is also used in manuring land.

Clay is found in vast beds of alluvial or diluvial deposit in the tertiary formation, of which the chalk, or the most recent formation of lime, forms the basis. The omission of the term "diluvial" reckons every deposit to be "alluvial," that is more recent than the chalk, and so far simplifies the arrangement. Clay is much mixed with other bodies, principally with silica, and the different colours are owing to the presence of oxide of iron in different states and combinations. The prevailing colour of clay is brown or reddish brown, white, grey, yellow, sometimes blue, sandy and gravelly, often solid, more or less unctuous and soft to the touch; often dry and friable, and breaking into small lumps, from containing more silex and losing its plasticity, and there is perhaps no substance that enters so largely into the composition of bodies that is found in a greater diversity of composition. It enters into all good lands, slates, and all argillaceous formations; in fertile soils, argil forms 9 to 15 per cent. sp. gr. 1.58, in barren soils as much as 20 to 40 per cent. sp. gr. 2.20; the absence of it forms a soil too dry and porous, a proper quantity constitutes our best clays and clayey loams, and a superabundance of it forms soils too wet and cold for vegetable life in a moist state, and hardening and contracting by heat into a condition very hurtful to the growth of plants. The uses of

clay in pottery and brick-making are well known; for the latter purpose, the best proportions are, silex 86, alumina 14. The red colour of bricks and tiles is owing to the alteration of the oxide of iron during the process of burning, the iron being further oxidised by the decomposition of the water applied to the clay in kneading. Much oxide has a tendency to vitrify the bricks if any lime be present, and the proportions of silex and alumina also mechanically affect the character of the articles in making them too dry and rifted, and not sufficiently ductile. The quality and appearance are thus affected both chemically and mechanically.

Clays have been further divided into calcareous, meagre, and unctuous. The first effervesces with acids, is more friable than some others, owing to the presence of lime; is used in brick-making, and, by judicious burning, may be made semi-vitreous and very durable. Meagre clay is gritty, rough and coarsely granular, and is used for inferior articles, as bricks and tiles. Unctuous clay contains more alumine; if it contains little oxide of iron, it burns white and is used for fine ware; if more oxide be present, it becomes more fusible, and can only make coarser pottery. The purest clay contains upwards of 60 per cent. of sand, and is always mixed with mineral, animal, and vegetable substances.

The quality possessed by clay of imbibing and retaining moisture as much as two-and-a-half times its bulk without dropping, and rendering land more solid and consistent, and the very faulty composition of sands and all light lands in that respect, long ago led to the idea of improving the one soil by mixing it with quantities of the other, and to confer the quality that is wanting in the one by applications of the substances which have that quality in excess. Very great improvements have been made in many places by this application; but peculiar circumstances have occurred in rendering the application effectual. The light lands of Norfolk have been greatly and permanently improved by raising the clayey stratum below the soil and mixing it gradually with the land; but the clay is of a calcareous nature, and consequently partakes of the qualities of marl, and possesses a friability to fall down and crumble, and incorporate with the soil. In such cases, the improvement is obvious; but the great diversities found in the quality of clays, the convenience of getting it, the quantity required to effect any valuable improvement, and the difficulty of reducing to particles the clammy or indurated texture of the substance, operate in the different relative bearings on the expediency of the application. Ferruginous clays and those of a white sandy nature, and the gravelly sorts and many others, are positively pernicious; and it is only when the substance has attained a form of solid consistence more or less unctuous and friable, and pretty clear of mixtures, that the use of clay can be judiciously recommended. From 60 to 160 loads have been laid on an acre with much success; while in other cases, the return has been wholly inadequate, arising no doubt from the qualities of the contrasted substances, and also something on the mode of application, and very probably on the future culture. The best mode of applying it would be in laying it on sandy lands in autumn or in the early winter, when the action of the weather will assist to reduce the stiff substances, and afford an opportunity of being mixed with the soil by the fallowing of the land for green crops. Without a

very liberal quantity and attention to the application, little or no benefit will be derived.

When beds of clay are found of a solid consistence, and free from mixtures of sands and gravels, very good composts may be made by mixing it with lime in large quantities, that the latter may be able to penetrate and crumble the cohesive mass, dis sever the particles, and form a kind of artificial marl which is a very valuable manure either on arable or grass lands, particularly on the latter. A very general mistake lies in allowing much too small a quantity of lime, which produces no effect by being incorporated with the clayey substances, and in most cases the tenacious mass is carried out and laid on the land nearly in the same state as when laid in the heap, reduced a little by turning, and whitened externally by the lime; but it has not been subjected to the mutual action of affinity of particle, the essential aim and purpose in the preparation and application of all substances that are used as manures. There are few farms that do not afford materials for composts, which are in most cases wholly neglected, while a great desire is evinced for extraneous sources of a very uncertain and even feeble operation. It must always excite our wonder that the fullest advantage is not used of every natural supply in conjunction with, and even previous to the application of foreign assistance.

It would appear that the burning of clay for manure has been known for upwards of a century—but we are left in doubt if the substances used where clays taken wholly from the subsoil, or rather surface soil from fences and head-lands, and consequently containing a greater or less quantity of vegetable matter. In the latter case, the operation and effects of it are the same as in the process of paring and burning. The following observations will be confined to clays dug from the subsoil, and reduced by calcination as nearly as possible to a state of ashes. For effecting this purpose, large kilns have been erected and built with bricks, with a fire place underneath provided with flues to convey the heat regularly over the whole mass. These erections are expensive and stationary, and consequently incur an expense in carriage, when the places of procuring the material and of application are distant. They may be varied in size and form to suit the expected use of them; the cost of erection is usually objected, but when once expended, there is an end of it, and no repetition is made or called for. The simplest mode is to erect kilns of turfs and sods on the head-lands of the fields where the ashes are to be applied, and to mix the foundation of the heap with wood, straw, culms, or similar combustibles, and lay on clay as required and to keep the mass in a smothering state by a close surface. The main object to be attained in burning clay is to prevent charring, or the reducing it to brick-like substances by too strong heat; a flame must not be allowed, and the heap must be kept closely shut up from exposure. In order to produce a smothering heat, the air must be excluded as much as possible, and the smoke kept in; the clay should be applied in a moist state, which the heat gradually banishes, and steams the clay, without a tendency to harden it, which would follow if it was used dry. Some experience and attention is required in managing the burning process; but it may be conducted very economically when once a little understood. The ashes obtained by this mode will contain

vegetable matter from the turfs that are used, and from the outside walls and in laying the foundation; and it also supposes the clay to be dug from the field, which, if the quantity be great, will cause excavations that may be inconvenient, and where the country is well enclosed and the land valuable, the sacrifice of surface might be grudged, as the unsightly pits cannot be repaired. If the system be reduced to extensive practice, it is evident that one kiln or more must be built convenient for getting the material, and of a size to yield a quantity worth the labour and expense. The most approved plan is an oblong shape, built with bricks in the manner of a gridiron floor, with flues longitudinally and transversely, and a chimney at the end opposite the furnace. The flues are arched over to sustain the weight of the clay—the size may be 20 feet in length, 12 feet in breadth, and four feet in height, which will burn about 200 loads of clay, and cost about 10*l.* in erection. The expense of burning will vary with the cost of fuel; with wood, it has been stated at 2*d.*, and the whole cost with all labour included at 10*d.* per cart load; in other cases, from 4*d.* to 6*d.* exclusive of the cartage. After the quantity laid on the kiln is calcined, the fire is extinguished, and the ashes will require time to cool before application, if the crop of tender plants come into immediate contact with them.

Clay, or rather the surface soil of banks of head-lands in a cloddy state has been very advantageously burned, and the success is obvious where fuel, such as bushes, weeds, straw, wood, or gorse can be found, and where the land is in a rough state to afford the materials to be burned. All rough materials on newly improved and uncultivated lands, that would incommode the culture or require an inconvenient time to decompose and incorporate with the soil, may be very speedily and beneficially reduced by burning; but the propriety of going further and of interfering with the vegetable matter that should remain for easy and gradual decomposition in the soil by the operations of future cultivation, has been much doubted by many eminent practical and scientific men. The burning of the cloddy surface of land under aration, has also been practised, and it would appear with success in certain places, where materials are abundant; and while the benefits conferred on and by the effects of fire are undoubted, the want of fuel to effect the process in all enclosed and cultivated countries, will much check the adoption of the method, for if straw be used, the value of it may soon amount to a considerable sum, and may be supposed capable of a better application elsewhere. If small heaps of clods are raked and laid on a small quantity of straw or culm, the blaze will soon be extinguished, and the heat evaporated, from the wide exposure of the surface. If larger heaps be made, much fuel will be required, and very considerable expense in forming, and afterwards spreading out the heaps, and also much care and attention in smothering the fire, and preventing the outburst of the flame, and reducing the earth by a violent heat to a calcined substance, equally unfit for the purposes of vegetation, and incapable of mixing and of absorption. In closely improved countries fuel cannot be got, coals may not be applicable, wood is as dear in many places, straw is equally valuable, and gorse, hedge-cuttings, and prunings of trees are only obtained at certain periods of time, and in particular situations; but in localities that are suitable, and

in circumstances that admit the application, the process may be advantageously employed.

The most economical, and by far the simplest and most generally applicable mode of reducing the cloddy and clayey surface of land, is to lay narrow mounds of alternate layers of the clayey surface and hot lime, and to ignite it by exposure to the air, or by an application of water. A heap of seven yards in length, four in width, and three in height, mixed with seventy-two bushels of hot lime, has been recommended to be reduced to ashes, or nearly so, when fresh clay may be applied so long as sufficient heat remains. The heat exhaled from the lime will produce a smothering effect on the clay not easily obtained in the open air with a large or small quantity of flaming combustibles. In the former case, there is danger of calcination and uselessness, and in the latter of imperfect burning, and of the fire being extinguished from exposure, and the surrounding contact of air. The lime can be got at any time, and the process can go on during summer in wet or dry weather; the means are more at the command of the farmer, and the work can be effected more promptly on that account than when it depends on so many contingencies often altogether beyond control. The expense of burning in heaps has been stated at from 1s. to 1s. 6d. per load, and of clod burning at 12s. to 15s. an acre, but very little dependence can be placed on such statements, or on the loads that are said to be applied, or on the quantity of ashes obtained from a quantity of land, as circumstances cause a variation in every case. The quantity of ashes should be sufficient to cover the land when spread; if less, the application may be worth little, and a greater quantity can be got at a less proportionate expense than a smaller. The mode of burning by lime cannot be too much pressed on the attention of the farmer as a simple, effectual, and at all times available process, and the ultimate products are a mixture of finely reduced and pulverised substances to be blended and incorporated with the soil, on which acquisition so very much of the fertility of the earth depends.

About thirty years ago, the accounts of the wonderful effects of burnt clay as a manure made a great noise in the agricultural world, and it was assured that the substance would soon supersede the use of putrescent matters or any other manures, and that it could not fail to introduce a new era into our practice, and with results seemingly but little short of Mosaic miracles. It was applied at the rate of 30, 40, and 60 cart loads per acre, and produced a crop of 40 tons of turnips, and the success was so decisive over rotten dung of the farm-yards as to lead to the contempt and neglect of that substance, though it were offered free of cost, and with only a mile of carriage. The cost was about 6d. per load exclusive of carriage. Twenty-five loads of clay ashes have beat fifteen tons of dung; on corn crops, and on seed as a top-dressing, the results were very striking, and for green crops 20 to 30 cubic yards have been found equal to 8 or 12 tons of putrescent manure. In experiments between 400 bushels of clay ashes, 50 of soot, 100 of wood ashes, and no dressing, the superiority was trifling in favour of the former compared with wood ashes, one-half above soot, and nearly double the produce of no dressing, in the respective crops of swedes, kohlrabi, potatoes, and barley. The same superiority was observed in clay ashes over composts of clay, lime, and earth, and was even reported to show the unexpected quality of possessing more moisture than farm-yard

dung, and producing, in consequence of that property, a better crop of turnips. But these results were completely eclipsed by one individual case, which laid aside both farm-yard dung and the ploughing of the land, and substituted scarifying the surface, and the application of burnt clay. The advantages of the mode have been fully detailed, and though it may never be reducible to practice in the full extent, it contains abundant matter for reflection, and has not met with the attention that is due. Clay is composed of silica and alumina, oxyde of iron, some little inflammable matter, and probably some other substances in a very minute ratio. That these oxydes, which contain in themselves none of the elements of vegetation, after being again subjected to the action of fire, and partially oxidized, and laid on land, either broadcast or in a drill, and well cooled before application—should be more moist and nutritious to any crops, either in dry or wet weather, than a mixture of animal and vegetable matters prepared with similar care, bears an air of incredibility that is fully confirmed by the most rigid observation of the most extensive and enlightened experience. No one denies that stimulants are known that will produce great efforts in the animal body, but we know also that other substantial and nutritious substances are required to support that exertion, and that without them a repetition of the stimulants produces debility and ruin. Without attempting to establish an exactly similar analogy in the case of the earth being stimulated to produce a large crop of plants, as we have not the same means of ascertaining the causes that produce the effects, experience, our only true guide in such matters, fully warrants an inference very nearly allied to it; for the idea of supporting a fertility created by saline or any similar substances, will not remain long in the mind of any experienced cultivator. A person is very naturally surprised to think whence have been derived the astonishing results always published of the first application, not only of burnt clay, but of various other substances that have been applied as manures; they are seldom realized, and never found when fully brought to the fair and unbiassed test of experience. A sanguine and prejudiced mind often directs the process, neglects the proper observations, draws inferences from false premises, and a jaundiced eye frequently sees the results drawn up, and the statements which cannot be long repeated, even by the parties themselves. Without impugning the correctness or veracity of such statements in the particular cases of occurrence, much caution is always to be used in putting forth too much generalized opinions on such subjects. In the case of burnt clay, physical circumstances that always interfere and direct on such occasions, and the sober maxims of prudence, have now confined the use of it to the natural limits of convenience in getting the materials, and of the probable effect in relation to the cost. Waste grounds will afford a pit where the clay may be dug, and a permanent kiln erected near it; but on good lands, the waste and disfiguration of the surface will be grudged, for clay does not produce like plants by the application to land, substances similar to itself to repair the waste. Where a pit is convenient, the clay of good quality, and fuel not too dear, the method may be used discreetly, according to the above circumstances, and more especially by the effects it is seen to produce from being used on the fair and tangible grounds of comparative application.

Burnt clay possesses none of the caustic solvent effects of calcined lime. The water has been banished by the application of fire, and the earths have been divided and reduced to minute particles, and invested with an unknown property which bodies acquire that have undergone the process of torrefaction. The substance must be as completely powdered as possible, and may be applied on arable lands for any crop, either green or culmiferous. It can only act mechanically as an alternative in rendering the soil more friable, as the particles seem to have lost the power of coherence, and lie compact for a time without uniting; and in order to effect any valuable and permanent benefit, the quantity should not be less than from 30 to 60 loads, varying from 600 to 1,000 bushels.

July 18, 1840.

J. D.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

At a Council held on Wednesday, the 22d July, in Cavendish-square, present, Philip Pusey, Esq., M.P. (President), in the chair; Marquis of Downshire; Earl of Euston; David Barclay, Esq.; Thos. Raymond Barker, Esq.; Colonel Challoner; J. W. Childers, Esq., M.P.; John Evelyn Denison, Esq.; John Kinder, Esq.; Sir Francis Lawley, Bart.; Sir Robert Price, Bart., M.P.; Rev. W. L. Rham; Edward Ayshford Sanford, Esq., M.P.; William Shaw, Esq.

The Secretary was directed to issue a notice to each Member of the Council, that the subject of the new prizes to be offered by the Society would be taken into consideration at the next meeting.

It was resolved, that a Deputation should be formed to attend the Meeting of the Highland Society at Aberdeen, in October next.

It was decided that the Society's Annual County Meeting at Liverpool, next year, should be held in the week after Liverpool Races, and that the principal day of the show should take place on a Thursday instead of Wednesday, as at Oxford and Cambridge.

The Committees of the Society having become extinct at the Annual Meeting, the Council proceeded, agreeably with the by-laws, to revive the Finance, Journal, Geological, and Veterinary Committees; Lord Braybrooke being added to the Finance and Journal Committees, and Sir Thomas Acland to the Geological Committee.

The Duke of Richmond communicated a paper from Mr. Bulmer, on the Cultivation of a Berwickshire Farm. Papers were also received from Mr. Alexander, Mr. Cresskill, and Mr. Thomas Wilson. Other communications were also laid before the Council from Professor Henslow, Mr. Porter, Mr. Manning, and Mr. Starkey.

At a Council held on Wednesday, July 29, present, P. Pusey, Esq., M.P. (in the chair), Earl Ducie, Earl of Euston, David Barclay, Esq., Thos. Raymond Barker, Esq., Thos. William Bramston, M.P., French Burke, Esq., Sir Charles Burrell, Bart., M.P., Colonel Challoner, John Ellman, Esq., Humphrey Gibbs, Esq., Stephen Grantham, Esq., Henry Handley, Esq., M.P., William Fisher Hobbs, Esq., Samuel Jonas, Esq., George Kimberley, Esq., Thos. Thornhill Morland, Esq., William Shaw, Esq., Thos. Weall, Esq., William Youatt, Esq.

The President read a letter addressed to him by his Grace the Duke of Richmond, thanking the Council, as his colleagues, for their vote of thanks for his conduct in the chair during the year of his Grace's Presidency, assuring them that he was most sensible of their kindness, and that it would give him at all times the greatest satisfaction to co-operate with them in carrying out

the measures which have been so favourably commended.

A committee was appointed, consisting of Colonel Le Couteur, Professor Henslow, and John Morton, Esq., to consider the best mode of forming a collection of samples of wheat.

Mr. Raymond Barker reported that Colonel Challoner, on the motion of David Barclay, Esq., had been duly elected Chairman of the Finance Committee for the ensuing session.

The council then proceeded to the consideration of the question of the new prizes to be offered for improving the breed of cattle, and the new subjects for prize essays.

Mr. W. D. Field, of Ulceby Grange, in Lincolnshire, presented the model of a shed for the equal distribution of linseed cake, or other food, to store cattle. Mr. Gibbs presented a specimen of the wool from lambs which were the offspring of the Doombaram and South-down ewes; and Mr. Cole, the editor of the "Yankee Farmer" (an American agricultural paper, published at Boston), presented several numbers of that journal.

A letter was read from Mr. Wyon, of the Mint, announcing that the dies for the society's medal were on the point of being completed.

The Hon. Bellow Nugent, of Ettingham House, Leamington, and John Nott, Esq., of Bydown House, near Barnstaple, were elected Governors; and the following gentlemen Members, of the Society:—

Honourable Colonel Greville Howard.
Sir Baldwin Leighton, Bart.
George Edward Blouchamp, The Priory, near Reading

Lord Sidney, Cleveland-row
J. M. Cripps, Newington, Lewes, Sussex
Richard Willis, Wanstead Park, Van Diemen's Land
Arthur Willis, jun., Wanstead, Essex
John Dicken, Waters Upton, Wellington, Salop
W. P. Hayward, Wilsford, Devises
W. Hodson, West Bletchington, Brighton
E. Majoribanks, 77, Harley-street, London
Rev. Basil Berridge, Alkerkirk, Boston, Lincolnshire
J. S. D. Selby, Chinnel Park, Berwick
William Bird, Bishop's Stortford.
William Cole, Oakington
William Bate, Warrington, Peterborough
John Postle, Smallburgh, Worstead, Norfolk
William Postle, Smallburgh, Worstead, Norfolk
Sir John Palmer
George Robert Gausson, Brookman's Park, Hatfield, Herts

Samuel Shrobb, St. Alban's, Herts
James Spirling, Halstead, Essex
Richard Knight, Duntun Hall, Brentwood, Essex
Sir Thomas Birch, Bart.
Thomas Buller, Joychurch, New Romney, Kent
William Carter, Boughton, Faversham
Henry Hilton, Solo-street, House, Selling
Nathaniel Rix, Ridge, near Barnet
Rev. Richard Fardell, Wisbeach, Cambridgeshire
A. S. Elliott, Hartford, Huntingdon
John Stracey, Rackheath Hall, Norwich
James Sandle, Great Ockendon, Essex
W. P. Standley, Peterborough
John Perkins, Gedney Hill
John Williams, Bedford
Rt. Ridge Ellis, Yelding, Kent
John Whitehead, West Barming, Kent
James Ramsay Warde, Yalding, Kent
F. C. Marsom, Cumberland Terrace, Regent's Park
John Thomas Mott, Bickling Lodge, Aylesbury
William Rutson, Newby Wisk, Northallerton
W. Baldwin, Hewell, Bromsgrove
J. Morris, Walcote, Bishop's Castle
Edward Umbers, Weston Hall, Leamington
John Whittington, Walton, Welsbourne, Warwick
Hon. Elliot Yorke, 4, Norfolk-street, Park-lane
Thomas Yard, Whiston, Devon
Philip Francis, Moore Crediton, Devon

Hon. B. Nugent, Effingham House, Royal, Leamington, Warwick
 Charles, Leslie, Glaslough, Ireland
 Dr. Harrel
 Robert Allin, Bailingdon, Sudbury, Suffolk
 Lewis Bucke, Esq., M.P., Moreton, Bideford, Devon
 Captain Lempriere, Alton, Hampshire
 John Reynolds, Wisbeach
 Rev. S. C. Smith, Denver Rectory, Downham
 Wm. Edw. Dewing, Leiston Hall, Suffolk
 Rev. W. Skinner, Rushton, Herts
 John Paris, Farnham, Essex
 Wm. Mott, Wall, Lichfield
 James Bailey, Nyncehead, Wellington, Somerset
 George Jebb, Brynkenatt, Chick, North Wales
 Captain Randolph, R.N., Wrotham, Kent
 Wm. Charles Smith, Shortgrove, Essex
 Wm. Downes, Dedham, Essex
 P. Pryse, Gwyddard, Aberystwith
 D. Blyth, Great Massingham Rougham
 Edmund Farrer, Spoile Swaffham
 Henry Brandreth, Oxford and Cambridge Chronicle
 and Houghton House, Dunstable
 Charles Boyer, Whittlesea, Cambridgeshire
 Charles Etheridge, Starston, Norfolk
 James Scott, Bromley, Kent
 Thomas Mortlock, Coombe Grove, Cambridge
 Colonel Best, Boxley, Stratham
 John Best
 T. L. Allen, Trinity College, Cambridge
 John Courtier, Morton Hampstead, Dover
 Wm. Chambers, Derby
 John Bromley, Derby
 Henry Mortlock, Caxton
 W. Ashling, Whittlesea
 Dr. Hopkinton, Stamford
 Thomas French, Eye, Suffolk
 John H. Tuck, Blofield, Norfolk
 J. Marshall, Hitchen, Herts.
 T. Elsom, Whittlesea, Cambridgeshire
 Henry Hayes, Whittlesea, Cambridgeshire
 John Child, Merton Mills, Surrey
 J. J. Tuck, Wortham, Suffolk
 J. G. Hart, Stowmarket, Suffolk
 John Brickwell, Leckhamstead, Buckingham
 R. Faulkes, Beckingham, Newark
 Sloane Stanley, jun.
 Nathaniel Forte, Trinity College, Cambridge
 Reginald Bryan, Trinity College, Cambridge
 Mark Cooper, Great Oakley, Essex
 George Bull, Great Oakley, Essex
 Rev. A. Austin, Compton, Wilts.
 W. Smith, Barton Mere, Suffolk
 George Smith, Barton Mere, Suffolk
 P. B. Smith, Great Clacton, Essex
 T. Croydon, Drayton, Penkridge
 R. Dudding, Ponton, Wragby
 G. Botham, Wexham Court, Bucks.
 J. Aldridge, Cippenham Burnham, Bucks.
 C. S. Cautrell, Manor Farm
 H. Cautrell, Baylip Stoke, Bucks.
 John Thistlewood, Lornecroft, Louth.

Peed, Anthony, Cambridge
 Brettell, John, Northampton
 Fuller, T., Dinemow
 Bird, J., Bishops Stortford
 Allenborough, Rt., Braybrooke, Market Harborough
 Golpin, J., Dorchester, Dorset
 Oliver, F., Dorchester, Dorset
 Warne, J., Upway, Weymouth
 Baker, Samuel, Hawkwell Hall, Rockford
 Francis, Benjamin, High House, Lechams, Norfolk
 Jackson, Thomas, Hill Redware, Staffordshire
 Thacker, Charles, Elford, Staffordshire
 Baulnois, Wm., 12, Abbey Road, St. John's Wood
 Bland, Clement, Frith House, Stansford
 Pinkus, Henry, Slaughter's Hotel, London.
 Bennett, Philip, Roagham Old Hall, Bury St. Edmunds
 Campton, Rev. Job, Overstone Rectory, Northampton
 Williams, Thos. Bryn, Beaumaris, Anglesea
 Bolden, J., Hynning, Lancaster
 Jones, A. G., Gloucester
 Garth, Rev. Richard, Farnham, Surrey
 Brooke, John, Great Walsingham, Norfolk
 Watson, G., Fakenham, Norfolk
 Sepping, E., Swaffham, Norfolk
 Abbott, Stephen, Castleacre, Swaffham, Norfolk
 Stappilton, Rev. Martin, Barlborough Rectory, Chesterfield, Derbyshire
 Maitland, Rev. J. G., Surrey Villa, Lambeth, Surrey
 Hunt, Rev. Geo., Barmingham Rectory, Botesdale, Suffolk
 Fitzroy, Capt. Hugh (Grenadier Guards), 3, Chesham Place, Belgrave Square.
 Callis, John, Mears Ashber, Northampton
 Hagger, Thos., Northampton
 Ringer, John, West Harling, near East Harling, Norfolk
 Brokenbrow, H. P., Beenham, Reading
 Garrod, Robert, Ipswich
 Stone, Geo., Fawley Farm, Wantage
 Carne, Rev. T. C., Breckenhurst, Southwell, Notts
 Milward, R., Hazgreave Park, Southwell
 Milward, Thos., Thengarton Hill, Southwell
 Ward, G. A., Downham Market, Norfolk
 Woolf, Jos., Haslington Hall, Nantwich
 Kellow, John, Woodhouse, Andover, Hants
 Hayward, Wm., Wilsford, Devizes, Wilts
 Bruges, Wm., Haxton, Amesbury, Wilts
 May, C. H., Sneyd Farm, Burslem, Staffordshire
 Stapleton, Valentine, Lincolnshire
 Bazalgette, S., King's Bridge, Swallowfield, Reading
 Lys, Stephen, Harlow, Essex
 Thompson, J., Ilford, Essex
 Stokes, Jonathan, Stamford Rivers, Romford
 Henry Handley, Esq., M.P., John Evelyn Denison, Esq., and Colonel Le Conteur, were nominated Members of the Deputation to the Great Meeting of the Highland Society.
 The name of C. E. Lefroy, Esq., was added to the list of Members of the Journal Committee.

SPECIMENS OF WHEAT.

It was resolved, that as Professor Henslow, Colonel Le Conteur, and Mr. Morton, had undertaken to superintend the formation of a collection of wheats for the Museum, members should be requested to preserve specimens of the ordinary wheats of their neighbourhood at the present harvest: five straws of the full length with the ear to be sufficient for each wheat; one being the best sample, and the other four average samples; members being requested to give the local name of each wheat, and any other local name with which they may be acquainted; and forward the specimens to the Society's rooms.

Captain Stanley Carr, of Trischenbeck, in the Duchy of Lauenburg, an English gentleman, who is successfully introducing the improvements of English Agriculture into Germany, and transmitting to this country those of the Continent, author of the "Prize Essay on Rural Economy Abroad," and of another paper in the Journal, on the "Rural Economy of Schleswig, Holstein and

At a council held on Wednesday, Aug. 5, present, Philip Pusey, Esq., M.P., President (in the chair), Earl of Euston, Thomas Raymond Barker, Esq., French Burke, Esq., Colonel Challoner, Humphrey Gibbs, Esq., Henry Handley, Esq., M.P., John Kinder, Esq., Rev. W. L. Rham.—

Henry Brandreth, Esq., of the Oxford and Cambridge Club, London, and of Houghton House, Dunstable, was elected a Governor; and the following gentlemen Members of the Society:—

Belham, Robt., Stow Beeton, Norfolk
 Brown, John, Little Hallingbury, Sawbridgeworth
 Alexander, James, Doncaster
 Balls, W., Stapleford, Cambridge
 Brand, John, Berwick Hall, Whitecolne
 Hoste, Derick, Berwick House, Docking, Norfolk

Lauenburg," having presented to the society a valuable and interesting collection of agricultural models for its museum, was, on the motion of Mr. Handley, unanimously elected an honorary member.

Colonel Challoner read to the Council the Report of the Finance Committee, recommending for payment the various premiums and other claims on the society, on account of the Cambridge Meeting, and cheques for the respective amounts were ordered accordingly. Colonel Challoner, as Chairman of the Finance Committee, also presented to the Council a balance sheet of the receipts and expenditure of the Cambridge Meeting, from which it appeared that the expenses attending the meeting exceeded the receipts by upwards of 100*l*.

The Imperial Society of Agriculture of Moscow was proposed by the President, and unanimously placed on the list of corresponding societies.

The Council then proceeded to revise the proof-sheet of the new premiums to be offered by the society.

Communications were received from Mr. Dean, Mr. Hillyard, Mr. Connop, Mr. Cuthbert Johnson, Mr. Lance, and Mr. Oliver.

Mr. Jones presented a paper and specimens, on the subject of "the Brown Turnip Grub;" Mr. Deck, of Cambridge, transmitted to the society, on the part of Dr. Buckland, two beautiful geological models of the Isle of Wight, and two models intended to illustrate the principle of Artesian springs. Mr. Raymond Barker submitted a specimen of the clover plant, growing on a chalky soil on his estate in Oxfordshire, from the Indian seed presented to the council by Professor Royle. Mr. Pinkus presented his work and drawing on a new agrarian system: The following publications were also presented:—Colonel Le Couteur, a copy of his valuable work "on the Varieties, Properties, and Classification of Wheat;" Mr. Maul-everyer, two parts of the "French Agricultural Monitor;" Mr. Wallis, his work on "Dendrology;" Monsieur Haricart de Thury, his Report to the French Agricultural Society, "on the Draining and cultivation of Vallee de l'Authion;" Mr. Youatt, the last number of the "Veterinarian;" the *Mark Lane Express*, the *Bell's Weekly Messenger*, the *Farmer's Journal*, and the *Magnet*, were also presented by their respective editors.

The next annual country meeting of the Society being fixed for the Thursday after the week in which the Liverpool Races take place. Mr. Wetherby (of the Haymarket) has informed the Society (at the suggestion of his Grace the Duke of Richmond) of the exact time when the races take place, namely, that they commence on the second Tuesday or Wednesday in July, 1841.

The meetings of the Council were then adjourned to the first Wednesday in September.

The business year of the Royal Agricultural Society of England may now be said to have closed, and having been an almost constant attendant at the council during the last twelve months, we cannot permit this occasion to pass over without bearing our humble testimony to the zeal, assiduity, diligence, and kind attention uniformly displayed in the performance of his duties during that period, by the Secretary, Mr. Hudson, and in which we feel convinced we shall be joined by all those members of the society who have had communication with him.

LIVERPOOL MEETING, 1841.

We beg the attention of our readers to the subjoined list of prizes of the Royal Agricultural Society of England, to be awarded at the Liverpool Meeting in July next year. From this list, it will be seen that an addition of five pounds to the prize for yearling bulls has been made, in the classes for

Shorthorns, Herefords, and Devons. In the class for cattle of any breed or cross, not Shorthorns, Herefords, or Devons, a very considerable addition has been made to the prizes. A second prize of twenty sovereigns will be given to the second best bull, calved previously to the 1st of January, 1839. A second prize of fifteen pounds will be given to the second best yearling bull, and a second prize of ten pounds to the second best cow in milk; being an increase of prizes in this class over each of the other classes of forty-five pounds. In the class for horses, additional prizes are offered; for the second best cart stallion for agricultural purposes, twenty sovereigns, and for the second best cart mare and foal ten sovereigns. The prize for stallions for breeding hunters, coach-horses, or roadsters, is altogether omitted. Now it cannot for a moment be questioned, that there was great impropriety in uniting the three different classes of horses into one prize, but we must confess we see no reason for the total omission of prizes for these sorts of animals. It may perhaps be considered, that the horse for agricultural purposes is more practically and generally useful, and therefore demands a greater degree of attention; but we nevertheless do not think, that the encouragement of a good breed of hunters, roadsters, and carriage horses, is a subject unworthy the Royal Agricultural Society. There is a certain class of horses that are commonly employed in stage-coaches, which will soon be in a great degree superseded by the use of the rail, as it is now cantly styled. But we do not anticipate seeing for some time to come, a country gentleman following the hounds on a steam horse, or the use of the roadster or the carriage-horse rendered unnecessary by the application of steam power. The English hunter and the English coach-horse are unequalled in the world, and we therefore cannot but regret that encouragement to maintain that superiority has not been held out by the society. In each of the classes for sheep, an additional prize is offered for the second best ram of any age. In the class for pigs, an additional prize is offered for the second best boar.

We are gratified in observing that the sum of 200*l*. has been placed at the disposal of the council, to be appropriated to rewarding the exhibition and trial of implements. Improvement in agricultural machinery is of the utmost importance to the farmer. This liberal sum, placed at the disposal of the council, with the prize of fifty sovereigns, offered for the best essay on Agricultural Mechanics, will, we trust, arouse the energies of those persons who devote themselves to the study of this subject. Here, however, we cannot but repeat the regret which we have on several former occasions expressed, that no direct encouragement is offered for good cultivation. Surely, if it be of importance that agricultural implements should be made upon the most effective and economical principles, both as to cost and power requisite to work them; it is of equal consequence that the hand which uses them and the head which arranges and directs the various operations to be performed, should meet with equal encouragement. An efficient implement in the hands of an unskilful workman will be comparatively inefficient; and

an efficient implement in the hands of an efficient workman will, at the year's end, exhibit very different results when directed by the skilful or unskilful master. A reference to the prizes, offered by the Liverpool Agricultural Society, whose members meet annually to the number of twelve and fourteen hundred, will show, that in the very district in which the Royal Agricultural Society will hold its next meeting, this subject is deemed worthy of attention.

PRIZES FOR 1841.

[The whole of the following Premiums refer to the year 1841, but the President and Council have likewise decided on the amount and subjects of the Prize Essays for the year 1842; and these also, when their terms and conditions have been determined, we shall lay before our readers on a future occasion.]

PRIZES FOR IMPROVING THE BREED OF CATTLE, 1841.

CLASS I.—SHORT-HORNS.

	SOVS.
To the owner of the best Bull calved previously to the 1st of January, 1839	30
To the owner of the best Bull calved since the 1st of January, 1839, and more than one year old ..	20
To the owner of the best Cow in milk	15
To the owner of the best in-calf Heifer, not exceeding three years old	15
To the owner of the best Yearling Heifer	10
To the owner of the best Bull Calf	10

CLASS II.—HERFORDS.

To the owner of the best Bull calved previously to the 1st of January, 1839	30
To the owner of the best Bull calved since the 1st of January, 1839, and more than one year old ..	20
To the owner of the best Cow in milk	15
To the owner of the best in-calf Heifer, not exceeding three years old	15
To the owner of the best Yearling Heifer	10
To the owner of the best Bull Calf	10

CLASS III.—DEVONS.

To the owner of the best Bull calved previously to the 1st of January, 1839	30
To the owner of the best Bull calved since the 1st of January, 1839, and more than one year old ..	20
To the owner of the best Cow in milk	15
To the owner of the best in-calf Heifer, not exceeding three years old	15
To the owner of the best Yearling Heifer	10
To the owner of the best Bull Calf	10

CLASS IV.—CATTLE OF ANY BREED OR CROSS—Not qualified for the foregoing Classes.

To the owner of the best Bull calved previously to the 1st of January, 1839	30
To the owner of the second best do.	20
To the owner of the best Bull calved since the 1st of January, 1839, and more than one year old ..	20
To the owner of the second best do.	15
To the owner of the best Cow in milk	15
To the owner of the second-best Cow in milk ..	10
To the owner of the best in-calf Heifer, not exceeding three years old	15
To the owner of the best Yearling Heifer	10
To the owner of the best Bull Calf	10

CLASS V.—HORSES.

To the owner of the best Cart Stallion for agricultural purposes	30
To the owner of the second-best do.	20
To the owner of the best Cart Mare and Foal for agricultural purposes	15
To the owner of the second-best ditto	10

PRIZES FOR IMPROVING THE BREED OF SHEEP.—1841.

CLASS VI.—LICEESTERS.

To the owner of the best Shearling Ram	30
To the owner of the second-best ditto	15

To the owner of the best Ram of any other age	SOVS. 30
To the owner of the second-best ditto	15
To the owner of the best pen of five Ewes suckling their Lambs at the time of showing	10
To the owner of the best pen of five Shearling Ewes	10

CLASS VII.—SOUTH DOWNS OR OTHER SHORT-WOOLLED SHEEP.

To the owner of the best shearling Ram	30
To the owner of the second-best ditto	15
To the owner of the best Ram of any other age	30
To the owner of the second-best ditto	15
To the owner of the best pen of five Ewes suckling their Lambs at the time of showing	10
To the owner of the best pen of five shearling Ewes	10

CLASS VIII.—LONG-WOOLLED SHEEP.—Not qualified to compete in class VI.

To the owner of the best shearling Ram	30
To the owner of the second-best ditto	15
To the owner of the best Ram of any other age	30
To the owner of the second-best ditto	15
To the owner of the best pen of five Ewes suckling their Lambs at the time of showing	10
To the owner of the best pen of five shearling Ewes	10

CLASS IX.—PIGS.

To the owner of the best boar	10
To the owner of the second-best ditto	5
To the owner of the best breeding Sow*	5
To the owner of the best pen of three breeding Sow Pigs of the same litter, above four and under nine months old ..	10
† It is to be stated in the certificate of the sow, how many pigs she produced in her last litter, and reared to the time of weaning.	

CLASS X.—EXTRA STOCK, ROOTS, AND SEEDS.

For Extra Stock of any kind, not shown for any of the above Prizes, and for Roots, Seeds, &c., Prizes may be awarded and apportioned, by the Committee and Judges, not exceeding in the whole 50

MACHINERY.

A sum not exceeding 200*l.* to be at the disposal of the council, to be by them apportioned for rewarding the exhibition and trial of Implements, if they should so think fit.

ANY IMPLEMENT.

For the invention of any new Agricultural Implement, such sum as the Society may think proper to award.

SEED WHEAT.

1. Thirty Sovereigns, or a piece of Plate of that value, will be given to the Exhibitor at the Liverpool Meeting of the best 14 bush. of White Wheat, of the harvest of 1840, and grown by himself.

2. Thirty Sovereigns, or a piece of Plate of that value, will be given to the Exhibitor at the Liverpool Meeting of the best 14 bush. of Red Wheat, of the harvest of 1840, and grown by himself.

(12 bushels of the wheat will be sealed up by the Judges, and one of the remaining bushels of each variety will be exhibited as a sample to the public. At the public meeting in December, 1842, the Prizes will be awarded.) The three best samples of the Wheat, without distinguishing between the three, will be selected by Judges appointed at the Liverpool Meeting, and will be sown under the direction of the Society, in the Autumn of 1841, by three farmers, who will make their report, upon which the Prize will be awarded. Ten Sovereigns will be given, at the Liverpool Meeting, to the exhibitors of each of those three samples.

GORSE-CRUSHING MACHINE.

Twenty Sovereigns, or a Piece of Plate of that value, will be given for the cheapest and most effective Gorse-crushing Machine.

1. The machine produced must be on a working scale, and at a cost that will be attainable by the occupiers of the smallest farms.

2. It must be capable of reducing the material to a pulpy state for the mastication of ruminating animals, as cows and sheep.

PRIZE ESSAYS AND REPORTS OF EXPERIMENTS FOR 1841.

1. VARIETIES OF WHEAT.

Twenty Sovereigns, or a Piece of Plate of that value, will be given for the best Report on the Comparative Merits of different varieties of wheat. Competitors will be required to state,—

1. Preparation and quantity of the seed; time and method of sowing; relation to preceding and following crops; nature of the soil.
2. Power to withstand severe winters.
3. Time of flowering, and of maturity.
4. Tendency to degenerate, and liability to disease.
5. Amount of produce in grain and straw, and the relative quantities of flour and offal.
6. Quantity of bread produced from 18lbs. of flour according to the process described by Colonel Le Couteur, in the Journal, No. 3 (1839, page 115.)

Not less than a quarter of an acre to be planted with each variety.—It would be desirable that competitors should consult Colonel Le Couteur's Work upon Wheat.

2. VARIETIES OF BARLEY.

Twenty Sovereigns, or a Piece of Plate of that value, will be given for the best Report on the Comparative Merits of different Varieties of Barley. Competitors will be required to state,—

1. Preparation and quantity of the seed; time and method of sowing; relation to preceding and following crops; nature of the soil.
2. Power to withstand drought or extreme wet.
3. Tendency to degenerate, and liability to disease.
4. Time of flowering and of maturity.
5. Amount of produce in grain and straw.
6. Malting qualities.

3. VARIETIES OF TURNIPS.

Ten Sovereigns, or a Piece of Plate of that value, will be given for the best Report on the Comparative Merits of different Varieties of Turnips. Competitors will be required to state,—

1. The comparative produce per acre of each variety treated of.
2. The nutritive qualities as compared with weight; distinguishing—
 - a. The varieties possessing early maturity appropriate for autumn stocking.
 - b. The more productive and nutritive kinds for general feeding; and
 - c. The more hardy varieties for spring and late consumption.

4. EFFECTS ON SUBSEQUENT CROPS OF WHEAT.

Twenty Sovereigns, or a Piece of Plate of that value, will be given for the best account of the effects of crops of beans, clover, vetches, potatoes, rye-grass, or any other crop, upon a subsequent crop of wheat. Competitors must state—

1. The soil on which the experiment was tried.
2. The crop preceding the wheat, and the manner of cultivating it.
3. The quantity of manure applied.
4. Whether fed or mown, and the quantity of produce if mown.
5. The species of wheat sown.
6. The manner in which the wheat was cultivated; and if manured, the quantity applied.
7. The produce in bushels of the crop of wheat.
8. Any other particulars that may seem important.

5. FOOD FOR LABOURERS.

Ten Sovereigns, or a Piece of Plate of that value, will be given for the best directions to enable labourers to prepare wholesome, nutritious, and palatable food, in the most economical and easy manner.

As the object of the Society in offering this prize is to procure such instructions for agricultural labourers as may enable them to supply themselves with the

greatest quantity of nutriment which the means at their command will produce, and to prepare a warm, comfortable, and nutritious meal for themselves and their families when they return home from their day's work, the competitors for it are requested to observe—

1. That the receipts must be given in such a plain manner as may render them available to a labourer or his wife, who are unaccustomed to cookery.
2. That the receipts must be such as may be used without requiring any apparatus which an agricultural labourer does not usually possess.
3. That they shall not require the use of any ingredients which he may not easily procure, either from his garden or in agricultural villages. This condition is not intended to preclude the recommendation of fish as a part of any dish.
4. The cost of the different fishes for which receipts are given must be accurately stated.

6. APPLICATION OF LIME.

Ten Sovereigns, or a Piece of Plate of that value, will be given for the best account of experiments on the application of lime as a manure. The competitors will be required to state—

1. How many years they have used lime as a manure, and how many acres they have limed each year.
2. What quantity they have put on per acre, and on what sort of soil.
3. At what time of the year, and for what crop.
4. Whether with or without manure, in what manner applied, and with what effect on the crop, and what on the succeeding crop.
5. The price of the lime; whether they continue to use it; the chemical description of lime they use; and any particulars generally respecting lime.

7. NITRE AND CUBIC-NITRE.

Twenty Sovereigns, or a Piece of Plate of that value, will be given for the best account of experiments on the application of nitrates as manures, including saltpetre (the nitrate of potash) and cubic-nitre (the nitrate of soda). Competitors will be required to state—

1. The quantity and mode of these applications, whether used before sowing, along with the seed, or after the blade is up.
2. Every particular of each experiment; and a comparison made with the same quantity of ground sown both without manure, and also with common yard-dung; stating the value of the manure in every case.
3. The result at different periods of the growth.
4. The conclusion come to from the experiments.
5. Not less than a quarter of an acre to be taken for each experiment; and to be varied as much as possible.

8. IMPROVEMENT OF PEAT SOILS.

Twenty sovereigns, or a Piece of Plate of that value, will be given for the best essay or report on the most successful means by which the improvement of peat soils may be effected. Competitors will be required to state the following particulars:—

1. Description of the mode, as far as it can be ascertained, in which the peat has been formed, whether by rain-water ledging on the surface, the oozing of springs, or under a body of stagnant water.
2. Description of the plants, from the decay of which the peat appears to be formed, and of the state of decomposition in which they are found.
3. Chemical account of any acid or bitter principle injurious to vegetation which may be found in the peat.
4. Account of any substance applied to the peat, either for correcting its chemical defects or improving its consistence.
5. Level of the water in the neighbouring ditches in winter and summer.
6. General treatment and mode of cropping.

9. SUBSOIL AND TRENCH PLOUGHING.

Twenty Sovereigns, or a Piece of Plate of that value, will be given for the most satisfactory experiment on the comparative merits of the two processes of the Sub-

soil and Trench Ploughing. The Society will require from Competitors :—

1. An accurate description of the ploughs used ; and also
2. Of the quality and state of soil and subsoil, with an estimate of its annual value before the commencement of the operation.
3. An account of the drains cut (if any), their depth and distance from each other.
4. A detailed statement of the subsoil and other ploughings to which the grounds have been subjected.
5. An account of any manure expended.
6. Of the bulk of produce of each crop.
7. Of the total expense of the operation so far as it has proceeded, and—
8. An authentic estimate of the improved value of the land resulting therefrom.

As the object of the Society is to ascertain as far as possible the advantages of subsoil ploughing, (in which the subsoil is divided by the plough but left in its original situation), and of trench-ploughing, (in which the subsoil is not only divided but is also brought to the surface), they strongly recommend to competitors that the two processes should be conducted on a piece of ground fairly divided into two lots of equal quality, and that the drains cut in each lot, as well as any assistance afforded by manure, should be similar on each of the lots.

10. SINGLE-HORSE CARTS.

Ten sovereigns, or a piece of plate of that value, will be given for the most satisfactory account of any experiments to compare the relative advantages of the single-horse carts which are generally used in Scotland, with any mode of conveying agricultural produce which is practised in any part of England, or in any foreign country ; having regard to economy of labour both of men and animals, quickness of work, and facility in loading and conducting the carriage.

11. AGRICULTURAL MECHANICS.

Fifty sovereigns, or a piece of plate of that value, will be given for the best Essay on the present state of Agricultural Mechanics, and on the improvement of which the various implements now in use may be susceptible.

N.B.—General conditions for all experiments on soils and manures.

1. The nature and depth of the soil.
2. The proportions of clay, sand, lime, or other substances, of which the soils are composed ; or otherwise to send specimens of the soils (in quantities of a pound or pint of each variety) to the secretary, on his application for them.
3. The nature of the subsoil.
4. When the ground is not level, the degree in which it slopes, and the direction (north, east, &c.) of its inclination, as found by the compass.
5. The two or three preceding crops ; the manure put on for them, and the produce of these crops.

These essays and reports to be sent in to the secretary on or before March 1, 1841.

ANALYSIS OF SOILS.—At the recent meeting at Cambridge, Professor Buckland stated, that it was important to the English agriculturist to know that there is a laboratory in London, in the Museum of Economic Geology, attached to her Majesty's Board of Woods and Forests, in Craig's Court, Charing Cross, to which any individual may send one pound of any soil of which he wishes to know what are the ingredients, and for a fixed fee (the Professor believed twenty shillings) obtain an exact analysis of the same, conducted by Mr. Richard Phillips, whose name has long been in the first rank of the analytical chemists of Europe.

THE WIREWORM.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—I perceive by a letter in the *Mark Lane Express* of the 27th ult., by Mr. Hillyard, that he considers the wireworm to be the larva of the "Harry-long-legs," or, as it is called here, "Jenny-spinner." Mr. Hillyard is in error in supposing this, as the Harry-long-legs is produced from the grub that is frequently so destructive to the oat crop. I, many years ago, tried an experiment, which completely satisfied my mind ; and, as it may be interesting to some of your readers, I will detail it. I had a part of my oat crop very much destroyed by the ravages of the grub, and it having been stated that salt would destroy it, I resolved to try the double experiment of whether it would have that effect, and also what the grub changed into. To effect this I had a considerable number of them put into two earthen vessels—this was about the beginning of May—along with a quantity of soil, and also some oats ; and in the one vessel I put a quantity of common salt, and in the other I put none. I had them both well secured by having a piece of cloth tied closely over the top, which of course admitted air, while it prevented the grubs from escaping, at the same time that it hindered any thing to find its way in. I watched their progress with attention. Some time in the month of June they became rather larger in size, and not so active, and soon after went into the chrysalis state, and remained torpid till some time in the month of July, when they crept out of the hard husky skin of the aarelia, and appeared in their perfect form of Harry-long-legs ; and, as if to put all dispute out of the question, one of them had been unable to get clear of its covering, but was half way out, and dead. In the pot where there was no salt the oats grew quite luxuriantly, but in the other they did not vegetate at all, from the quantity of salt put in, but the grubs were nevertheless just as healthy as in the other where there was none ; thus setting at rest any hopes of killing them by the use of salt.

The appearance of the wireworm is very different from that of the grub. The former is a rather long, small, hard worm, of a yellow colour ; while the oat-grub is rather thick and soft, and of a dark brown or kind of green gray colour ; and their habits too are different, as the latter is commonly found in a rather damp part of a field, where the oats will suffer much from them, while the dry parts will be comparatively free, which seems to shew that these insects deposit their eggs in damp situations in preference to dry ones. The wireworm is more commonly found in dry situations, where they are sometimes very destructive to wheat, spring-sown ; the generality of failures of which I am inclined to attribute to the wireworm. They are often numerous in potato ground, and where they are so, if the wheat was not sown till the spring, they would almost entirely destroy it ; but when sown in the autumn, the blade acquires some strength before the spring, and thus prevents them injuring it so extensively ; and as they are probably in a kind of inactive state during the winter months, it escapes their ravages. Judging from appearance the wireworm would seem to remain in the same state throughout its existence, as you will find it in the same place for years, and while the land is in different kinds of management, and almost equally destructive to every kind of crop, except grass ; and that is perhaps owing to the nature of its roots. There is some land in my neighbourhood where red

R

clover almost invariably fails, and has done so for years. It will be quite rank and healthy like in the autumn when the grain crop is cut, and in the following summer there will be just a patch here and there amongst the hay, and I am very much inclined to suspect the wireworm for this. The clover being tap-rooted, allows an excellent opportunity for the operation of its destructive powers. It is very easy to know turnips that are much affected by it; in a hot sunny day, their leaves will droop, and have a withered appearance. It is rather singular by what instinct crows are so well acquainted with turnips affected with wireworm; they will pull them up by the root, and clear off considerable patches of them. I never knew an instance of either wheat or barley being eat by the grub, but oats very commonly, and generally in clean well-conditioned land. They may be found in quantities when the oats appear above the ground, by turning back the furrow-slice, and at sunrise they may be seen creeping above the surface. An experiment similar to the one I tried might determine the nature and habits of the wireworm, and by knowing which a step might be gained in the knowledge how to destroy it, or in some degree to counteract its ravages. I have no faith in the power of salt being sufficient to effect it, and even if it had a tendency to destroy it, the quantity must be very great before there could be the most distant chance of succeeding.

I am, Sir, your obedient servant,
Aug. 6, 1840. A CUMBERLAND YEOMAN.

ON SOILING COWS, &c.

SIR,—In reply to your correspondent Tyro, respecting Soiling Cows, I beg to say that for four years I have soiled the whole of my dairy cows, and quite approve of the system. The two last years of the four I kept 24 cows in the stall during Summer upon green food, consisting of seed grass, good meadow grass, red clover, the lower leaves of the Scotch cabbage stripped off, and also the same of my mangel wurzel plants; all these were given as they came in, in the Summer, in five fodderings per day. Two men with a horse and cart are required to cut and carry the grass, &c., and fodder the cattle, and also to clean out the cow-house, water and tether the cows and assist the milking twice a day. No Vetches are given, as they are too heating for the purpose; and *too much red clover* was found to give the cows a tendency to cast their calves, though there is no grass known which produces more milk (and this probably is the cause of the effect above stated). The greatest difficulty is to have the grass, &c. come in *in proper succession*, so as not to be too old, on the one hand, nor too young and short, on the other; but this, after a little experience, may be accomplished. The result is, I think, as favourable as can be wished; my cheese was, at least, equally good as in former years, the quantity *greater* than when the cows were regularly kept in the pastures; and the cows were so much better in condition and appearance that I received from two to three pounds more per head for my spare cows, about the end of October, generally, than in other years, when pastured. They *rarely* go barren; but whenever that is the case, a ready sale is ensured by their good condition, for feeding. The cowhouse doors are kept open day and night in warm weather, to give the cows plenty of air; they are therefore *cool*, and quiet from flies; they rest well and are in every respect better; indeed,

so conscious are they of the benefit of the house, that no man, or number of men, could have kept my cows from breaking the fences and returning to the cowhouse, as I found to my cost when trying the experiment one warm day, and I was obliged to admit them again to their cool and quiet quarters.

I have no doubt that cows or oxen may be fed to great advantage in the stall in the same way.

One great advantage also is, that *half of the land* usually allowed to a milking cow as pasture will be sufficient for soiling. Another, that *very much dung* is made, and laid upon the land *where most wanted*, and if peat soil, saw-dust, or tanners' bark can be had, and placed *behind* the cows plentifully, an amazing quantity is produced, which may be spread upon the land as it is mown, and this, with the *wash from the cowhouse* carted upon the land in a barrel in the usual way, will be abundantly sufficient to keep the mown ground in *high condition*. One other benefit I will enumerate, which is, any cow failing to milk well during the Summer, may be permitted to go "dry" and be fed very speedily, as their superior condition upon the soiling system ensures this, which is no small benefit in a large dairy. Any farther information I can give is at the service of your correspondent. I am Sir, your obedient servant, M. O.

P.S. Can any of your correspondents inform me where the Guinea Grain wheats, and Brown's ten-rowed wheat are to be had, and the price per bushel?

I give you below a recipe for Foot-rot in sheep, which, though an old remedy, is *infinitely superior to Butyr of Antimony*, as recommended by some of your correspondents, and gives the sheep no pain, which is far from being the case with antimony.

Let the *druggist* mix as follows:—

Three oz. verdigris, 4 oz. alum, $1\frac{1}{2}$ oz. white mercury, 4 oz. vitriol, 1 oz. white copperas; reduce them to a fine powder, and mix them together. Then boil them in one quart of white wine vinegar, and it is fit for use. Pare the feet of the sheep affected, and apply the mixture from a bottle, with a piece of wood a little *hards* at the end, after shaking the bottle. The sheep should be kept in a dry place for an hour after dressing. I have used various remedies for many years, but the above is by far the best I ever saw or heard of.

ON WINTER TARES.

SIR,—In answer to your correspondent "Northern," I have sown the winter tare for many years, and always to feed, taking care to have them next to clover, grasses, &c. I feed the tares off as occasion may require, never letting them be eaten down too bare; they will furnish abundance of food, and will bear feeding upon the whole summer; my sheep feed over the whole field, and I now have them on one of the cleanest and best field of tares in the kingdom. They may be ploughed up and sown with turnips, or fed all the summer, and left for a wheat tilth; those who sow tares ought to be particular as to the variety, all Foreign tares are Spring tares; many farmers last autumn sowed Spring tares by mistake, and consequently the crops were all destroyed by the frost; a genuine winter tare, will withstand the severest winter; never seeding any myself, I always buy them of the growers; and I have never yet been deceived. Having Italian and other grasses which produce early seed, I do not sow tares early, as most farmers do. I have tried both, and I find the late sown the best; I have stated sowing tares; I always drill mine at nine inches. VERITAS.

ALLOTMENT SYSTEM IN RUTLAND, 1840.

On Monday and Tuesday, the 3rd and 4th of August, Richard Westbrook Baker, Esq., of Cottesmore, with a party of clergy and distinguished agriculturists, proceeded as in former years to examine and award prizes to the most meritorious occupiers of allotments of land upon Lord Barham's estates, under rules we believe arranged purposely for their management some years since, under the patronage of the late Sir Gerard Noel. The party expressed themselves highly gratified with the examination; and no less so, with the handsome, hospitable, and kind manners of their friend who has conducted with so much zeal and ability for eleven years this admirable system for the encouragement of industry and comfort of the labouring classes. The Judges were Messrs. Morris, Burgess, Berridge, and Pickering. The award was as follows:

UPPINGHAM.—*West Field.*

1st prize, No. 11, James Elliott, 10s.; 2d prize, No. 8, Thomas Nutt, 7s.; 3d prize, No. 14, John Mould, 5s.—given by Lord Barham.

Commended, No. 6, G. Crowden, No. 13, W. Baines, 2s. each, by Lord Barham.

East Field.

1st prize, No. 9, John Forster, 10s.; 2d prize, No. 2, Michael Cant, 7s.; 3d prize, No. 8, Thomas Dunmore, 5s.—given by Lord Barham.

Commended, No. 1, J. Coulson, No. 12, G. Nutt, 2s. each, by Lord Barham.

The Rev. J. D. Dimock, to all the unsuccessful candidates, in both fields, 1s. each, for good cultivation generally.

RIDDLINGTON.—*Old Allotments.*

1st prize, No. 7, Edward Russell, 10s.; 2d prize, No. 6, John Barfield, 7s.; 3d prize, No. 3, Wm. Wright, 5s.—given by the Rev. C. Swann.

Commended, No. 10, Henry Jackson, 2s., by Lord Barham.

Under the 11th Rule, "It is expected that every occupier shall attend some place of worship at least once every Sunday."

For "general good conduct," No. 7, Edward Russell; No. 3, William Wright; No. 9, Thomas Manton; No. 8, Edward Russell, jun., 2s. each, by Lord Barham.

No. 5, Geo. Pennystone, 1s. by Lord Barham.

No. 1 in this field disqualified under the 14th Rule.

New Allotments.

1st prize, No. 7, Robert Manton, 10s.; 2d prize, No. 5, William Manton, 7s.; 3d prize, No. 1, George Webb, 5s.—given by Lord Barham.

Commended, No. 3, John Dunmore, 2s., by Lord Barham.

Under the 11th Rule, 2s. each to all the eight occupiers, by Lord Barham.

EXTON.

1st prize, No. 57, Thomas Speede, 10s.; 2d prize, No. 32, Luke Hibbitt, 7s.; 3d prize, No. 5, Thomas Bullimore, 5s.; 4th prize, No. 24, John Young, 3s.; 5th prize, No. 57, James Speede, 3s.; 6th prize, No. 56, William Cross, 3s.—given by Lord Barham.

Commended, No. John Chamberlain; No. 2, Everard Cole; No. 25, William Smith; No. 45, John Fant's Widow; No. 51, Daniel Buckle; No. 53, Amos Hibbitt; 2s. each, given by Lord Barham.

WHITWELL.

1st prize, No. 2, Daniel Smith, 10s.; 2d prize, No. 1, Edward Smith, 7s.; 3d prize, No. 4, John Bolland, 5s.—given by Mrs. Ellicott, sen.

Commended, No. 10, Rt. Allen's Widow, 3s. by Lord Barham.

Under the 11th Rule, J. Hibbitt and H. Hibbitt, 2s., by Lord Barham.

COTTESMORE.

1st prize, No. 9, John Tyler, 10s.; 2d prize, No. 19,

John Plowright, 7s.; 3d prize, No. 14, Edward Osborn, 5s.—given by the Rev. Henry Neville.

Much commended, No. 1, Geo. Allett, 3s. by Lord Barham.

Commended, No. 7, Robert Hill; No. 18, Matt. Sharpe's Widow; No. 21, Thomas Starling's Widow; No. 23, William Cox; 2s. each, given by Lord Barham.

BARROW.

1st prize, No. 5, John Leeson, 10s., 5s.; 2d prize, No. 7, Edward Clarke, 7s., 3s.; 3d prize, No. 2, William Huffill, 5s., 2s.—1st sum given by the Rev. H. Neville; 2d by the Rev. J. Hinman.

Commended, No. 9, Leatherland, jun., 3s., by Lord Barham.

Under the 11th Rule, No. 1, Widow Munton; No. 4, Mary Huffill; No. 3, Henry Stubbs; No. 5, John Leeson; No. 8, Leatherland, sen.; No. 9, Leatherland, jun.; No. 10, John Freeman; 2s. each, given by Lord Barham.

Field v. Field, comparative merits, quality of the land, situation, clean and useful husbandry, general management, and number of years under the system, awarded to Riddington Old Allotments, 1s. each to all the occupiers (excepting No. 1,) given by Lord Barham.

The Ransome prize of one sovereign to the occupier of the best cultivated allotment in any of the parishes, was awarded to No. 7, Edward Russell, Riddington Old Allotments.

The cropping generally was good throughout the whole of the Allotments, and they were well cultivated.

Under all the circumstances relating to this charming work, no former year offered greater gratification. The extraordinary profit shown to be obtainable from a small portion of land is astonishing, and is mainly owing to a judicious rotation of cropping and annual examination.

—*Lincoln Chronicle.*

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—I see a correspondent of yours wishes to be informed where he can be supplied with some *pure* Berkshire pigs; he is rather too late in his application, or I should have been happy to have sent him some of each sex, which, I think, would have given him satisfaction. I distributed a number this spring about two months old, which is the right age, as they can be easily packed and sent almost any distance without risk. I only now have two sows to spare, five months old, which I fear would be too large to send far.

I have exchanged the land on which I tried the the experiment with coal tar, but on looking at it this week, I see the improvement on the present crop of beans is still more conspicuous than in the wheat last year, thus proving it a lasting and good manure; but I fear the difficulty of getting a regular supply will curtail its usefulness for agricultural purposes. W. C. Johnson says in a paper he has lately written, "Mr. Bowly's experiment of applying coal tar as a manure failed because he put too much." I think he can scarcely call it a failure, as I anticipated the results; I knew it would destroy the seeds in the first instance, the experiment was to see its effects on future crops. If W. C. Johnson can inform us any way of increasing its volume, so as to render it safe to apply it in a less concentrated and liquid state it would be of great service. Believe me truly yours,

EDWARD BOWLY.

Siddington, Cirencester, July 17th.

DRUMMOND'S AGRICULTURAL MUSEUM.

In common, we believe, with the rest of our townsmen, we have long regarded with great interest, and no small degree of pride, the successful progress of our friends the Messrs. Drummond's Agricultural Museum, in this town. We find it difficult whether to admire more the enterprise and public spirit of the founders of the institution, or the intelligence and activity of the agriculturists of the district, without whose able assistance and encouragement the enlightened attempt of the Messrs. Drummond would necessarily have proved abortive. It affords, assuredly, a very decided proof of the superior intelligence of the Stirlingshire agriculturists, that not only should Stirling have taken the lead in the establishment of an institution of this kind, and that the success with which that attempt has been crowned, should have so far exceeded all reasonable expectations. Drummond's Museum was originally instituted in September, 1831. The articles exhibited consisted at first, we believe, exclusively of roots, seeds, and other agricultural products; and the period of exhibition was confined only to a few weeks. In the conclusion of the same year these gentlemen opened another agricultural exhibition on a more extensive scale. It comprised choice specimens of every important article connected with agriculture and gardening, which were accompanied with a description of the soil on which they were grown, the manure used in rearing them, and other particulars. Several fine specimens of the different kinds of grain were produced, also samples of Indian corn, potatoes, field turnip, carrot, mangel wurzel, clover, &c., and finally, a variety of the most improved implements of husbandry. This exhibition, though still only temporary (it continued, we believe, for three or four weeks,) attracted a good deal of attention in all quarters of the country, and was noticed in terms of high approval by most of the leading newspapers of the day. The exhibition was repeated in the following years with still increased success, and the attempt of the projectors having by that time attracted the notice and received the warm approbation of the most distinguished agriculturists both in Scotland and England, the Messrs. Drummond, in 1833, we believe, were encouraged to convert their temporary exhibition into a permanent one, and to devote several apartments in their warehouse to the purposes of a museum. In January, 1834, the Highland Society presented the Drummonds with their gold medal, for their spirited and valuable labours in the service of agriculture, and from that time to the present, the zeal and activity of the friends and founders of the institution have never flagged; its objects have been greatly extended, and its interest and importance continued rapidly to advance. Several reports on the museum, containing valuable communications on agricultural subjects, have been published under the auspices of the Messrs. Drummond. It will be interesting to our readers at a distance to be informed that the extent of the museum has latterly increased to such a degree that the apartments in which it was formerly contained have been found by far too small, and the Messrs. Drummond have, in the course of the present year, erected a large new building, and that the Stirling Agricultural Museum is now, in fact, one of the most prominent and elegant edifices in the burgh. It is situated in the lower part of the town, is of an oblong shape, composed of four flats, and adorned in front with a remarkably chaste and

elegant portico. The museum is principally contained in the upper part of the building, in two spacious halls, each measuring about 160 feet in length, and 21 in breadth. The eastern windows of the upper hall command an extensive prospect, comprehending the whole course of Stirling, with its beautiful boundary of the Ochils on the north, and reaching to the distant line of the Pentlands in the extreme south-east. It would be impossible, nor is it necessary, that within our present limits we should attempt to give any details of the contents of these elegant rooms. Few of our readers are unaware that the most prominent objects in the Museum are the agricultural implements (the collection of which, is probably unequalled in extent and completeness, either in this or any other country), the collection of seeds, roots, and plants, from all quarters of the globe, and models of almost every object of interest or value to the agriculturist. The collection of minerals has recently received considerable additions, and a portion of one of the large halls has been devoted to the exhibition of the various cloth manufactures (principally woollen tartans) of the neighbourhood, which, from the almost unequalled delicacy and beauty of their texture, impart a great additional attraction to the Museum. In extending their attention to the collection of such objects as those last mentioned, the Messrs. Drummond, however, appear never to have lost sight of the proper intention of the exhibition. The agricultural collection still occupies, as it ought to do, the largest and most prominent place in the Museum.

It is impossible, perhaps, to overrate the importance of a public collection of this kind. The comparatively imperfect means of intercourse and observation possessed by the agricultural population, render it an almost indispensable condition of progress or improvement in the cultivation of land. Without the means which a museum alone affords, of bringing immediately under the eye, the various inventions connected with agriculture, it appears altogether hopeless that any improved processes whatever, can ever come to be generally adopted. This, however, is too obvious to require any lengthened illustration. But in addition to persons directly engaged in agriculture, there is another class to whom Drummond's collection of implements is calculated to prove extremely beneficial. We allude to those who have any turn for mechanical invention. Among the machines in the museum, there are many which display a remarkable degree of ingenuity in their construction, and there is often in the different implements a curious variety of means for the accomplishment of similar purposes, which is admirably adapted to call forth, or give impulse to mechanical genius. We observed, for instance, on a recent visit, no less than five or six different machines, more or less cleverly constructed, for the slicing of turnips—an operation which one would not at first thought have conceived likely to call for any uncommon ingenuity or skill. This, however, is but one out of innumerable sets of implements from which many of the talented mechanics in our neighbourhood might obtain invaluable hints.

Our limits prevent us from at present adverting at greater length, to this admirable institution. We shall probably take an early opportunity of noticing a few of its more curious and interesting objects. In the meantime we shall have in some degree accomplished our purpose, if the few observations which we have presumed to offer, shall contribute in any degree to further the important objects of the Stirling Museum, or to suggest the introduction of similar institutions in other parts of the country. The benefi-

cial results which the formation of an agricultural museum in every market town in the country, would have in improving the cultivation of land, is undoubtedly quite incalculable, and it is extremely surprising that in such places as Haddington, Kelso, Dumfries, Lanark, Glasgow, Perth, and Aberdeen, no successful attempt should ever have been made to carry such an object into effect. We have much pleasure here in adverting to the spirited enterprise of Mr. Lawson, seedsman to the Highland and Agricultural Society of Scotland, in establishing a similar museum in Edinburgh, in 1833, now, we believe, merged into, and known as the museum of that Society, who have erected a spacious building for its reception, and which we may recur at a future time. We believe, from various circumstances in the character and habits of the agricultural class, that on no portion of the community, are collections of objects such as those in Messrs. Drummond's Museum, likely to produce so decidedly beneficial effects. This truth has nowhere been more distinctly proved, than in our own district, by the marked improvement which has taken place in the enterprise and intelligence of the neighbouring farmers within the last ten years—an improvement which it is impossible to attribute to any other cause than the establishment of such institutions as Drummond's Museum, and the Stirlingshire Agricultural Association—to the former, in all probability, scarcely less than to the latter.—*Stirling Observer.*

ON HORSE KEEP.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—I must apologize for intruding so frequently upon your valuable columns. Although I am at variance with most of your agricultural readers, they will not, I feel convinced, withhold a little information on the keep of cart-horses, which I am much in want of. Oats are now so dear that horse keep is very expensive, and as rice is generally considered to be a much more nutritious grain, and as rice can be bought for less than a penny a pound, whilst oats cost nearly a penny farthing, it has struck me that rice might be advantageously substituted for oats. I wish, therefore, to inquire,

Firstly—Whether there be any, and what objection to substituting *boiled* rice for oats in their manger victuals?

Secondly—Whether gruel made with wheat flour be objectionable?

Thirdly—Whether boiled barley be considered advantageous food for cart horses?

Fourthly—Whether gruel made from rye-flour would be nutritious? And if not,

Lastly—Whether rye can be given them in any other form?

Thanking you for your indulgence in inserting my epistles, I remain, Sir, your most obedient servant,
Bor Common, Middlesex, July 13. W. S.

SIR,—In perusing your columns of the 27th, which as usual were filled, not with political sarcasm and useless discussions, but with useful information and practical inquiries, I observed five questions from one of your correspondents, upon the keep of cart-horses. It is quite out of my power to answer them all, but if the result of five months' trial and observation upon boiled barley be deemed worthy of a place in your paper, it is very much at your service.

The horses upon which the experiment has been made are constantly employed at heavy work upon the road, and upon an average travel 140 miles per week. Their former keep was (for four horses) four bushels beans, four bushels oats, and four cwt. bran per week. At the beginning of last March the beans and oats were discontinued, and barley substituted, of which we found they did not require more than four bushels, and that consequently (including the expense of boiling three times) it is a saving of full one pound per week. No other alteration has been made in their keep or their work, they have since been as healthy and active as they could be upon any corn, and are now in high condition.

Such are the simple facts of the case, upon which I need make no comment; we have derived much advantage from the practice ourselves, and should this statement induce any of your readers to realize the same, or be the means of eliciting any further information on the subject, it will be a source of gratification to your most obedient servant, A. S.

Bath Town Mills, July 30, 1840.

SIR,—The subject of W. S.'s letter (July 27) being more agreeable I believe to most agricultural readers than some former ones on political economy, I communicate with pleasure the result of our experience to the third query.

Our barley having unfortunately for us this last season been nearly unsaleable, it has in consequence been liberally supplied to every description of stock, the horses have had it whole, or coarsely ground, with, and without, clopped straw and chaff, also boiled until almost to the consistence of jelly; of this they are very fond, and where convenient, and fuel no object, the most economical plan: it appears to have agreed with them quite equal to oats; but where speed and endurance is required, as in hunting, it is not recommended. Rye is only known here by name; in Flanders they reckon rye-bread superior to oats for travelling horses and they mix rye-meal with their stable water.

I have at various times tried experiments with the food of horses, but they have not taken to them readily, and I have not persevered, being fearful of throwing them out of condition, well knowing, that neither horse or man can stand our work upon short commons.

A DEVONSHIRE FARMER.

South Hams, Aug. 4.

WARREN'S FARMERS' ACCOUNT BOOK.—

It must be very gratifying and encouraging to the author of this valuable Account Book, to receive continually the qualified approval of the leading agriculturists of the country, particularly at the Cambridge Meeting. The work needs only to be examined to prove that such eacommiums are due. Its methodical arrangement, its copiousness, its simplicity, render it invaluable to the farmer. By consulting it, it would almost be difficult for him to overlook any branch of his income or expenditure; there being columns arranged that would suffice for the very great variety of stock and operations in a large establishment. Above all, the farmer could, with little trouble, see at one view, his profits or his loss, at any time of the year: without such a monitor, any farmer would be pursuing a most dangerous course, and no language could be too strong in urging him as speedily as possible to keep systematic accounts. It is to be hoped that schoolmasters will prize the school edition as they should do—and by the use of it, instil right principles into the minds of farmers' sons whom they may have to instruct.

PROBUS FARMERS' CLUB.

At the last monthly meeting of this club, in consequence of the absence of the lecturer appointed for the evening, several subjects connected with agriculture were discussed by the members present, when some exceedingly interesting facts were elicited.

The use of salt as a manure was first considered. One member had tried the common fish salt, after it had been used for curing pilchards, and might thus be supposed to contain no small portion of the oil with which that fish, particularly when taken in summer, abounds. This he had applied to the extent of 30 bushels per acre, but without any beneficial effect; indeed, in some places, where it had been laid on tolerably thick, it destroyed the grass for a short time. He had also employed it as a preparative for turnips, but without perceiving either any good or ill effects from its application.—Another member had used it in preparing his land for barley; and he believes that it did considerable mischief to the crop. He had also used it for turnips to the extent of 20 bushels to the acre, mixing it with his heaps of dung, and letting it remain about a month before being carried out in the field. As it was only used on a portion of one of his fields, he had a very excellent opportunity of testing its value; and he was of opinion that it was very injurious, as his plants scarcely grew where it was employed, whilst in the other portion of his field he had an excellent crop.

The use of Lime as a Manure was then considered. A member condemned the practice of mixing lime with heaps of manure, and leaving it for a month or six weeks previously to its being used. He contended that it should be ploughed into the soil as quickly as possible, in order that its caustic qualities might act upon the vegetable matter contained therein, and thereby bring it into a state of more rapid decomposition and solution, so as to render it a proper food for plants. It was, he said, upon this circumstance that the operation of lime as a preparation for the wheat crop depended, as well as its efficiency in fertilizing peats, and in bringing into cultivation all soils abounding in hard roots, or dry fibres, or any sort of inert vegetable matter.—In opposition to this opinion, a member asserted that he had for many years been in the habit of mixing lime with his dung, and so leaving it for a week or fortnight previously to its application. He had always found this practice to succeed well, and he mentioned two or three parishes in particular where it was invariably followed. He was of opinion, that, however quickly the lime might be used, it remained but for a very short time in a caustic state, at least to such a degree as to produce any great effect upon the soil; and it was not in this condition that it produced any beneficial effect, but rather in its original carbonaceous comminuted state. It had very frequently been observed, that the first year after lime was applied to the soil, its effects were inconsiderable in comparison of those which it produced in the second and succeeding years.

This interesting question was considered at some length, but as it will come before the society again at the next meeting in September, in a lecture on chemistry as connected with agriculture, we refrain from entering any further into it at present.

After this, a very interesting conversation took place on the comparative merits of the various *Artificial Manures* which have been lately employed, particularly for turnips. It appears that

several of the farmers in Probus and the adjoining parishes have put the efficacy of these different manures to the test, by instituting experiments with malt-screenings, wood-ashes, nitrate of soda, bone-dust, and Lance's granulated manures, drilling them in with the turnip seed, side by side in the same field; and the result is, that Lance's carbonized humus has taken the lead of all the others, having given a most extraordinary stimulus to the young plants, thereby getting them quickly on to that state in which it is found that they are free from the ravages of the wire-worm, and the other destructive insects which prey upon them. On the value and importance of the turnip crop to the farmer, it is unnecessary to expatiate, as it not only enables him to supply our markets with an abundant store of fresh and wholesome provisions during the winter, instead of the salted food upon which our ancestors had, at that season, principally to depend; but also, that, while it supersedes the necessity of fallowing, it imparts to the land a degree of fertility which insures, under proper management, a succession of crops afterwards. It may indeed be called the "sheet-anchor" of light soil cultivation, and the base of the alternate system of husbandry, to which every class of the community is so much indebted. It is only by experiments such as these, instituted by practical men, upon large breadths of land devoted specially to the purpose, that the value of the different manures can be ascertained.—The bone manure was pronounced to be the next in order, and, though it came something behind its rival in the effects produced by one experiment, it was generally believed that its strong enduring powers would come into active operation in due time, and that even before the end of harvest it would attain perhaps the first place. The value of the nitrate of soda, could not for the present be ascertained, as it had been applied about three weeks later than the others; but we hope to give some account of its progress in our report of the next meeting. The wood ashes came next to the bone-dust; and the malt screenings last of all.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—It is to be regretted that when animals, extraordinary in any particular, are mentioned in your paper, that the *breed* is not at the same time named. This is the case with regard to the 18lb. of butter a week cow, and the 59lbs. per quarter ewe, mentioned in your last number. I have frequently noticed and regretted this omission. It would be much more satisfactory to readers, if writers would be particular in this respect. I am, Sir, your most obedient servant,

P. C.

SIR,—For the satisfaction of your correspondent P. C., of last week, I beg to state that my ewe, which was 59lbs. per qr., (after being ill a long time) was bred from tups hired of Mr. Smith, of Charlbury, Oxfordshire, without a cross for more than thirty years.

I must also say, that if Mr. Smith, as leader, takes the right road, it is easy for those that breed from to follow.—Yours respectfully,

THOS. CARPENTER.

Hull Farm, Chipping Norton, Oxfordshire.

ON FOOT-ROT IN SHEEP.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—In your valuable paper of this week, to which I am a constant subscriber, is a nostrum for the *foot-rot* in sheep; now Sir, instead of going to the *chemist's shop* for ingredients, just go to the lime kiln for its cure.

First prepare a coop or stall, under cover, with dry sod, or other hard and even bottom; get stone lime fresh from the kiln, slake it and strew it in the stall in its powdered state, to the depth that a sheep's hough may be well immersed in it when standing; then take your foot-rot sheep, and pare the foot in the usual way; when done, put the sheep standing into the powdered lime, it will adhere to the bloody and raw foot, it will eat up all the bad flesh, and in a few times repeating complete a cure.

After they have stood an hour each time of paring they may be put into a plot where it is dry footing.

If you think this simple and cheap way of curing the foot-rot will be acceptable to your readers, you may do much good by inserting it in your useful columns.

I have thirty years experience and always found it complete a cure.

A CONSTANT READER AND SUSSEX
AGRICULTURIST.

P.S. After the lime is done with for the sheep, it will be good for manure; and another advantage, the lime is sure to adhere to the diseased part of the foot.

SIR,—In noticing the letter signed M. O. in the M. L. F. of the 27th inst., whose residence I know not, I beg to observe the agricultural public ought to be much obliged to any individual who will trouble himself to communicate that which he has found beneficial, and which he considers may be useful to farmers generally. I have frequently observed, that in giving recipes, they are given so inaccurately that they cannot be made up correctly even by skillful druggists, much less so by persons not at all skilled in the knowledge of medicine; hence so many failures from what have been considered *capital* receipts.

I am induced to make these observations in consequence of reading M. O.'s receipt for the *Foot-Rot* in your last week's paper. I agree with him, "Let your druggist make up the receipt," recollecting the farmer's favourite motto, "Live and let live." Now for the recipe: M. O. says, first take verdigris and alum, then *white mercury*. I ask, what is meant by "white mercury?" Then "vitriol;" again I ask, which "vitriol?" as there are vitriols of various hues, blue, white, and green, besides the oil of vitriol and spirits of the same; these explained will make his recipe intelligible, and I dare say a very good one. He directs to apply it with a piece of wood a little *hards* at the end; it is easy to imagine the "printer's devil" erred by putting an *stoo* much, and suppose he means the wood should be a little *hard* to apply the mixture to the foot with, many persons not being aware that by *hards* he means *tow*; in this locality *hards* is understood to mean *alum* as well as *tow*—hence mistakes are likely to occur. The public will be obliged to M. O. to amend his recipe, that it may become generally useful.

The Guinea Grain Wheat I know nothing of. Brown's Ten Rowed—I am this day carting it—looks well, and is heavy; and if M. O. will give me his address I will communicate to him the produce of 3½ acres which I shall soon thrash out.

ON BREEDING IN-AND-IN,
DRAINING MOSS, &c., &c.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—Will any of your talented correspondents inform me how the term, in-and-in, is applied, and in fact what is the meaning of it in breeding stock, as we on this side of the Channel know nothing of the term as applied?

In answer to your correspondent, relative to draining moss, with timber applied as soles for tiles where the moss is so soft that the slates sink unevenly in the bottom of the drain. I use larch fir cut into three-quarter inch boards as soles for tiles, but where the board is long and the moss very soft, I drive a small pile down in the centre of the drain, and lay a three-quarter inch board across the top of the pile, and nail it down to the pile; these I place every fourteen feet, or oftener, if the moss is very soft. Larch-fir I find stands longer in the ground than any other kind, and where the fall is not good the boards should be planed on the upper side, where the small particles of land or earth may not find any hold, or the least they may have may check the drains in a few years. If you think the remark worth while use it; if not, do not exclude more valuable matter from the columns of your valuable journal. I am, sir, yours,
Youghal, July 7. AN IRISHMAN.

ON UNDER-DRAINING.

SIR,—Seeing in your paper of the 27th a letter from a farmer north of the Tweed, relative to a difficulty he experiences in underdraining, I would recommend him to drive some small piles under the boards for them to rest on; and instead of tiles I should say make the whole drain with boards in the form of a triangle, which I think he will find, if made of alder or willow, will not cost him much more than 6d. per rod, and probably save him a long carriage for the tiles; and besides by using boards as long as he can get them, he will have less joints for the loose earth to run in; and I should also recommend him to have small gratings, such as the pieces of an old iron sieve, &c., to prevent rats getting in. Trusting this will in some measure meet the difficulties he encounters, I am, &c.,

NATIVE OF EAST KENT.

Sunday, July 19, 1840.

DRAINING MOSS LAND.

SIR,—If the writer of a letter, (which appeared in your *Express* of June 29), signed "A Farmer north of the Tweed," is wishing to have a practical illustration of the best system of draining moss land, I would earnestly recommend him to inspect parts of Chat Moss, near Manchester, which are now under cultivation, particularly the now reclaimed farms of Edward Baines, Esq., M.P., the Messrs. Evans and Co., and Thomsons; also it would be worth your correspondent's time, if he has a large tract of moss to cultivate, to inspect the drainage and other improvements now proceeding on White Moss, near Manchester, and not more than four miles from the town; the crops now growing on White Moss are the first ever attempted to be grown there, and both turnips and oats are looking inferior to no others I ever saw in the United Kingdom.

Should your correspondent take the advice here offered, and will direct a few lines for me, to be left at Ladyman's Hotel, Manchester, I should feel great pleasure in accompanying him to the different places named, as it might very well be done in one long day.

I am, Sir, yours respectfully,

A LANCASHIRE AGRICULTURIST, NEAR MANCHESTER.

REVIEWS.

THE READY RECKONER FOR WHEAT, BARLEY, AND OATS.

BY ROBERT WILLS, INSPECTOR OF CORN RETURNS,
CHICHESTER.

Hackman, Chichester, 1838.

It has seldom fallen in our way to notice a more useful publication than the above, or to see any work put forth in a manner so very unpretending, and free from ostentation. The author states neither the labour which the compilation has cost him, nor the praises and success he anticipates as being due to his exertions; he does not even recommend his work to the persons for whose use it is intended, nor calls for any reward but what the merit of the book may deserve. The title-page shows the contents of the matter, with the name and occupation of the author, and without a single observation of any kind, he leaves the work to sink or swim by its own merit, and in this respect it may serve as a model of title-pages and prefaces, the latter being most generally nothing more than a pompous oration of vanity and conceit, and of fulsome flattery well known to be false by the person who utters it. The neat little work contains the prices of wheat at the rate of 10*l.* 2*s.* 6*d.* to 20*l.* per load of five qrs., in quantity from four bushels to forty qrs.; the price increases by 2*s.* 6*d.* a load, and the quantity by four bushels until it exceeds twenty-five qrs., and then by one qr. to forty which terminates each calculation of a certain price. The prices of barley and oats are calculated from 15*s.* to 40*s.* a qr., and in quantity from 1 to 30 qrs. To farmers who have much grain to sell, to corn-factors, and to all persons who are engaged in business where the measures are used, the book is particularly adapted; the neat size and small bulk may be carried in a side pocket, so that in the counting-house and in the market, the usefulness is equal. The modesty of the author much enhances its merit.

"ILLUSTRATIONS OF THE BREED OF DOMESTIC ANIMALS OF THE BRITISH ISLANDS."—By DAVID LOW, Esq., Professor of Agriculture at Edinburgh, &c., &c.

The fourth part of this work has just appeared, containing the "Ox," and commences with the general history of the ox family, which is divided into three groups—the Bisonine, the Bubaline, and the Taurine. The European bison is now confined in small numbers to the forests of Sarmatia, where the remnant is specially protected by the Russian government, and a few are occasionally seen in the woods of the Caucasus, whence they extend to British India. The American bison forms numerous herds in the temperate regions of the northern continent, and are killed for the hides and flesh, and appear capable of being tamed and applied to domestic purposes. The musk ox abounds in a more northern latitude. The "bos grunniens" of the Tartars is placed in this group. Of the species of buffalo, the common kind abounds most in India, and is spread over Asia, and in many places in southern Europe, and a smaller species is found in Africa. The Taurine group is numerous, and comprehends the domesticated ox, with the various species. The author has given a very neat and concise history of the three groups; the size, habits, appearance, and character of the different animals; the dangerous encounters with them in the wild state, and the likelihood that exists

of their being tamed, and mixed by propagation with other breeds. Much research is displayed in collecting the materials; the account of the wild herds in Brazil is particularly interesting, and also of the African and Cape ox.

The plates of our native breeds are a Zetland cow, and one of the Kerry breed, very small animals, but much adapted to the situation; a bull of the Polled Angus breed, a valuable kind of animal, but much confined in extent, and apparently wearing out; and a bull and heifer of the Galloway breed, one of the most useful in this kingdom. Each plate is accompanied with an appropriate description, containing the peculiar habits of the animal, with the author's observations on their respective merits, the success of crosses, and the probability that exists of future improvement by crossing, or by breeding from the individual species. We could have wished something more had been said on the subject of the Galloway cattle, being the maternal origin of the short-horns, and possessing, with some trifling exceptions, the most complete carcass for the butcher that any breed can afford. The deep chest, round carcass, flat shoulder, and level back, short legs, and general symmetry, are not seen so much combined in any other animal. The rib, as the author observes, or back cut, is well known in Smithfield, and the meat brings a higher price, along with all Scotch cattle of that symmetry and size, a fact known to any butcher's boy, though it lately required a prize essay of ten pounds to tell us the contrary, in opposition to all experience. A coarseness attaches to the head, neck, and skin of the Galloway, which has been much removed by the eminent breeders mentioned by the author. We have much pleasure in bearing testimony to the increasing merits of this work, containing both ancient, modern, and practical information, for the collection and publication of which the author and publishers are equally entitled to our gratitude.

JONES AND HAN'S PATENT FOR AN IMPROVED PROCESS OF MANUFACTURING CIDER AND PERRY.—The manufacture of *sweet* cider and perry is an *art*—the mere act of grinding and expressing the juice from the apple or pear, and then putting it into casks, leaving Nature to finish the operation, has no title to be dignified by that term. In the latter case the delightful acido-saccharine juice is converted by the unchecked process of fermentation into an acrid, thin, austere liquor, which no one would touch but those accustomed to it, and it is only marketable among the labouring part of the community, fetching the lowest price, whilst the manufactured article is in fact a *wine*, and as such bears a proportionately higher value. In making use of this term "manufactured," we must not be understood to imply that any foreign or chemical ingredients whatever are introduced into the liquor, and if that is ever done, the patent which we are now about to describe in as few words as possible, is intended to accomplish the effect of keeping the sweets in the cider or perry by no other method than by a rapid process of filtration. The greater tendency of the juice of the apple or pear to run through the whole process of fermentation, above that of the grape in the southern parts of Europe, arises from an excessive quantity of a *ferment* imprisoned in the fruit, in proportion to the quantity of pure sugar in the juice, and a considerable portion of this *ferment* must be separated before its action becomes too violent. The mode of accomplishing this by the patentees is by double bags compressed into so small a space, and yet exposing a great filtering surface, that 120 of them will not occupy a space of more than four feet square. The mouths of these bags are fastened in their places by hollow plugs, which are easily removed, so that the bags can be taken out and replaced

with great rapidity when they become choked by the process of filtration; but this process would not be effectual without the use of an article which arrests all the floating feculencies that occasion the fretting and hissing, and yet adds neither taste or smell to the liquor passing through it, and this is merely well burnt and pure wood charcoal pulverized. The patent also includes a mill for grinding the fruit, different from anything hitherto in use either in Devonshire or Herefordshire. It is a roller converted into a rasp, by tools supplied with it, so that it can always be restored to its original roughness by any common labourer, when by use it is worn too smooth. We have ourselves tasted cider manufactured by this process, and can truly say that never before have we met with cider of so rich a body, so fine a flavour, and withal so rich and clear.—*Mechanic's Magazine.*

CALENDAR OF HORTICULTURE.

SEPTEMBER.

The directions which are given in periodicals, are too general; they remind me of those naturalists' calendars which mention the return and songs of birds, at certain dates and periods. All nature is subject to contingencies, and all directions must be received with some caution, and allowance for variations of latitude, climate, and exposure. In writing for the vicinity of London, we may be definite, but a kalendar which is to be read in Scotland or Ireland, as well as in Kent or Devonshire, must be subject to corrections. Perhaps Mr. Loudon's rule is as little exceptional as any that we can refer to:—it is the following.

"In general, other circumstances being alike, four days may be allowed for every degree, or every seventy miles north or south of London; in spring, operations may be commenced earlier in that proportion southward," (because it is presumed that the temperature is there more genial) "and later northwards" (obviously for the contrary reason). "But in the autumn the reverse, and operations deferred as we advance southward, and accelerated as we proceed to the north. In every case allowing a due weight to local circumstances."

Sufficiently contingent is all this, yet it may excupate a writer for any error he may commit which has its origin solely in difference of locality, and whose correction must depend upon the experience of the reader.

September, is the season, wherein every good gardener has it in his power to bring his ground into that condition of neatness and repose, which is so peculiarly grateful to the eye of many persons of excellent judgment. Vegetation has lost its active stimulus, yet it has not declined into complete torpor. Many crops have ceased to produce, others have ripened their seeds, and both should be removed to the manure or compost ground; after which every vacant spot should be dug or trenched, and if the land be of a stiff and binding texture, laid up in ridges.

Weeds grow with great rapidity at this season, for the sun retains much power, dews are strong, and in general a good deal of rain falls; therefore every opportunity should be seized to eradicate them by hand, hoe, and rake.

The summer sown cabbages will be advancing rapidly, therefore the ground should be kept quite clean, and its surface rather open.

Cape broccoli is coming into bearing, and as the white butterfly (*Pontia Brassicae*) is apt to make it foul with its numerous caterpillars, the plants

ought to be carefully examined, and the nuisance removed as soon as seen, otherwise this delicious vegetable will be injured in flavour and quality. The stalks and leaves of every plant, as soon as the head is cut, should be removed, and the ground made clean.

The spring succession broccoli, it is usual to remove, laying the plants down with the heads to the north against a sloping bank of earth, and covering the stems on the south side with mould nearly as high as the lowest leaves; this is a measure of precaution which we deprecate, though it appears to have been sanctioned by the late Mr. Knight. The roots are thereby disturbed, at a period when growth becomes torpid, whereas if the plants have been placed in a trench, the earth that lies in the ridges on each side, can be readily shovelled into the trench, and will thus protect the stems, without occasioning any disturbance of the fibres. The surface of the ground between the rows can then be cleaned and digged, which will give the plot a neat appearance.

Broccoli plants may yet be planted out from the seed, or nursery-beds.

Carrots sown in August, are to be weeded and thinned; a little more seed may be sown early in the month.

Cauliflower plants are pricked out at the close of the month, and protected under frames or glasses. Some persons place a few in small pots, and plunge them in a frame.

Cabbage plants should have the first remove at the commencement of the month; they gain strength and a stocky root, by placing them in a nursery bed of mellow unmanured loam.

Celery plants in the trenches, should be regularly moulded up; the earth ought to be chopped down from the edges when in a friable state, and made very fine. The plants should be confined by one hand, or by passing a string round them, while the fine earth is placed around each.

Endive may be transplanted two or three times.

Lettuces can be planted out; others placed in frames; and seed of the hardier cos sown twice in cold frames. Young lettuces now transplanted are greedily devoured by slugs; not only should the ground be strewn with air-slaked lime at night when the vermin is exposed, but slices of turnips ought to be laid along the rows as baits.

Mushroom beds may now be successfully made.

Welsh onions can still be sown to stand the winter.

Potatoes are suffering severely in many southern counties, from the long protracted drought, and as the herbage of the medium varieties was dying away early in August, and the tubers themselves became dead ripe, small, and very hard in texture, the rains must excite a secondary growth; it will therefore be prudent to dig such directly. Seed tubers must be very indifferent, and if Mr. Aitken's theory be correct, we shall have poor success next year, from sowing the over-matured potatoes of this dry season. We ought to raise fresh seedlings. These are generally more juicy than old store, and at this time a plantation of the second year from the seed, retains all its verdure, and is in full flower and fruit, while plants of the parent store are actually dried up, with every vestige of green completely destroyed: an example of this is before us.

FRUIT DEPARTMENT.

The currant and gooseberry bushes have been terribly infested by three broods of the caterpillar of saw-fly; (*larva of tenthrède*) hand picking has

been tried, and with some success; but in addition, (in order to destroy those, whose chrysalises may otherwise remain under ground, for the achievements of another year), we would recommend the trial of the following application, the receipt for which has just met our eye. "Boil some foxglove plants in an old copper, and water the trees overhead with the liquor through the nose of a watering pot. The effects will be instantaneous, and in a great measure it will prevent their appearance the following year."

This may, or may not be correct, but infusion of fox-glove is a poison; powdered hellebore is also recommended, and that is a still more active poison; nothing of the kind therefore is to be tried while fruit remains on the trees, but after it is gathered, experiments of the kind are perfectly justifiable.

Strawberries of every kind may be planted to the greatest advantage in September; the chief sorts are, 1st. *Keen's seedling*, for prolificity and early bearing, also for forcing in pots. 2. The old, or *Carolina pine*, for high and superior flavour. 3. The *large white*, later, and also of peculiar and milky flavour. 4. *Knight's Elton*. The last comes into season when all the others are gone, and it possesses a delicious acidity. In making the beds, trench the ground two feet deep, and enrich it as for asparagus, particularly at bottom; let the loam at top be light and mellow, not very rich with manure; and plant the finest and best rooted runners of the season in rows, either single along the borders, or in beds two feet apart; the plants may stand from six to nine inches asunder; then water freely. Keen approves of fresh dung for manuring the land, in preference to spit-dung.

For *old plantations*, Keen says that he always finds that to dig between the rows in autumn, "refreshes the plants materially."

If *raspberry plants* have not been cleared from old wood, and all that is superfluous of the new, these regulations should not be longer neglected.

Gather fruit as it ripens. It will not be amiss to cut away all the wood that has borne peaches and nectarines; clear back to the lowest shoots, that were selected at the *spring regulation for successional bearers*. Those shoots will ripen their wood more perfectly, if the sun and air have the freest access to them. After this dig the borders lightly, and leave them in the neatest order.

The *forcing departments* require much attention. *Pines* are in full bearing, and *successions* grow rapidly. The best soil for re-potting is a mixture of two parts mellow, friable, turfy loam, mixed up about a month before it is used with one-third of deer's dung, collected by the hand from the park, and laid in a heap to heat and break up for a few weeks. Sheep manure treated in the same way is next to it in value.

Vines under glass, the crop of which is gathered, should be more and more inured to air, but we believe that there is no necessity to remove the lights or withdraw the rods. Many gardeners keep plants all the winter in vineries, which would perish if fully exposed, yet the vines do well, and bear abundant crops yearly. Facts are more to the purpose than assertions, and, with the vine, habit is almost every thing.

FLOWER GARDEN.

Annual flower seeds, as of *clarkias*, *collinsia*, *schizanthus*, *mignonette*, *petunia*, and indeed of most of the same hardy plants, may be sown in

pots. These can be preserved in a warm and dry greenhouse all winter, but if in damp situations, all must perish.

Carnation and *pink layers*, and pipings of the latter, if well rooted, may be potted off, or placed in parterre where they are to flower. All the *dianthus* tribe like chalk, and a little of any calcareous substance, finely powdered, should be blended with the soil.

Chinese Chrysanthemums, if re-potted, will require the soil to be very rich, to bring them forward as rapidly as possible. *Verbenas* of several kinds should be potted; they furnish runners that root at every joint, if pegged down either in the soil, or into small pots of sandy loam.

Slips of *petunias*, *salvias*, *calceotarias*, of the shrubby varieties, &c., inserted in sandy earth, in a frame, will root freely, and may, by a little covering in cold weather, be safely preserved during winter. The horse shoe pelargonium can also be raised by slips placed in a pot of sandy earth, but this and the variegated scarlet and pink-flowered must be kept in a dry house.

DAHLIAS will be in perfection, we say nothing of this flower, except to caution any amateur against the vain attempt to produce a real blue flower by chemical agents; if such could act, it would only be upon the tubers through the medium of the soil, not at all upon the seeds. Therefore, if a blue could be obtained once, to insure perpetuity, even by cuttings, the same staple soil and the same agent, both identical to the utmost degree of minuteness, must be employed; and as this would be utterly impossible, no reliance whatever could be placed upon plants, for which, perhaps, an enormous price would be asked.

Dahlias are beautifully and effectively displayed against an open trellis.

Greenhouse plants that have been in the open ground must be taken up soon after the middle of September, and planted in pots of appropriate soil. They must be moderately watered, and placed in a close frame or house, till they make some fresh roots, and then have air allowed in gradually increased quantity. A little timely thought and precaution will render a plant handsome through the winter, which, if treated hastily, would lose its foliage and become a deformity.

Young geraniums raised from cuttings may be fully rooted; pot such off into small pots of leaf mould or heath soils, and reduced turfy loam. The old stock plants which have furnished the cuttings will have shown fresh signs of growth; then, and not till then, however small the developments, they should be turned out of the pots, and the old soil carefully removed, leaving as much about the centre as will suffice to preserve the new-made roots. The old wandering roots should then be pruned away, and the plants placed in much smaller pots of loam, with one-third of good leaf-mould.

The rationale of this process is, to preserve the life of the plant without stimulating it, and to induce it to produce abundance of fibres, which in the spring, when placed in richer soil, will promote a fine head furnished with large and rich foliage. During the torpid season a poor loamy soil tends to preserve the plant from dampness and decay, for it is not subject to that decomposition which all manuring substances are. Decayed turf and the earth produced from couch-grass roots, furnish the best loam for greenhouse plants.

EAST-RIDING (YORKSHIRE) AGRICULTURAL SOCIETY.

On Wednesday, the 29th July last, the annual show of cattle of this Association was held at Beverley, in two fields on the York road, belonging to Mr. Skelton, of the Rose and Crown—the usual place of meeting.

It was announced that the show fields would be ready for the inspection of non-members at 12 o'clock, on payment of 2s. each.

Inside the gate the fields were admirably laid out for the purposes of a shew, and were amply provided with pens and paddocks for the sheep and cattle, besides a kind of platform raised some distance from the ground, which overlooked the stock exhibited, for the use of the spectators. There was a fence all round the enclosure for the animals, for the purpose of excluding all intruders, so that the most perfect order and regularity were maintained throughout. The excellent secretary of the association, Mr. J. Boyes, was on the ground all day, and performed his part of the day's business to the satisfaction of every one. The shew altogether was an excellent one—and such as is calculated to add to the many laurels which the skilful and industrious farmers of the East-Riding have already obtained. The exhibition of horses and sheep was the subject of general admiration—particularly that of the former. There were four yearling colts by Revolution exhibited, which were much admired for their symmetry and colour. Six colt foals and two fillies by Mercury were also shown and attracted crowds of admirers. We observed three or four very fine unbroke stallion colts, a variety of yearling coaching geldings, and several coaching and hunting colts, three years old. In the extra stock Mr. Wm. Laybourn, Huggate, exhibited a beautiful chestnut stallion colt, by Fire-away, dam by Richmond, foaled May 14, 1839. This noble animal, impatient of restraint, stamped and pranced upon the ground at times, during which his beautiful figure was seen to great advantage. There was a superior brown yearling stallion exhibited by Mr. Hardie, of Seaton. Here also we found an excellent horse belonging to Mr. Moor, of Burn-butts, it is five years old, is a dark chestnut by Graysales, and is fitted to be either a hackney or a roadster. One very beautiful and powerful grey cart horse was shewn by Mr. Johnston, of Frodingham-bridge—it is seven years old. Mr. Jordison, of Lockington, exhibited a well-proportioned four years old horse by Napoleon-le-Grand. A very pretty bay mare four years old, by Belshazzar, was shown by Mr. Swaddle, of Killingraves. In a pen among the extra stock were exhibited several superior pure-bred Leicester sheep, which are to be sold soon by Mr. Campbell, and which are the property of Mr. Edwards, of Market Weighton. The selection of cart mares was good, as also that of mares for agricultural purposes. No less than thirteen road mares were exhibited. There was also a variety of roadster mares with foal, hunting mares, and coaching mares. The shew of rams and ewes attracted notice, and was much admired. The exhibition of bulls was good. The oxen exhibited were few in number, but of great size and fine stature. The pigs were not reckoned so superior, but one or two of those exhibited were highly approved of. The shew of implements was not so large, we think, as it was last year, but several very interesting agricultural machines were upon

the ground. Mr. Croskill, of Beverley, as usual, exhibited several, and carried off a prize. Mr. Robinson, Halsham, exhibited a new machine for dressing corn; Mr. John Robinson, of Brandes-burton, sole inventor, showed two or three horse thrashing machines; one of them will thrash from fifteen to twenty-five qrs. of wheat per day, and from twenty-five to fifty qrs. of oats per day. The last-mentioned machine has been extensively patronised by gentlemen who have found it to work well. Messrs. Gardners, of Banbury, exhibited a patent turnip cutting machine, also several improved thrashing machines. Mr. Dale, of Bridlington, showed a curious machine for blowing corn after it is dressed. A new dressing machine was exhibited by Mr. John Dry, corn dressing machine maker, Market Place, Beverley. Mr. Dry has invented this machine on a principle far superior to the old system, being more durable, simple in its construction, and less liable to get out of repair. It is no larger than the common dressing machine, but so constructed as to allow the riddles to be one foot six inches long, by two feet wide. This machine works at a more rapid rate than any machine heretofore invented. It has been tried by Mr. Hotham, of Lund, who highly recommends it.

THE JUDGES.

The names of the gentlemen who performed the difficult duties of judges on this interesting occasion are:—

FOR HORSES:—

Thomas Brooks, Esq., Crosby, Calstow; John Thistlewood, Esq., Lambcroft, Louth; Richard Nainby, Esq., Barneby-le-Beck, Grimsby.

FOR CATTLE AND PIGS:—

William Torr, Jun. Esq., Riby, Grimsby; Thos. Crofton, Esq., Holywell, Durham; Philip Skipworth, Esq., Aylesby, Grimsby.

FOR SHEEP:—

John Rob, Esq., Thorpe Fields, Thirsk; Thos. Short, Esq., Martin, Bawtry; William Henlock, Esq., Green Hamerton, Boro' Bridge.

We understand that 281 members were admitted into the shew ground, whose subscriptions amounted to 141.1s.; and that 1948 non-members were admitted by which was realized the handsome sum of 194.6s.; total, 208l.7s.; No. of persons admitted into the fields, 2224.

By about three o'clock the judges had finished their important duties; at a quarter to four, the door leading to

THE DINING HALL

was thrown open and the company admitted. At a little after four o'clock the chair was taken by Lord Hotham, (an admirable chairman) who was supported on the right by Mr. Crofton, Mr. Skipworth, Mr. Torr, Mr. Turton, &c., and on the left by Sir Thomas Legard, the Mayor of Beverley, Capt. Hotham, &c., &c. The vice-chair was occupied by J. — Pease, Esq., in the absence of the Vice-President of the association. Grace was said and thanks returned by the Rev. S. Creyke. About 700 gentlemen sat down to dinner. The cloth having been removed the toasts were proceeded with.

The following toasts were first given:—

"The Queen," three times three. (National anthem.)

"Prince Albert," three times three.

"The Queen Dowager and the rest of the Royal Family," three times three. (Auld Lang Syne.)

The VICE PRESIDENT (Mr. Pease) proposed the health of the Archbishop and the Clergy of the diocese.

"The Archbishop and the Clergy of the diocese," three times three.

Rev. S. CREYKE returned thanks.

"The Army and Navy," three times three.

Mr. CARTER, R.N., returned thanks for the navy. Major HALLON returned thanks.

The CHAIRMAN—Gentlemen, it now becomes necessary for me to request your attention and your patience for a short time while I will call upon the Secretary to announce to you the list of awards which have been made to the labourers, &c., and after that the list of prizes which have been awarded to the different competitors at the shew held this day—and then read to you the report of the committee of the association (Applause.)

The following is a list of the Premiums and Sweepstakes:—

Labourers in Husbandry.

Foster, Charles, Bainton, 10 children, first premium.....	£ 4
Jessop, William, Meaux, 10 children, second premium.....	2

Servants in Husbandry. (Single Men.)

Gray, William, Skidby, 31 years, in three services, first premium.....	3
Frier, Matthew, Bielby, 28 years with Mr. Fentiman, Bielby, second premium.....	2

Female Servants in Farming Service, not living as Housekeepers.

Bointon, Margaret, Beverley Parks, 17 years in two services, first premium.....	2
---	---

Labourers in Husbandry who have worked the longest time upon one or more farms, &c.

Needham, Joseph, Hatfield, 46 years, 8 months, Mr. Tanton, first premium.....	3
Wiles, William, North Dalton, 44 years, one farm, belonging to Mr. Dowker, second premium.....	1
Lamb, William, Kirby Grindalythe, 37 years on the farm occupied by Mr. Walker.....	5s.
Thurlow, Robert, Aike, 39 years, Mr. Robinson, Lockington Carr.....	5s.
Wood, Thomas, Eastburn, 33 years, Mr. Boyes, Eastburn.....	5s.
Newby, Stephen, Gardham, 39 years, Mr. Lee. Botham, John, Tibthorpe, 34 years on the farm occupied by Mr. Piercy.....	5s.
Jessop, William, Meaux, 32 years, with Mr. Wise, Meaux.....	5s.

The Committee awarded 5s. each to those labourers who have worked above 30 years on one or more farms.

Labourers in Husbandry not occupying more than two acres of land, &c. (Given by W. D. T. Dersberry, Esq.)

Nicholson, John, Ganstead, 11 children, (no relief,) first premium.....	3
Stephenson, William, Preston, 16 children, 8 arrived at manhood, received about 4l. in parish relief, second premium.....	2

Shepherds, (annual servants.)

For rearing lambs from a flock exceeding 200 ewes. In this class the first prize of 3l. was awarded to John Wood, Mr. G Simpson, Hunmanby Field, who had 237 ewes, from which he had on the 1st of June, 373 lambs, no ewes lost. The second premium of 1l. was adjudged to William

Roe, Mr. J. Beal, Kilnwick Percy, who had 341 ewes, from which on the 1st of June, he had 418 lambs, no ewes lost.

Shepherds, (annual servants.)

For rearing lambs from a flock exceeding 100 and not exceeding 200 ewes. The first prize of 2l. was given to David Goodhill, Mr. Thomas Sample, Bishop Burton, who had 139 ewes, from which on the 1st of June, he had 216 lambs, no ewes lost. The second prize of 1l. was adjudged to Jonathan Harrison, Mr. Johnson, Riplingham Grange, who had 157 ewes, from which, on June 1st he had 219 lambs, two ewes died.

Shepherds or other persons.

For rearing lambs from a flock of 100, and not exceeding 150 ewes. The first prize of 2l. in this class was given to William Taylor, Mr. Thomas Harrison, Leven, who had 125 ewes, from which on 1st June, he had 224 lambs. The second of 1l. was adjudged to Robert Nettleton, Mr. John Harland, Barmston, who had 100 ewes, from which on the 1st of June, he had 173 lambs.

Shepherds, or other persons.

For rearing lambs from a flock exceeding 40 and not exceeding 100 ewes. In this class the first premium of 2l. was adjudged to William Brown, Mr. Richard Chapman, Brandesburton, who had 65 ewes, from which, on 1st June, he had 122 lambs. The second prize of 1l. was given to Thomas Hopper, Wetwang, who had 56 ewes, from which, on 1st June, he had 95 lambs.

Shepherds for service.

Lakes, Matthew, Mr. Champney, Halsam, 38 years and 8 months, on the farm occupied by Mr. Champney, equal with next.....	2
Reaston Richard, 38 years and 8 months with Mr. John Simpson, Hunmanby.....	2

Bulls of any age, from any part of the Kingdom. Cup given by H. Broadley, Esq., M. P.: value 10l.

Botterill, Mr. John, Easthorpe (11 competitors). Cup

Bulls not exceeding 30 months of age.

Bell, Mr. Beverley Parks, (6 competitors)... 7

Yearling Bulls.

Gofton, Mr. T., Thirleby, (6 competitors)... 3

Yearling Bulls, (given by Mr. R. Iveson, Nuthill, near Hedon.)

Swaddle, Mr. John, Killinggraves, (3 competitors)... 3

Fat Beast, bred in the district.

Collins Mr., Dantborpe, (2 competitors.) 3

Two Steers bred by the Exhibitor, between one and two years old, 3l.—No competition.

Cows of any age in milk or calf.

Thompson, Mr. James, Beverley, (14 competitors)... 4

A cow exhibited by Mr. Simeon Webster was very good, and the judges had great difficulty in coming to a decision which animal was entitled to the prize.

Heifers in calf, above two and under three years old. Swaddle, Mr. John, Killinggraves, (no competition)... 3

Heifers in calf, above two and under three years old, bred by and bona fide the property of the shower.

Moore, Mr. Ralph, Brandesburton, first premium..... 3

Do., Do., second premium..... 1

Mr. Swaddle having got the prize in the last class could not compete in this class.

<i>Pair of Heifers, under two years old, bred by the Exhibitor.</i>		£
Watson, Mr. Charles, Seaton Ross, first premium.....	2	
Mathison Mr., Beverley Parks, second premium, (4 competitors).....	1	
<i>Five Tups for farming purposes, sole property of the Exhibitor.</i>		
Borton, Mr. John, Habton, near Malton, (6 competitors).....	12	
<i>Five shearling Tups.</i>		
Leighton, Mr. George, Osgodby, (3 competitors).....	7	
Mr. Borton was not eligible in this class, having obtained the prize in the last class.		
<i>Twenty Wether Shearlings. Silver Cup, given by Lord Hotham, M.P., value 10l. 10s., with a Sweepstakes of 1l. each. Second best 5l. Third, (given by Mr. George Piercy, of Kirkburn), 3l.</i>		
Foster, Mr. John, Southburn, first premium. Cup and Sweepstakes.		
Almack, Mr. Thomas, Bishop Burton, second premium	5	
Jackson, Mr. Thomas, Routh, third premium, (7 competitors—14 entries).....	3	
<i>Five Shearling Gimmers. Silver Cup, given by James Walker, Esq., of Sand Hutton, value 10l. 10s., with a Sweepstakes of 1l. each, for the best Pen. Second 5l.</i>		
Hill, Mr. Henry, Sledmere Field, first premium, Cup and Sweepstakes.		
Almack, Mr. Bishop, Burton, second premium, (11 competitors—20 entries).....	5	
Nine Gentlemen entered who declined to compete.		
<i>Five Breeding Ewes and Lambs.</i>		
Iveson, Mr. Richard, Nuthill, near Hedon, first premium.....	3	
Almack, Mr. John, Leckonfield, second premium, (5 comp.).....	1	
<i>Wool.</i>		
Three fleeces of Hog Wool, (offered by E. W. Smith, Esq., of Routh).....	2	
Hill, Mr. Henry, Sledmere Field, (4 comp.).....		
<i>Stallions for Coach Horses.</i>		
Sheffield, Mr. George, Walkington, (18 comp.).....	5	
<i>Stallions for Hunters.</i>		
Reynard, E.H. Esq., Sunderlandwick, (3 comp.).....	5	
<i>Stallions for Roadsters.</i>		
Jefferson, Mr. Market, Weighton, (5 comp.).....	5	
<i>Stallions for Cart Horses.</i>		
Broadbent, Mr. Jonathan, Hull Bank, (4 comp.).....	5	
<i>Coaching Mares with a Foal.</i>		
Watson, Mr. John, Risby, (14 comp.).....	5	
<i>Coaching Mares.</i>		
Fisher, Mr. Robert, Leckonfield, (8 comp.)...	2	
<i>Hunting Mares with a Foal.</i>		
Clarke, T., Esq., Knedlington, (8 comp.).....	5	
<i>Hunting Mares.</i>		
Holiday, Mr. John, Wetwang, (4 comp.).....	2	
<i>Roadster Mares, with a Foal.</i>		
Nicholson, Mr. J., Watton Grange, (8 comp.)..	5	
<i>Roadster Mares.</i>		
Binnington, Mr. Thomas, North Dalton, (17 comp.)	2	
<i>Pair of Mares for Agricultural purposes.</i>		
Staveley, Mr. Isaac, Tibthorpe Wold, (3 comp.).....	4	
<i>Cart Mares.</i>		£
Staveley, Mr. Isaac, Tibthorpe Wold, (10 comp.).....	2	
<i>Three Years Old Coaching Geldings.</i>		
Northgraves, Mr. William, Cottingham, (8 comp.).....	3	
<i>Two years Old Coaching Geldings.</i>		
Johnson, Mr., Bringham, (10 comp.).....	3	
<i>Yearling Coaching Geldings.</i>		
Holby, Mr. Thomas, Rotsea, (7 comp.).....	2	
<i>Three Years Old Coaching Fillies.</i>		
Birbeck, Mr. Henry, Scorb'ro', (12 comp.)....	3	
<i>Three Years Old Hunting Geldings.</i>		
Dalby, Mr. John, Corps Landing, (7 comp.)..	3	
<i>Yearling Colts by Revolution.</i>		
Drinkrow, Mr. John, Driffield, (4 comp.)....	6	
<i>Yearling Fillies, by Revolution.—No entry.</i>		
<i>Colt Foals, by Mercury.</i>		
Ransom, Mr., Wawne, (7 comp.)	5	
<i>Filly Foals by Mercury.</i>		
Hopkinson, Mr., Wawne, (2 comp.).....	3	
<i>Boars, Large Breed.</i>		
Petch, Mr. Robert, Southcoats, first premium..	2	
Moment, Mr. William, Walkington, second premium, (6 comp.).....	1	
<i>Boars, Small Breed.</i>		
Naylor, Mr. James, Grovehill, first premium..	2	
Smith, E. W. Esq., Routh, second premium, (2 comp.).....	1	
<i>Sows, Large Breed.</i>		
Fish, Mr. John, Preston, first premium.....	2	
Hall, James, Esq., Scorb'ro', second premium, (8 comp.).....	1	
<i>Sows, Small Breed.</i>		
Stephenson, Mr. G., Beverley, first premium..	2	
Hall, James Esq., Scorb'ro', second premium, (3 comp.)	1	
<i>Newest Agricultural Implements, not exceeding 5l.</i>		
Dry, Mr. John, Beverley—New Dressing Machine, invented by him.....	2	
Grayburn, R. S., Esq., Wootton House, near Barrow, for a Turnip Horse Hoe—a medal, value . 1		
Crosskill, Mr. William, for a Corn Rake and a Liquid Manure Cart	3	
<i>Extra Stock.</i>		
To Mrs. Edwards, of Market Weighton, for five Shearling Tups, to Mr. John Botterill, of Easthorpe, for two Cows, and to the Rev. L. Dennis, for a Hunting Mare, a silver medal each was awarded.		
<i>Sweepstakes of 10s. each.</i>		
Bulla.—Bosville, A., Esq., Thorpe (5 subscribers). Yearling Bulls (20s. each).—No competition.		
Cows.—Webster, Mr. Simeon, Aughton, (5 sub.)		
Two Year Old Heifers.—No competition.		
Yearling Heifers.—No competition.		
Fat Steers.—No entry.		
Aged Tups.—No competition.		
Shearling Tups.—Borton, Mr. John, Habton, near Malton, (2 subs.)		
Five Wethers.—No entry.		
Five Suckling Ewes.—No entry.		
Fat Wether, Ewe, or Gimmer.—Foster, Mr. Rich., Southburn, (2 subs.)		
Stallions for Coach Horses.—Bateson, Mr. Leonard, Bringham, (2 subs.)		
Stallions for Hunters.—No entry.		
Stallions for Roadsters.—Jefferson, Mr., Market Weighton, (2 subs.)		

Stallions for Cart Horses.—No competition.
 Yearling Stallion Coaching Colts.—Watson, Mr. John, Risby, (3 subs.)
 Coaching Mares.—Windass, Mr. Thomas, Beverley Parks (4 subs.)
 Hunting Mares.—No entry.
 Roadster Mares.—No competition.
 Cart Mares.—No entry.
 Three Years Old Coaching Colts.—No entry.
 Two Years Old Coaching Colts.—No competition.
 Three Years Old Coaching Fillies.—Bateson, Mr. Leonard, Brigham (3 subs.)
 Two Years Old Coaching Fillies.—Shilton, Mr. John, Nunkeeling, (5 subs.)
 Three Years Old Hunting Colts.—Knapton, Mr., Dunnington (2 subs.)
 Two Years Old Hunting Colt.—Brandham, Mr. Wm., Dringhoe, (2 subs.)
 Yearling Coaching Geldings.—Bilton, Mr. William, Rise (2 subs.)
 Two Years Old Stallion Hunting Colts.—No competition.
 Boars, Large Breed.—No competition.
 Boars, Small Breed.—No entry.
 Sows, Large Breed.—Bennett, Messrs. G. and E., Hornsea, (2 subs.)
 Sows, Small Breed.—No entry.

The successful labourers in husbandry, &c., were here called up and addressed by the CHAIRMAN.—The duty now devolves upon me to address a few words, and a very few words, not only to those whose names have been called already, and who have now been brought forward in the presence of this large assembly to receive the rewards which the committee have had it in their power to announce to them for the encouragement of good conduct and of good services rendered by them to their families and masters, in the various situations in which they have been placed. (*Cheers*). Gentlemen, (addressing the successful competitors) to some of you rewards have been given for having brought up the largest families without having had recourse to parish relief—to others rewards have been given for having continued the greatest number of years in one service—to another party rewards have been given for having reared the greatest number of lambs—a great proof of the attention displayed by you in the performance of your duties. (*Cheers*). Rewards were also given for services of other descriptions, but which it is not in my power to particularize, as I am speaking only from a recollection of the awards for different kinds of labourers which have been read over by our secretary. The association, I have great pleasure in being able to say, is ready to offer similar rewards for the same services. The Chairman in the course of some further remarks, observed that he believed from their conduct the successful competitors were well educated, and he hoped they would also educate in the same way their children.

The CHAIRMAN again rose and said—I must further request your attention whilst the report of the committee is read by Mr. Smith,

Mr. SMITH then read the report of the committee. It congratulated the society on the present successful appearances which it presented, and called upon the members and friends of the association for renewed exertion.

The CHAIRMAN—I now return to the performance of that part of my duty, as your chairman, which has been necessarily interrupted by the statements which you have just heard made to you by the secretary, and also by my friend Mr. Smith,

at the other end of the room—an interruption which was only further accompanied by a second interruption on my part, which however, I hope you will have excused—inasmuch as it had for its object, however inadvertently I may have done so, the impressing upon the minds of those who have now been called before you, and it may be upon others, that we who happen to be placed in a position of life above them, are not inattentive to their necessities, and are not otherwise than anxious for their welfare (*Applause*). The association are most anxious that they should continue to exhibit the same kind of conduct, the pursuance of which has placed them in that proud situation, in respect of which they have been already brought before this assembly. Gentlemen, I would now beg to give to you as the next toast “Success to the Agricultural Association of this Riding”—(*cheers*)—a toast which I should not have the slightest difficulty in proposing to you were it not that I know that you will expect that a toast of this nature should be accompanied by observations from me, and that you will have formed expectations that a toast of this nature should be accompanied with the requisite number of other toasts, but which I know I am perfectly unable to fulfil (*no, no*). It is therefore this feeling which creates an embarrassment in my mind in proposing the next toast. Gentlemen, I desire earnestly that you should not only concur with me in drinking success to your agricultural association, but that you should endeavour to give practical effect to that success by every means and in every manner in which it lays in your power to do so. I would gladly suppose that there can be no individuals present who require to have demonstrated to them the advantages of such societies as the present. But should any such be present in this assembly, I would only desire them to recollect in the first place what was the agricultural situation of the East Riding of York about forty years or rather more than forty years ago (*cheers*). If every one had been contented to go on in the same path which he had heretofore pursued—if every one had fancied that the system they themselves were pursuing was one which admitted of no improvements, how could it have been possible that we should have the face of the country so entirely altered as it has been during the period to which I have alluded? I know, gentlemen, that it may be said that the improvement of the face of the country took place under circumstances widely different from those of the present time—that the country was at that time engaged in a war the effect of which was to enhance the price of every kind of provision, and the effect of which was to induce parties to go into paths different from those which they had hitherto pursued. But, gentlemen, let it not be said that because those who have gone before us have so far changed the face of the country—do not let us suppose that we are in a state admitting of no further improvement (*hear hear*). Gentlemen, we can on no ground whatever come to such a conclusion. But supposing that were the case, let us just look around us and see what is doing. Let us see if the other parts of the country are encouraging associations like the present one. The country was giving such societies encouragement, and I believe that the result of such associations will be to effect the desideratum of agriculture, namely to grow the greatest quantity of produce at the smallest expense; and I desire you to consider what would be the consequences of our standing still, while all

the neighbouring localities were encouraging the formation and continuation of associations like this—to effect, and they would effect improvement in that description of business, namely, agriculture, in which you are all concerned (*Cheers*). Gentlemen, it cannot be unknown to you, and if it is unknown to any body he cannot lose too little time in satisfying himself of the belief of the truth of that of which I have myself no doubt, namely, that the soil of this country is capable of being brought to a higher state of cultivation than that at which it has arrived—and it is in consequence of that that I desire you to unite with me in drinking to the success of this association. The science of chemistry as connected with agriculture, was only very imperfectly and inadequately understood—(*hear hear*):—and I want to know if any—perhaps a few persons may have talents so to do—but it is possible that the mass of those I now see before me can be studying in their houses with a view of acquiring a knowledge of that which is the best method of applying the science of chemistry to agriculture. I will not dilate on the various experiments which have been made in the practical application of our land by the introduction of manure different from that formerly in use. But it is the fact that from the use of manures different from those in common use great advantages would be gained. How far it may be possible to realize that I will not say, which my honourable friend (Sir Thomas Legard) on my left hand held out to those whom he has so lately addressed at Burlington. I will not with great confidence hold up my hand to say what he did; but if it be true that a man may carry in his waistcoat pocket as much manure as may manure an acre, then the science would be worth contending for (*Applause*). My object, gentlemen, in desiring you to promote the success of this association, is that you may not mistake that precise article to which my honourable friend alluded to—but I will not place myself in the same situation of finding the truth of what was stated by one who said that he could carry in one of his waistcoat pockets as much manure as was sufficient for the purposes of an acre of land. In reply to this it may be said that the other pocket would contain all the produce of the manure, which the first-mentioned pocket contained (*Applause and laughter*). That, gentlemen, is another reason why I most earnestly beg of you to promote the success of this institution. Let me ask any of you who have been in the show-field in the course of the day,—and I presume all of you have attended—I might ask, though the quantity of the stock exhibited may not have come up to the expectations of you all, whether there has not been a show in that field amply sufficient to gladden the hearts of all engaged in the prosperity of agriculture (*Cheers*)? Then there is another reason why I would most earnestly appeal to you all to give attention to promote the interests of the society of which I am a sincere but inefficient advocate. I ask you not to let the association suffer in consequence of the small number at the show from the badness of the day—or from any trivial cause of absence—or because a friend of yours will not consent to come to Beverley and make it a party of pleasure (*Applause*). I invite you on the other hand to become members of the association (*Applause*). I wish you to identify yourselves with the prosperity of the association—to identify yourselves with the soundness of the society, to see that the number of its members is large—and that its funds are ample—and that it is able to give

prizes of that value and to that extent which may make it worth while for persons to become competitors for them (*Applause*). Gentlemen, it is on these various grounds that I trust the proceedings of this day may bring to our association a large increase of members, and from the description of persons I have the pleasure of seeing around me—if an increase of numbers is brought there will along with it be brought an increase of respectability (*Applause*). Gentlemen, why should any of you not join us who have, as you all know, a most effective committee—a body of gentlemen who, to great personal inconvenience and with much toil and labour, conduct the business of the association. Some of the members of the committee belong to the same rank in life to which I belong—others again in the rank of most of you, respectable yeoman—farmers are everywhere represented in the committee, and in such a way as to satisfy you that due justice will be done to you all—you have the most effective secretary (*Applause*). There can be no doubt on that subject. You have, therefore, every inducement to join the association. You certainly have a very inefficient president (*No, no*). I am perfectly aware that in your president you have manifest inefficiency, but I trust that you will not let the association suffer in consequence of any want of those qualifications which you might have expected he would have displayed this day (*Cheers*). I hope on the other hand that you will all sink in your consideration the inefficiency of the president, who had put himself forward in a situation which he knew he was unable to fill. In conclusion the noble chairman called upon the company to pledge success to the society in a full bumper (*Great applause*).

“Speed the Plough”—*six times six*.

The CHAIRMAN—Gentlemen, the next toast will be proposed to you by Sir Thomas Legard, to whom I therefore request your attention (*Cheers*).

Sir T. D. LEGARD said—My Lord and Gentlemen, before proposing the toast that has been unexpectedly assigned to me, perhaps I may be allowed to remark, that it is no small gratification to me to be present at the opening of this large, and, as it promises to be, handsome structure; and that gratification is increased when I reflect, that of all the uses to which this room may hereafter be applied, none could have been more auspicious for its opening than a large agricultural dinner, at which all persons may assemble, free from the angry feelings of party strife and politics; having no object in view but to advance the interests of a peaceful calling—to encourage industry—to increase the productiveness of the soil—and so to spread smiling plenty throughout the land. But to proceed with the toast: many persons who are now here, may recollect, that at the great Yorkshire Agricultural Meeting, last year, held at Leeds, Mr. Beckett Denison, in proposing the toast now entrusted to me, drew a very animated picture of a half-bred hunter, and he endeavoured to impress upon the members of the association, the propriety of breeding from horses of that kind. Now, although in these times of Eglinton feats, and restored chivalry, any one chancing to see Mr. Beckett Denison, who is a tall fine manly person, and a noble specimen of the genus homo, mounted upon a powerful active half-bred hunter, and charging the fences in the rear of the grand stand at Doncaster, in pursuit of the ragged regiment of thimble riggers, as once upon a time took place; any one, I say, seeing two such specimens of man and horse, might for a moment be led away from his

better judgment, and be inclined to think it matters little how the animal is bred, so long as it is a good specimen of the kind; but I believe there is no greater fallacy than this; all the writers upon agriculture lay it down as a maxim of the first importance, that purity of pedigree should be preserved, at all events on the side of the male; and every practical farmer is aware of the danger and difficulty of crossing, and the endless confusion that arises when they begin from a half-bred sire; in fact, the very thing Mr. Denison would suggest, has been repeatedly tried by individuals, but never with any uniform success. A chance good hunter or two may have been produced, but nothing to the number of misshapen mongrels, whose want of pedigree and want of pace, have made them almost unsaleable, and certainly unrideable, for who would buy a hunter without a pedigree, or risk his neck over the Holderness clays on a horse that was short of breeding; but I feel that it is utterly useless to occupy your time in conflicting opinions so entirely at variance with your experience and wiser practice, for I feel satisfied that no theory about half-bred hunting stallions will ever make a revolution in your opinions; and I trust it will never go forth again, that in Yorkshire of all places in the world, the agricultural societies give a preference to the breeding of cocktails. It now only remains for me to give the toast, trusting that those gentlemen whose healths I have to propose, will enlarge upon those subjects for which they have been successful. I have the honour to give you—"The successful competitors."

"The health of the successful candidates."—*(Three times three.)*

The CHAIRMAN said, he would be happy to hear any of the successful candidates return thanks.

E. H. REYNARD, Esq., of Sunderlandwick, after being loudly called for, rose for the purpose of returning thanks on behalf of himself and of the other successful competitors. For the very flattering mark of their attention in singling him out from among the competitors of that day who had been successful, he returned them his most heartfelt thanks. If all the exhibitors of the day felt as happy as he did, the judges might go home feeling that they had given satisfaction. *(Laughter and cheers.)*

The CHAIRMAN—Gentlemen, I beg to announce to you that the next toast will be proposed by Mr. Edward Smith *(Applause.)*

Mr. SMITH proposed, in an excellent speech, the

health of the tenantry of the East Riding of Yorkshire. He dwelt upon the good character and industry of the yeomanry of the East Riding, and called loudly upon the landlords to support them in their exertions, by giving their countenance to such meetings as the present, which were of the highest importance, and by subscribing towards the funds of the association.

"The tenantry of the East Riding."—*(Four times four.)*

Mr. HILL returned thanks.

Mr. HILL, at the request of the Chairman, rose with very great pleasure to propose the health of those gentlemen who had so kindly undertaken to act as judges on this occasion. *(Cheers.)* And although he had not been fortunate enough to have produced stock there to-day, for which, in the opinion of those gentlemen, he was entitled to receive a prize, yet so confident was he, from the care and attention which those gentlemen displayed in looking at the stock which had been brought before them, as well as from the good judgment which those gentlemen are well known to possess—he believed that those candidates who, like himself, had been unsuccessful, would return home, convinced in their own minds, as he had been, that they had been fairly beaten; and that they will make exertions to bring forward stock next year, which might render them deserving of the prize which he hoped would be awarded to them. *(Loud cheers.)* He would not detain them longer, but beg them to rise and drink the health of the judges. *(Applause.)*

"The Judges." *(Five times five.)*

Mr. TORR, of Riby, Lincolnshire, one of the judges, returned thanks in a neat speech. The judges, after the reception which the toast had received, were amply compensated for any trouble they had been at in the course of the day's proceedings. He congratulated the members highly on the fineness of the stock of every description which had been shown in the yard that morning; and he was desirous to mention in particular the exhibition of horses and sheep—*(hear)*—such an exhibition of horses, he believed, if equalled, could not be surpassed by any local association in England. *(Applause.)*

The healths of the "President" and "Vice-Chairman and Committee" followed, shortly after which the Noble Lord left the chair. A merry party remained, and kept up the entertainment some time longer.

AGRICULTURAL REPORT.

GENERAL AGRICULTURAL REPORT FOR AUGUST.

Taken as a whole, this has proved the most auspicious and favourable month to the crops, as well as vegetation in general, we have had to record for a series of years past; while the prospect of our farmers has been decidedly improved in every point of view. From the 1st till about the 8th the greatest anxiety was manifested by all classes as to the appearance of the standing wheat, owing to the numerous misstatements which were put forth by speculators and others, and to accounts being received from the growers themselves of an opposite tendency. Throughout the western, southern, and midland districts, the wheats, upon poor soils, were re-

markably thin; while upon highly cultivated farms not the least complaint could possibly be made. In the northern counties, viz. Lincolnshire, Leicestershire, Northamptonshire, Yorkshire, &c., the crops of all descriptions of grain, but more particularly those of wheat and barley, were fine almost beyond recollection; indeed, we ourselves are called upon to admit that finer wheat than that we have seen growing in the vales of the neighbourhood of Spilsby we never witnessed, and that no just cause existed for the very melancholy reports which were observed in many contemporary prints. However, the true test to all this is thrashing, which has been carried on somewhat extensively—nearly 1,300 quarters of new wheat having appeared on sale at Mark-lane alone; and fair remunerative prices have been readily ob-

tained—those parcels of 59 to 60lbs. per bushel having realized 74s. to 78s.; those of 60½ to 63½lbs., 80s. to 84s. per quarter. Scarcely any barley has, as yet, been submitted to that process, but the yield is highly spoken of. With respect to this year's growth of wheat, we have come to this matured conclusion, viz., that it will come up to a fair average for the kingdom, and prove the finest as to quality ever gathered. Now we hold that *quantity without quality* is a great evil, and that a fair quantity, *with quality*, more than compensates for any slight deficiency which may be found to exist in the general yield. We may, possibly, be asked, whether or not there will be a sufficiency of wheat grown this year to meet every demand for home consumption? Our answer would be, that a slight importation of foreign, of superior quality, will be required. However, as it is fully anticipated that the duty will recede next week, either to 3s. 4d. or 2s. 8d. per quarter, the whole of the bonded stocks, amounting to upwards of 500,000 quarters, will be thrown upon the home market, and readily counterbalance any of the evils which may arise from limited supplies of English wheat. There is one subject to which we beg to direct the attention of our readers, we mean the fallacious idea which appears to be gaining ground of the prices of wheat, in the event of the whole of the warehoused quantities being released at a very low or nominal impost, suffering a rapid declension; but such cannot, even under those circumstances, be the case, as it is well known that the wheat in bond is chiefly from Danzig, Hamburg, and Riga, and of the best marks shipped from those ports; hence will always command high rates, even with a steady influx of that of home production. Notwithstanding the violent gales of wind and heavy rains which were experienced about the 18th, we are happy in being enabled to assert that the communications which have been transmitted to us, by our numerous farming correspondents, convey the pleasing intelligence that but trifling injury was sustained in any quarter; while, on the contrary, the greatest benefit was derived by the turnips—which had become sickly and yellow, from the absence of sufficient moisture. At least three-fourths of the wheat and barley have been already secured in favoured districts; while north of the Humber harvest has become general.

In the various markets of consumption held in our provincial districts in the course of the week, the supplies of English wheat have proved somewhat extensive, and of very superior quality. In barley a limited amount of business has been passing; but good sound oats have gone off briskly, at an enhancement of 6d. per quarter. Beans and peas have commanded little attention.

Throughout Scotland, copious showers of rain have fallen, which appear to have had a beneficial effect upon the crops: and the value of corn and pulse has declined materially.

From Ireland we have letters, stating that the harvest is proceeding rapidly, but the produce is expected to exhibit a comparative falling off, both as respects quantity and quality: still the quotations of corn have suffered a considerable depression.

In the north of England the hay harvest has been concluded, but the produce is not superabundant.

Store stock has been held at high rates, owing, possibly, in a great measure, to the prevailing epidemic having caused many severe and almost irreparable losses to our graziers.

The following is our monthly statement of the supplies and prices of fat stock exhibited and sold in Smithfield cattle market. The former have consisted of 14,222 beasts; 132,000 sheep and lambs; 994 calves; and 3,040 pigs; while the latter have ranged as follows:—

Beef, 3s. 2d. to 4s. 8d.; mutton, 3s. 4d. to 4s. 10d.; lamb, 5s. to 6s.; veal, 4s. to 5s. 2d.; and pork, 4s. to 4s. 10d. per 8lbs. to sink the offals. The primest beasts, sheep and lambs, have commanded a steady inquiry; but the inferior kinds, as also calves and pigs, have experienced a sluggish demand. There has been a general complaint amongst the salesmen of the stock coming to hand in very bad condition, arising not only from its half-fat state, but also the prevailing complaint before noticed.

A STATEMENT and COMPARISON of the SUPPLIES and PRICES of FAT STOCK, exhibited and sold in SMITHFIELD CATTLE MARKET, on Monday, August 26, 1839, and Monday, August 24, 1840.

THRASHING MACHINES, &c.

TO THE EDITOR OF THE FARMER'S MAGAZINE.

SIR,—May I beg to ask some of your numerous readers which of the many sorts of thrashing machines they would recommend to a person cultivating but ten or a dozen acres of corn a year? The flail I have a great objection to (and the machines at present in use in this county, Devon,) are all of three or four horse power, and the outlay quite out of proportion to a small farm. And also, if the same machine could not be constructed so as to grind barley for the pigs, and cut chaff, &c., for horses, and at an outlay sufficiently moderate to justify a small farmer in purchasing one? Having grown a quantity of buckwheat this year, I want to know the best way to make the most of it, and also the particulars how to cultivate the winter oat, how often they are to be cut, and the latest time to cut them, &c.

If you will allow me, through the medium of your journal, to obtain information on the above mentioned subjects you will oblige, Sir, your constant reader,]

Exeter, August 1st, 1840.

S. T.

TO THE EDITOR OF THE FARMER'S MAGAZINE.

SIR,—As your excellent Journal seems the best medium of procuring agricultural information of all descriptions, I shall feel much obliged as a young breeder of cattle, if some experienced person will inform me at what age heifers generally produce their broad or cow's teeth. I am sir, yours obediently,

YOUNG FARMER.

AGRICULTURAL INTELLIGENCE, FAIRS, &c.

IPSWICH LAMB FAIR.—On Saturday, Aug. 22, this annual mart was held at Handford Hall, when upwards of 110,000 sheep and lambs were penned. The good effects of the recent genial showers were apparent in the capital condition in which the animals came up to the field. Though the show was considered a good average one, and the buyers were comparatively scarce, yet the prices of lambs were high; business, however, on the first day was not so brisk as usual. On Monday the supply being thinner and the demand equal to that of Saturday, there was considerably more trade than has been remembered for many years on the second day. Both buyers and sellers seemed to come with the disposition and determination to deal, and consequently very many extensive sales were effected, prices being a shade higher than on the previous day. One of the principal growers informed us that he disposed of his flocks without much difficulty as soon as penned. Among the flocks sold were the following, belonging to the most eminent growers in the county:—Mr. Rist, of Foxhall, sold his ewe lambs at 30s., and wether lambs at 25s. Mr. Catlin, of Butley Abbey, sold his ewe lambs at 26s. Mr. Joseph Burrell, of Tuddenham, sold 800 half-bred shearing wethers and ewes, at from 36s. to 42s.; his down ewes at from 32s. to 42s., and his ewes and wether lambs at from 20s. to 24s. These were very large lots. Mr. Everitt sold his ewe lambs at 28s., and his wethers at 26s. Mr. T. Betts sold his fine flock of Norfolk ewe lambs at 40s. Mr. Calleeu, of Chillesford-lodge, sold his beautiful shearing ewes at 40s. Mr. Fyson, of Heigham, ewe lambs at 28s., and wether lambs at 25s. 9d. Mr. Kersey, ewe lambs at 21s. Mr. Edwards, down ewes 28s. Mr. Cutting, wether lambs at 22s. Mr. Garnham, of Rougham, wether lambs at 24s. 6d. Mr. Webb, (brother of the famous Mr. Jonas Webb, of Braham), down ewe lambs at 26s. Mr. George Gale, of Rushmere, ewe lambs at 25s., wether lambs at 24s., and the refuse at 19s. Mr. Roper, of Rougham, ewe lambs at 25s. 6d., and wether lambs at 23s. 6d. Mr. Webb, of Hinthlesham, ewe lambs (sold to Mr. T. Crisp, of Gedgrave) at 26s. Mr. Frost, of Witherstead, refuse lambs at 26s. In the beast department, there were several animals; but the quality of those exhibited was not such as to require any particular notice; and the trade was slack. There was a splendid show of horses; and very extensive stands of poney—this part of the fair received much attention, and a good deal of liveliness prevailed among the dealers. Messrs. Ransome, according to custom, showed an extensive lot of agricultural instruments, consisting of patent ploughs, chaff engines, &c. &c.; and we understand transacted a great deal of business. Messrs. Bond, Turner, and Hurwood, of St. Peter's foundry, also had an establishment of the same description on the ground, and we are happy to observe that these gentlemen appeared to be very busily engaged with a numerous body of friends.—*Ipswich Exp.*

LINCOLN MARKET, Wednesday, Aug. 12.—There was a fair supply of beasts to this day's market, of good quality, which experienced not so good sale as at previous markets; they were however nearly all sold at from 7s. to 7s. 6d. per stone. Of sheep there was rather a short supply; the sale brisk at from 6d. to 6½d.

MELROSE LAMB FAIR.—At this great lamb fair held this day (Wednesday) the supply of lambs, principally bred and half-bred, was fully greater than last year, the number being stated at about 70,000, and they were in general of excellent quality. Great numbers of buyers being in attendance, it was a capital market, and nearly all were disposed of, at prices much the same as at the recent lamb markets. Bred lambs brought from 20s. to 23s.; half-bred from 16s. to 20s.; Cheviot lambs, best, from 10s. to 12s., and inferior lower in proportion.

SAXMUNDHAM LAMB FAIR.—We have the pleasure to state that the quantity of stock and lambs at this fair shewed an increase. There were from ten to twelve thousand penned, which met a ready sale at liberal prices. Nearly the whole were sold. The com-

pany was numerous: amongst whom were Sir Charles Blois, Bart., the Hon. Mr. Vanneck, Mr. Arcedeckne, Mr. Bales, Mr. Barthrop, &c., and many of the principal dealers from this county, and Essex and Norfolk. The best possible arrangements were made throughout.

FLOCK SALE.—At the sale by auction of South-downs, of Thomas White, Esq., at the Friday Wood Farm, in the parish of Beresford, near Colchester, held last Tuesday, August 18th, by Mr. J. G. Fenn, the following prices were realised:

	s.	d.	s.	d.	s.	d.
Pure Southdown Stock Ewes	37	6 to 26	6	30	0	
Crone Ewes	21	6	12	6	19	6
Wether Lambs	29	0	23	0	26	3
Ewe ditto	25	0	16	0	21	6
One and Two-shear Tups	126	0	42	0	80	0
Lamb Tups	46	0	30	0	32	6

The result of the Sale was most satisfactory, and Mr. White announced his intention of making it annual. Previous to the commencement of the business the company, consisting of about 200, partook of an elegant and substantial luncheon at the Farm House, and after the sale a party of between twenty and thirty dined with Sir Henry Smyth, at the Hall, when the breeding of the sheep, and agriculture generally, were the subjects of much interesting and practical conversation.

MODEL FARMS IN THE NORTH OF SCOTLAND.—We understand that, in imitation of the proposed model farms intended to be established in England, there is a proposal about to be made to institute one of the same kind in this northern district of the country, which, we have no doubt, will be a great advantage to the progress of agricultural improvements, as affording a specimen of the most approved modes of husbandry, which our farmers can visit and inspect from time to time.—*Inverness Herald.*

We noticed in our last a gigantic specimen of Tartarian clover, to be seen in the garden of Mr. Saul, near Lancaster, which had attained the extraordinary height of 8 feet. We have now to state that there are growing in the Manse garden of Applegarth, at this time, several hundred plants of the Mellot white clover, the tallest of which measures 10 feet 2 inches. The whole of the plants are still growing vigorously. The seed was got from Lawson, seedsman, Edinburgh.—*Dumfries Herald.*

PRICE OF MEAT.—By an act passed in 1532, the price of beef and pork was limited to one halfpenny, and that of veal and mutton to three farthings the pound avoirdupois (See Sir T. M. Aden's "State of the Poor," 4to., vol. i., p. 98). Subsequent statutes renewed former penalties enacted against forestalling and regrating, that is, purchasing any commodities on their road to market, and re-selling them under four miles of it. Persons who bought up corn or other articles of necessity, with an intention of holding them for future sale, were deemed unlawful aggressors, and cattle were not allowed to be sold within five weeks after purchase. The exportation of grain was also prohibited when the price of wheat exceeded six shillings and eight-pence the quarter. Stat. 1st c. 2nd Philip and Mary, 1553-4.

THE SCORCHER.

Sir,—I beg to inform you that the experimental trials of Mr. Winrow's patent scorchers have been completely successful, and I am satisfied it is the best and most effectual method for the destruction of the turnip fly; the hot blast from the furnace of the machine passing between the rows without injuring the plants, destroys the insects and weeds, and will perform from seven to eight acres per day with one horse.

I am, Sir, your obedient servant,
A CONSTANT READER.

Nottingham, June 13, 1840.

P.S. Mr. Winrow resides at Nottingham.

REVIEW OF THE CORN TRADE DURING THE MONTH OF AUGUST.

We have frequently had occasion to direct the attention of our agricultural readers to various defects which exist in the present corn laws, and more particularly to the manner in which the weekly averages of grain of all descriptions are collected. In our last review of the state and prospects of the corn trade, we ventured to state that, by a little well directed management in the average prices of wheat, a vast quantity of foreign grown wheat would in every probability be admitted into our markets of consumption on the payment of very moderate, if not actually nominal duties, and the result has done more than established the correctness of our anticipations; for upwards of one million of quarters of wheat, foreign flour included, will be speedily introduced into consumption, to the great injury of the agricultural interest, and of our public revenue. That this effect has been produced by admirably managed speculative purchases, in various markets of British wheat, at prices above the market value, does not admit of one moment's doubt; for, if any proof of this being the fact be wanting, it can most incontrovertibly be established by the prices of flour during the same periods, and by the decline in the value of bread itself which occurred during the course of last month. *Somebody*, under the signature of a merchant, in the Morning Chronicle, asserts the impossibility of monopolizing the British wheat market, which *everybody* must know to be a truism, but the average prices can be managed without resorting to measures which are impracticable, and more particularly when the rates of duties themselves are worth the attention of those who speculate on the importations of foreign grain. We recollect, about two years ago, *somebody*, in the same journal, after giving a dismal description of the appearances in the fields, predicted a general scarcity, because, after searching the world over in his imagination, half a million of quarters of foreign wheat could not be obtained to supply the expected deficiency in the crop of 1838, and as the merchant who is now figuring on the same subject in the Chronicle, is using assertions of a similar tendency, we strongly suspect that he should have used the signature, not of a merchant, but of an importer of, and speculator in, foreign wheat, or rather in the duties payable thereon when entered for home consumption. We shall not go the length which the writer of a powerful article on this subject, and published in the Herald, has gone, when he says that the average prices, latterly, have been raised by fictitious purchases of wheat, although we have more than once known the same parcel of wheat bought and resold three times on the same market-day at rising prices; of this, however, we have no cause nor reason to accuse the holders of foreign wheat this season, for it was well worth their while to operate fairly in the market, without resorting to fraud for the production of the desired effect. During the last two months, as is always the case at the same period of the year, the supplies of British wheat, generally, in the large markets of consumption, were small, and well-managed purchases of from two to three thousand quarters weekly during the then current six weeks are perfectly sufficient for the regulation of the

duties to be paid on the entry of foreign wheat for home use. That these speculative purchases must afterwards be resold at probably a heavy loss, is most certain, but a loss of a pound or even forty shillings per quarter, on twenty thousand quarters, which is the utmost length necessary to be risked in speculations for such purposes, is really a trifle if put in the scale with the money which may be gained from the reduction of duty alone. When these operations commenced, this season, the duty on the entry of foreign wheat was 18s. 8d. per quarter, and since then certainly nothing has occurred in the appearance of the coming crop to have caused any material reduction occurring in these rates of duties. The partial thinness existing in the winter wheats was then as visible as it is now, if it exist at all. By well managed speculative purchases, therefore, an object has been gained, which the elements, during the whole season, have hitherto denied; and the expense altogether cannot be more, on this occasion, than from twenty to thirty thousand pounds, probably not a tithe of this sum, for which sacrifice much above half a million sterling taken from the revenue itself, will eventually find its way into the pockets of the importers of foreign grain, and thus triumphantly enable these gentlemen to crown and conclude their present and late speculations in foreign wheats. The corn laws were enacted, not for the purpose of increasing the wealth of the importers of foreign grain beyond the usual profits resulting from commercial enterprises, but for the protection of every interest in the empire, whether trading, manufacturing, or agricultural, and it is a great defect in the construction of these laws, that a door is opened by them for making money, not out of the difference in the value of grain here and abroad, but out of the British revenue itself. Our farmers have taxes to pay whether the produce of their fields be large or small, whether the quality of their crops be good, bad or indifferent, and it is certainly not for the interest of the British community, that, under any circumstances, the foreign proprietors of wheat should not pay taxes to this country in proportion to the quantity of their grain consumed in our markets. When it is necessary to admit foreign wheat at all into this country for sale, 15s. per qr. is the lowest rate of duty which should be charged on it, for this is nearly the charge which is paid by our home growers, in the shape of public and parish taxes, and this charge should never be paid by the British consumer of foreign wheats, but by its foreign proprietor. To employ the inhabitants of foreign nations in the production of food for the consumption of the people in the United Kingdom is a policy perfectly at variance with all the rules of civil life. The value paid for the necessities of life to their home producers remains within the empire, whilst the money remitted abroad in payment for foreign produce is a total loss to the British community. In the one case it continues in circulation amongst manufacturers and other industrious classes, whilst in the latter instance it is the certain precursor of much individual distress. Whenever the season for securing the crop is unfavourable, a large amount of specie again is abstracted from the

circulating medium here, and remitted to the continent for grain, from whence it never does return, and a part, at all events, of the existing means for productively employing our population is thus withdrawn. The weather, certainly, during a part of August, was not so favourable as it might have been for gathering that portion of the crop, which was ripe enough for reaping, still as yet no injury of any consequence has been done by the partial rains which have fallen; on the contrary, to the later portion of the crop generally, and particularly to the potatoes, turnips, and pasturage, they have been of great advantage. Should the remainder of the season therefore only prove propitious, we still anticipate an average crop of wheat in quantity, and in quality greatly superior to that of last year. Indeed for many years past the quality of the new runs brought forward for sale has not been so fine, and little of it so heavy as it has proved to be this season, the whole being perfectly competent and fitted for the production of the finest flour, without any mixture of old or of foreign wheats amongst them.

Millions of acres of excellent cropping land are still in a state of nature in various districts throughout the United Kingdom. In the proposed county of Victoria alone, two hundred thousand acres may be reclaimed and rendered highly valuable to the commonwealth. In the harbour and bay of Wexford also, fifty thousand acres may be drawn from the water into cultivation, and rendered useful to the community; these benefits, however, cannot be obtained if our surplus capital be drawn out of the British empire in exchange for food which is not actually necessary to the wants of the people. On the contrary, a corn trade with foreign nations under such circumstances, must be a bar to such important improvements, and must deprive the people of wages, who otherwise might be so profitably employed in their cultivation. A part, at all events, of the ten millions sterling which during the two last years have been paid away for foreign food, would, had they been in circulation at home, been now most profitably employed in draining the waters in Norfolk and Lincolnshire from the new county of Victoria, and in clearing away the mud and other impediments in the way of cultivating the extensive wastes in the neighbourhood of Wexford, and indeed in almost every district in Ireland. Immediate employment, and fair wages to many of the productive classes of society, would be the first benefit derived from improvements of this description, and a vast addition to the agricultural produce of the empire must be their final result when they are completed. These great national advantages however, can never be obtained without the active agency of the corn laws, and their completion may be made more immediate by rendering these laws more protective to agricultural industry, and more favourable to the public revenue than they are at the present time. The manner in which the weekly average prices of grain are struck, we repeat may be made far more perfect than it is at present, and when necessity demands supplies of foreign grain for home consumption, a duty must be charged on its importation in some measure proportionate to the direct and indirect taxes charged on its production in the United Kingdom. Since our last publication, for instance, the reports from all the great corn markets have weekly and uniformly represented the supplies of English wheat as being every where more than usually small, and yet we find the quantities of that article returned latterly

to the corn-inspector for the purpose of striking the average prices which regulate duty, unusually large, and prices weekly becoming dearer. During two of the last six weeks in the London return, for instance, the quantity is more than double of the previous week's arrivals, and double sales of the quantity received consequently must have taken place, *for all the London granaries are at present pretty well cleared of wheats of British growth*; to have produced this effect, it is impossible for the corn-factors when they sell wheat, to know whether it be intended by the purchasers for grinding, or for speculative purposes, and consequently therefore, they can never make correct returns.

It is a curious circumstance, that since our last publication, notwithstanding the reported improvement in the value of wheat, flour has been exceedingly dull in the market, and to effect sales of this article much difficulty has been experienced, unless by those millers and flour-factors who submitted to lower prices; and it is still more extraordinary, that during the same period, one penny and a halfpenny of decline at least has occurred in the value of the four pound loaf. This paradox is far beyond our comprehension; we only mention the fact to show, in a better light, the many imperfections now existing in the mode of striking the weekly average prices of grain, and the actual necessity for a radical reform in the system, for until it be amended, similar scenes will now annually be enacted until they be concluded by a national convulsion, as well in commerce and agriculture, as in the wages of labour, in the revenue, and in the value of every description of property. In fact it must produce a virtual repeal of the corn laws, and must eventually be attended by all the misfortunes of a positively free trade in foreign grain. In consequence of this state of the corn trade, it is not possible for us to report the actual value of wheat since our last publication. Taking our opinion of it, however, from the prices of flour (its produce when manufactured), we hesitate not in saying that it is now decidedly cheaper than it was in the last week of July 1840, for meal-making purposes, whilst for regulating the duties payable on foreign wheats, it is certainly considerably higher than our quotations of it were at that date. We leave our readers to draw their own conclusions from these facts.

The transactions in the barley trade since our last review of this subject, have been exceedingly limited in their amount, and equally unimportant. The supplies during that period have been so unusually small, that it is not possible to quote the actual value of the article. The duty on its importation from foreign states is at present, however, a fair protective one to British agriculture, but, at the moment, the foreign trade in it, is not of much consequence, else, in every probability, it would not now have been so protective. The usual breadth of land was sown last spring with this article, and the appearance of the crop is at all events luxuriant. The heavy revenue, however, collected from the manufactured barley, is a most unjust impost on the cultivators of barley fields, in as far as it places a limit to the consumption of their produce. Twelve millions sterling annually is net the subject so much of complaint, as the manner in which they are collected. The rates of duty charged per quarter on malt, and per gallon on spirits, manufactured in England, are much too high. The same amount of revenue may be raised by the reduction of these rates one-half, and the consumption of barley may, and must be doubled by a relaxation in the amount of these charges. In the year 1810,

when the malt duty was 34s. 10d. per quarter, only three and a half millions of quarters of barley were converted into malt, whilst in 1836 at a duty of 20s. per quarter, the quantity of barley converted into malt increased to nearly six millions of quarters, a far greater increase than what then occurred in population. Another remission in the duty of even 5s. per quarter would raise the consumption of malt probably to ten millions of quarters, and when it is considered that our population now amounts to nearly thirty millions, one third of a quarter of malt annually to each person is but a very scanty allowance. But the benefit of a relaxation in the duties now charged on manufactured barley would not be confined to an increase in the supply of the people with malt. It will render necessary the cultivation of another million of acres of barley lands; the profits of this addition to our home tillage will add annually to the public wealth, and will do much more than pay for the expense of the additional consumption of malt, which the reduction on the duty chargeable thereon would most inevitably occasion. Above all, the alteration eventually will open new channels for the productive employment of the people, and increase the home consumption of every description of manufactured goods by the improvement which must be its consequence, in the wages of labour. To reduce the duty also now levied on spirits distilled in England, and to place them on a level with the charges in Scotland and Ireland, will improve the revenue, and will totally destroy the baneful system of smuggling, which the high duty in England encourages, and by which nearly one-third of the spirits now consumed in England are supplied. The reduction which occurred some years ago in the duty on home made spirits, inadequate as it was to the best interests of the empire, was however attended at all events by one advantage, in as far as the improvement which it occasioned in the science of the rectifier, caused English gin to be nearly universally substituted for Dutch Geneva, in consequence of the improvement effected in its quality. The time is not far distant when the consumption of French brandies must be reduced by the daily improvements which are now in rapid progress in the manufacture of home-made brandy. There is a national Cognac brandy distillery in King Street, Snow Hill, and several others throughout London, where the science displayed in this new branch of rectification already has considerably interfered with the trade of the foreign brandy importer, and were only the home distillation duty reduced to a fair rate, little doubt needs be entertained that British spirits will take the place of French duty-paid brandies, in the same way, as they have already superseded the use of Dutch duty-paid gin. In fact a considerable advance towards the completion of this important object has already been made, and under only proper encouragement, before long, the extract of British barley will generally be substituted for the spurious spirits which are now imported, partly legally, but by far the greatest part illegally, under the name of French brandy. In this way the consumption of barley grown at home may also be considerably increased, and the immorality of smuggling entirely suppressed. Above all, in the eyes of the Chancellor of the Exchequer, the revenue will be increased by the reduction of duty, and, to make the experiment, he will find himself producing an universal good, which cannot be attended by one solitary disadvantage to any class in our society.

In the oat trade, during the month of August, little animation has existed, and the variation in prices has been immaterial. In the oat districts in Great Britain, and throughout nearly the whole of Ireland,

the produce of last year's crop has been nearly exhausted, and we have had consequently to depend on foreign supplies latterly for our necessary consumption. This state of the oat trade clearly demonstrates the necessity of still more effectually, than we have hitherto done, protecting the cultivation of our own fields, and of affording every encouragement to further agricultural improvements throughout the United Kingdom; for had war, or other unforeseen circumstances deprived us at this time of foreign aid, in our oat consumption, the consequences would have been seriously felt by a great portion of the people. There are millions of acres of land now waste and entirely useless to the people, which may be reclaimed, we may say, from nature, and converted into excellent land for the production of oats, and surely our surplus population may be much more patriotically employed in improvements of this description, than in the cultivation of lands equally wild in our colonies. The United Kingdom has the means in the greatest abundance of supporting a far greater population than she now possesses, out of the produce of her own fields, and the rapid improvements now making in tillage of every description, must eventually render her a great exporting country of agricultural produce of various kinds. The present appearance of the crop is luxuriant, and a favourable harvest is only necessary to secure a most plentiful growth of oats, plentiful both in quantity and in quality. Should the produce of this article in Ireland only equal present appearances, the importation of it from abroad will not be necessary during the coming crop season.

With beans and peas we have been very sparingly supplied during some time back, but the demand for neither of these articles has latterly been active, and it has chiefly been served by foreign importers, who have made their purchases abroad and their sales here, the former on moderate terms, and the latter on the payment of the lowest duty chargeable towards the public expenditure of the United Kingdom. The quality of the new peas is most excellent, the growth of both is abundant, and we expect the condition of beans will eventually be good, and in every respect equal to that of peas.

The potato crop will prove a plentiful one, and the quality of this most necessary root, second in importance to the people only to wheat, will be of the first description. The late rains have been very favourable to the improvement of this article, and have been most advantageous to turnips, to pasturage, and in that generally to every description of green cropping.

The information latterly received from abroad, respecting the state of the corn trade and its prospects, is of the usual description. The letters from Mark Lane regulated exportation shipments in all the great markets, and prices depended, at the latest advices, entirely on the value to be obtained here, and on the probable duty to be charged on entry for home consumption, their internal consumption not being of so much importance as to fix the value of wheat in the uncertain state of the London market. From the United States of America, letters dated in the first week of last month, represent the harvest throughout the Union as having been concluded, and they report the produce as being large, and the quality of a superior description. Prices continued then moderate, although some animation had been created by the accounts previously received from England; considerable purchases had been made, and the shipments to our markets would be much increased as soon as the new wheat and flour could be transported from the

interior to the great ports of shipment. From these states we shall certainly receive large quantities of wheat and flour before the conclusion of the present year, and time will show whether the speculations will turn out profitable. From the president downwards the benefit to be derived from the cultivation of the fields at home, formed the universal subject of conversation. Their agricultural resources are boundless, but the markets for consumption are limited, and this forms a topic for general complaint. In this the English Corn Laws take the lead, and because the legislature here prefer the British landed interest to that of the United States, every mercantile letter almost is filled with the most violent vituperation against these laws. The American wheat growers, it seems, could send to England alone, out of the surplus of their produce, wheat to the value of forty millions of dollars annually, and to provide for them a market of consumption to this extent, they consider the ruin of the British agricultural interest of minor consideration; if we received grain from America alone to the value of four or five millions sterling annually, there are in Europe four or five nations, which would naturally expect from us acts of equal generosity. It would be rather expensive, however, for Great Britain to pay at least twenty millions sterling annually for this character of generosity, amongst foreign nations; indeed we rather suspect that insanity would soon be substituted for generosity by the American gentlemen themselves. But the American agriculturist it seems intend speedily to compel a relaxation in our corn-laws, else our trade with them will be destroyed. Iron, woollen goods, glass, in short every article of British manufacture are to be interdicted, and the ruin of England is to be the necessary consequence. From these complaints however the British people may receive much instruction, for they will learn that, was the foreign corn trade entirely free, the ruin of our agricultural interest would be the inevitable consequence. The ruin of commerce would speedily follow that of agriculture, and the specie and wealth of this great empire would soon afterwards be exhausted, and universal distress and turbulence would reign amongst the people now generally so prosperous and contented with their condition in life. From Southern Europe the information received in course of post represents the crops as being most abundant as well in quantity as in quality. From the Black and Mediterranean seas considerable quantities of wheat will be received here before the close of this year, and this quantity will be increased by the fact of a large crop having been secured in France, in excellent condition. From Poland, and indeed from every other corn district on the continent of Europe, the news is equally satisfactory, and should we want supplies, we will receive them in abundance, so long as specie and credit are to be found here. From the Baltic ports large shipments have already been made, and many more will yet be made in consequence of the present reductions which has been brought about in the rates of duty payable on importations. If September only prove favourable, however, for securing the remainder of our crop at home, we doubt much whether these latter speculations will be very profitable.

DISTRICT REPORTS.

From all the Hop districts we have a deplorable account of the damage done by the late gale of wind;

many planters affirm that it was quite as bad as the visitation we had of a similar kind in 1833. Mid-Kent, where the Hops appeared most promising, has suffered much in consequence. Hops will be hops again at 20l. per cwt.; and it is now very doubtful whether the duty will reach 20,000 this season. It is feared, unless we get some sunny weather, that the quality will be bad, and the hops light, wanting condition.

HAWKHURST HOP FAIR, Aug. 11.—This annual fair took place here to-day, and we fear but little business of any kind was done. It may be considered as one of the first fairs in the year, at which, generally speaking, anything like a probable estimate of the hop plantations can be ventured on, but the present appearance of the hop gardens in this and the adjoining parishes is such as to leave little room for speculation as to the quantity likely to be grown, for one and all (except the very large growers) gave it as their opinion that the generality of the small planters would scarcely get enough for their own consumption. The duty was called 40,000l., but we really begin to suspect that it cannot now realize any thing like this amount. The prices of Weald of Kent hops varied from 6l. 10s. to 7l. 10s. per cwt.

SEED MARKET.

Aug. 24.

The demand experienced for Cloverseed in bond some time since has entirely subsided, and quotations are now perfectly nominal. Linseed maintains its previous high value. The price of Rapeseed remained unaltered. New white Mustardseed may be quoted from 12s. to 15s., and brown from 18s. to 23s. per bushel.

WOOL MARKETS.

BRITISH.

Aug. 24.

English Wool remains stationary as to prices—the apprehensions for the state of the harvest excited by the very unfavourable state of the weather which prevailed the beginning of the week, and the unsettled state of Foreign affairs, and the high price of corn, probably producing averages high enough to induce the holders of foreign grain to let out the bonded corn, so as to require the precious metals, has caused a dull demand for Wool, and prices of various sorts barely maintain former rates, and although a fair attendance of buyers yet Colonial and other Foreign Wool are the only things moving off, unless it is at a loss to those who bought fleeces from the farmers in July, which with the attendant expenses of collecting, &c., are indeed ruinous. The present appearance of a return of fine weather, however, it is to be hoped and expected, will brighten prospects a little and cause an improvement in demand, but as Foreign Wool is a turn the easier, it is to be

feared the grower and dealer in English wool will not continue to realize the present prices, which are as per last week's currency.

LIVERPOOL, August 22.

SCOTCH.—There continues to be a fair demand from the trade for new laid Highland Wool as it arrives, really good combing parcels fully realise our quotations, but purchases are made with very great caution, on account of the very unsettled state of the weather. There continues to be a very limited inquiry for both crossed and Cheviot Wool, most of the dealers and manufacturers having for the present supplied themselves direct from the farmers.

FOREIGN.

THE WOOL TRADE, LONDON, THURSDAY EVENING.—Since the conclusion of the public sales we have to notice no alteration in price. The imports are now becoming very limited. In the week ending to-day they have been 367 bales, comprising 109 bales from Spain, 181 from Germany, 53 from Russia, and the rest from the Cape of Good Hope. Accounts from Sydney of April last, notice an auction of wool at which 20 bales realized 1s. 6½d. per lb., 11 bales 1s. 6¼d., and one bale in the grease 7d. per lb. The total imports of Colonial wool into London, Liverpool, Hull, and Goole, this year, have been 25,701 bales, and of Foreign 73,739 bales.

IMPORTS OF WOOL.—Quantity of wool entered at Hull for Home Consumption, during the week ending August 13.

From Hamburg	851,241 lbs.
Odessa	40,000
Copenhagen	36,000
Stockholm	1,500

THE FARMER'S MAGAZINE.

OCTOBER, 1840.

No. 4.—VOL. II.]

[SECOND SERIES.

PLATE I.

The subject of our first plate is the short-horned yearling heifer "MERMAID," the property of R. M. Jaques, Esq., of St. Trinians, Yorkshire, for which a prize of Ten Sovereigns was awarded at the second Annual Meeting of the Royal Agricultural Society of England, convened at Cambridge on the 15th of July, 1840.

PLATE II.

PALMER'S PATENT PLOUGH.

[The following is the description of this Plough given by the Patentee.—ED. F.M.]

The Construction of this Plough is peculiarly novel, unlike any other ever offered to the Public; possessing greater advantages in every point of view,—its adaptation to various soils and seasons. The body of the Plough moves upon a wheel, following the track of the share, instead of sliding and compressing the earth, so much complained of in other iron Ploughs, consequently friction is reduced and facility given to its action, and a considerable saving of labour to the horses is thereby effected. The wear and tear in materials is also reduced. The ploughman has a thorough command over his plough, as it works easy in hand, and is enabled to set it deeper or fleetier instantaneously, as hard and tender land, wet and dry seasons, may require; and one particular feature in this Plough is, it will plough the hardest land, an advantage much appreciated, as one dry ploughing is said to be worth two wet ones. The greatest nicety in the draught is assisted through a peculiarly constructed hake, no way likely to get out of order; indeed every day's information affords to the Patentee encouragement to hope these Ploughs, from their proved utility, will supersede all others; as every attention will be paid to the various mould boards or breasts required or suggested from time to time, and in point of economy one sight will satisfy on that head, being freed from all those variety of parts such as chaps, slides, side caps, keeps, loops, wedges, punches, &c., &c., expensive to employers, and troublesome to men.

ON THE PLOUGH.

IN ANSWER TO MR. DANDY HARWOOD,
BLAXHALL.

SIR,—In the conclusion of your remarks on the Kentish turnwrist plough, you say that if a turnwrist plough can be produced, which requires no greater power to propel it than others, and which performs its work equally well, it is equally

OLD SERIES.]

worthy of notice, as the two horse fixed wrist plough.

Now sir, in answer, I beg to inform you that I have, through the kind assistance of Messrs. Ransome, made an iron turnwrist plough, which is drawn only with two horses, and have tried its draught in competition with four other ploughs, the two-horse fixed wrist plough included, and herewith send the particulars, Mr. Ransome being present with his dynamometer.

T

[No. 4.—VOL. XIII.]

Ploughing a turnip fallow that had not been ploughed since Christmas, on April 24, 1810, eight inches deep.

	cwt.	qrs.	lbs.	
Little two horse turn-wrist.	draught	4	2	0 10 turn to the rod
Two horse patent fixed wrist plough.	do.	4	3	0 11 do.
3 horse turnwrist. (Messrs. Ransome's)	do.	5	2	0 0 do.
Kentish four horse turnwrist plough.	do.	5	2	0 0½ do.
Norfolk wheel fixed wrist plough with standers.	do.	4	1	0 11 do.

In order to ascertain whether my little two-horse turnwrist plough would prove equally as light to break up, we took all the ploughs in a rye field fed off, to be ploughed up for turnips. The result as follows :—

	cwt.	
Kent four horse plough.	draught.	6½
Little two horse turnwrist plough.	do.	5½
Ransome's 3 horse do.	do.	5½
Patent two horse fixed wrist do.	do.	5½

8 inches deep.

The soil is dry, a mixture of chalk and loam with flints, which renders the patent fixed wrist ploughs useless, they not being able to contend against the flints, consequently they are thrown out of their furrow repeatedly, and cannot maintain an even depth, nothing but a wheel plough will contend against our flints.

Now sir, by this statement, which Mr. Ransome is a witness to as well as myself, I contend that we have accomplished a Kentish turnwrist plough to go with two horses lighter than your *two-horse fixed wrist plough*, and the lightest going plough was the Norfolk wheel fixed wrist plough, but it did not do its work near so well as our little two horse turnwrist plough, and the patent two horse fixed wrist plough could not keep its depth on account of the flints, and consequently did not do its work well at all. Now sir, as these statements are true, and facts are stubborn things, I beg to deny that your plough is capable of ploughing up everything but a prejudice, and that I am fully convinced from practical experience, for I have now tried almost every plough on our land, in fact, every plough that is at all likely to plough it, that our Kent turnwrist plough is the most complete instrument for ploughing our land, and that we can do it with two horses better than any other plough can do it, (your plough not excepted). The prejudice in Kent is sticking to four horses and a great unwieldy plough, with a man and a mate all half asleep, which requires great exertion to turn, where my little turnwrist shall go by them, with two horses contending against each other for speed, and a man behind with reins, altogether doing their day's work with greater ease and quickness. Four horses are perfectly useless, almost at all times with these big ploughs, and I have no doubt the time will come when I shall be able to plough up their prejudice (being a Kentish farmer) sooner than it would be ploughed up by a man and plough of any other county. This is the only prejudice our Kentish farmers have, in having four horses and a large plough to plough all the year round, whereas I plough with two horses and a small plough all the year round, excepting in very stiff land, or broadsharing, (a little plough with a broadshare would not keep in the ground, and greater strength is wanted to broadshare, or breaking up in the summer after wheat,) then four horses and a large plough is wanted. I have thought it right to write this, to let you know that we are not all of us prejudiced in four horses, nor in our

ploughs, but find there is no other instrument yet produced, that can plough our land properly.

Messrs. Ransome have one of our turnwrist two-horse ploughs now at their foundry, to make a few improvements upon, which you can see on application, to be a perfect little instrument far surpassing anything ever yet invented, and I have not the least doubt, after a few years, our Kentish farmers will see the great advantages derived by ploughing with two horses instead of four, with the same implement, which now is the only prejudice the Kentish farmers can be accused of.

I am, Sir, your obedient servant,
 Kent.
 ADDIS JACKSON.

ACTION OF MANURES.

(FROM THE CULTIVATOR.)

Of the importance of manures to the cultivator of the soil, there seems to be but one opinion. The practical man and the theorist both are compelled to admit, that a plentiful supply of manure is essential to success in farming; and experience proves that few things are more true than the Flemish maxim, "without clover no cattle, without cattle no manure, without manure no grain crop." The nature of the action of manures, or the manner in which they produce their good effects, does not, however, seem to be equally clear with the points before mentioned; at least, there seems to be a greater diversity of opinion on this topic, a thing perhaps allowable when it is considered that it is less a matter of direct observation than the others, and that even men of science do not appear to be perfectly agreed in all their conclusions respecting the laws of vegetable nutrition.

To produce vegetation, three things seem to be indispensable; moisture, warmth, and a communication with the earths. Deprivation of the two first is certainly fatal to plants, and though where the two first are present and the last absent, yet the perfection of such plants is never complete, and fruits are never formed. Thus an acorn, suspended by a string over a glass of water at a proper temperature, will vegetate, and while the roots seek the water the young plant will extend upwards, yet the growth will continue no longer than the substance of the acorn affords nourishment to the young shoot. Fill the glass with earth, and if watered, the growth will continue so long as nourishment and space are afforded. It would appear then to be clear that the union of these three things is necessary to the growth and perfection of plants.

There was a time when it was believed that plants derived their support entirely from water, and that if a suitable supply of this was provided, it was all that was required, and that the use of the earths was only to serve as a reservoir or repository of this fluid for the use of the plant. This idea of water being the sole nourisher of plants, may be traced through Greece to Egypt, an origin, or opinion, not surprising among a people who yearly witnessed the fertilizing effects of the waters of the Nile, on the apparently barren sands of that country. The large quantity of sediment brought down by the river, appears to have been overlooked in their estimate of fertilizing causes, though it is now well understood that of all substances such deposits are the most valuable. This opinion was revived and apparently confirmed in the 17th century, by the experiments of Boyle and Van Helmont. The wil-

low tree of the latter, planted in a tight box, lined lead, the earth and tree carefully weighed at planting, watered with rain water only, and after a few years growth, both the earth and tree again weighed gave a gain, which, when it was ascertained that the earth had diminished only a few ounces, was deemed conclusive as to the nutritive power of water. It remained for later philosophers, by the analysis of rain, and other water, to show that the substances required in the growth of such plants were contained in abundance in the fluids employed.

When water, made chemically pure, is employed in that state to promote the growth of plants, a failure is the certain and inevitable result. That able experimentalist Cuthbert Johnson, has varied his experiments in every form, and always with the same termination, the death of the plant, in a longer or shorter period. Dr. Thompson was equally foiled; he finding that plants so treated vegetated only for a short time and then failed, never perfecting their seeds. Other experimentalists have been equally unsuccessful, and the theory now more rationally adopted, is, that water is only valuable as a solvent for the nutritive matter required by plants; in other words it is only useful as a liquid manure. Some plants of the bulbous rooted kinds, that are made to flower in water, such as the tulip and hyacinth, are obliged to be planted in the ground every other year, or they refuse to flower, or even, finally, to vegetate. This is accounted for by the fact that the store of nutritive matter provided by nature in the bulb, and drawn from the earth, was exhausted by vegetating for one season in water.

It has been supposed by some, the earths most common in good soils would, if watered with pure water, support vegetation. But the experiments of M. Giobert proved the fallacy of this supposition. He mixed silica, alumina, lime, and magnesia, in the proportion in which they are found in the best soils, and then in vain attempted to grow plants where pure water was used. This was not the case when water impregnated with animal and vegetable matter, or that from a dunghill was used, as the most luxuriant vegetation ensued. All the efforts to induce plants to appropriate to their growth matter in any other state than that of solution have failed. The finest and most impalpable particles of matter are rejected equally with the coarsest. Davy ineffectually tried charcoal, reduced to the finest possible state; and Chaptal and Johnson equally failed with the earths, saline substances, and with other organic matter. All nutrition, then, in plants, as well as in animals, is performed by substances in solution, or aëri-form; and it is hence also evident, that manures are only useful to plants when presented to them in a liquid form, or when they assume that form in the earth by combination with water.

We have before expressed our full conviction that all vegetable growth, or nutrition, is the result of a chemical action not dissimilar to that of the voltaic battery, or the agency of electro-magnetism. Of the existence of such electro or voltaic currents, vegetation itself furnishes the most conclusive proof. To this the vegetable sensibility of the mimosa must be attributed; and the currents as they exist in the fluids of plants, may, under the microscope, be distinctly observed in those plants with transparent cuticles, such as the *Caulina fragilis*, or *Tradescantia virginiana*. We further infer this action from the general similarity existing in the functions of vegetables and animals, and their nutritive powers. In animals the nervous system furnishes conclusive evidence of such agency, and the organization of the plant may not unreasonably be referred to the

same cause. "Perhaps," says Professor Henslow, "until the contrary is proved, we may consider the addition of sensibility, to the living principle, as the characteristic property of animals; a property or quality by which the individual is rendered conscious of its existence, or of its wants, and by which it is induced to satisfy these wants by some act of volition." Dr. Green, in quoting this passage from Prof. H., goes farther, and says, "We are inclined to the belief, however difficult it may be to demonstrate it, that a quality strictly analogous in its results, to this property in animals, belongs to vegetables."* Every new truth in vegetable physiology goes to confirm our previous opinions of the nature of vegetable nutrition, and develop the rationale of manures. The earths will not cease vegetation, be they ever so nicely proportioned; water cannot support the plant, when used in a pure state; the salts of manures, constituting their most efficient part, are fatal to plants in a concentrated form, or when present in too large quantities; but when these are combined, the growth of the plant they are brought to act upon, is certain and rapid. It is scarcely possible there should be a clearer or more beautiful illustration of the nature of the chemical action necessary to the growth of plants than this combination affords. In this case the different earths constitute the battery for the generation of the voltaic current, the particles constituting the plates of the great machine of nature, and the finer the earths are made the greater the number of pairs, and consequently the more active in their results. In itself, however, this battery is powerless; it is only when the plates are plunged in an exciting fluid, when water containing the salts necessary to produce this action is applied, that this current, so indispensable to the growth of plants, indeed without which no vegetable (and perhaps no other) organization is possible, is fully developed. To us this philosophy of vegetation appears extremely simple and natural, explaining more satisfactorily than any other theory, the action both of vegetable and mineral manures.

If the plates of zinc in the common battery are corroded or destroyed, or those of copper rendered worthless by continued action, it is clear these defects must be supplied before the desired effect can be produced. So if any of the necessary earths be absent, or if they have been exhausted by cultivation, a healthy vegetation cannot be expected, until this deficiency is remedied. And if the proportions of earths are ever so perfect, if the exciting agents, the salts and the water, are absent, there can be no growth; the current, which alone carries into circulation the substances that go to the formation of the plant, cannot exist. In this way only, can the prodigious fertilizing powers of some liquid, or dry manures that when applied to the soil become liquid, be satisfactorily accounted for. Urines, poudrette, and the sewerage water of large cities are instances of this kind of agents.

But whatever opinion may be entertained of the theory here advanced, it cannot be disputed, that independent of the substances more particularly necessary to excite voltaic action, there are few articles so rich in the materials required by plants, as what are termed the liquid manures, or the drainings of the barn-yard or the stables. This fluid contains the most essential of the salts employed in accelerating vegetation, and their loss to the farmer

* See an ingenious paper on "Vegetable Organography and Physiology," in the 77th No. of Professor Silliman's Journal. The instances given in proof by Dr. G., are not satisfactory to us.—*Eds. of Cult.*

is irreparable. There is some little difference in the constituents of the urine of different animals and of man, but the analysis of one, and we select that of the cow, by Prof. Brande, will give a sufficiently accurate notion of the constituents of this substance, and the loss occasioned by not converting it to its proper use in promoting vegetation.

Water	65.0
Urea	4.0
Phosphate of Lime	3.0
Muriates of Potash and Ammonia	15.0
Sulphate of Potash	6.0
Carbonates of Potash and Ammonia	4.0
Loss	3.0
	<hr/> 100.0

Barn-yard manure, after it has been deprived by solution, by washing, and by evaporation of these essential animal and vegetable salts, is very little better than common vegetable mould. Its efficiency in promoting vegetation is gone with the exciting agents it has parted with; the remainder is only the earths which have formed the frame-work of the plants, consumed or decomposed, useful indeed, but wholly wanting in the power they once possessed.

To show the difference caused by the presence of these agents in enabling plants to take up the matters necessary for their perfection, we give the following from a statement of Prof. Johnson:

"I caused beans to vegetate under three different circumstances; the first were grown in distilled water; the second were grown in sand and watered with rain water; the third were sown in rich garden mould. The plants thus produced when accurately analyzed, were found to yield the following proportion of ashes:

Those watered with distilled water	3.9
Those " with rain water	7.5
Those grown in garden mould	12.0"

Garden mould, or soil, more than almost any other abounds in these prominent elements of fertility, and the above experiment proves conclusively the importance of their presence, where luxuriant vegetation is wished or expected.

Liquid manure, then, may be considered one of the most valuable agents in the production of crops. But its use as practised on the continent of Europe, and in China, cannot be expected here; it has as yet scarcely been introduced into England, though where it has been tried its benefits have been most decisive. The additional labour required in the German or Flemish use of this manure is so great that their system unless in some limited cases, cannot be expected here; the cost would exceed the income. There is no necessity, however, for the frightful waste of this valuable material that we witness in every part of our country. Instead of this fertilizing fluid being converted to a profitable use, the great object, with multitudes of farmers, seems to be, how they shall get rid of it in the easiest manner. Ditches are constructed from their yards or stables to the highway, and the neighbouring brook or river, to carry off the precious article, as though it was feared the surest means of fertilizing the soil, or producing great crops, would accumulate too rapidly.

It is to the accumulation of such salts that the sewerage of cities owes its fertilizing properties, when employed for the purposes of irrigation. A striking instance of this power appears in the astonishing increase of the grass crops on the water meadows near Edinburgh since the water from the drains of that metropolis have been applied to their irrigation. This result will not be surprising to any one

who reflects on the composition of such sewerage; "its endless mixture of organic matters, its soot, its carbonate of lime, its decomposed animal matter, and above all its urine," combine to produce one of the most active stimulants of vegetation known.

But if farmers cannot at present in this country be at the expense of the vats for converting the whole or the most of their barn or stable manures into liquid manures, or the costly apparatus for its distribution, they can do much to prevent its waste by furnishing the means for its absorption, where there is an excess, as there usually is in the vicinity of the yard or stables, and thus save it for the use of the soil. To do this it is necessary, in the first place, that some cheap and easily constructed reservoir should receive these drainings when they are formed. In most yards a hollow may be made, without lining, if the soil is retentive, but if porous, with a lining of clay and imbedded pebbles, and this, if filled with swamp earth, the sandy wash from the roads, or even common earth, will absorb large quantities of this liquid manure, and thus obtain a fertilizing power, equal, if not superior, to that of common barn-yard manure, treated in the ordinary manner. These earths brought to the yard, become thoroughly impregnated with the salts and other fertilizing matters of the yard, and thus preserve for the farmer what would otherwise be lost to his use. In many cases where the cattle and sheep are folded in open yards, a covering of vegetable mould, swamp earth, &c., spread over the yard after it has been cleared out, to the depth of a foot, will prevent much waste by its absorbing power, and being thoroughly mixed by the feet of cattle with the ordinary manure, will be found in the spring when wanted for use on the field a most valuable manure. In this way, some farmers add to their stock of fertilizing materials some hundreds of loads annually. One of the most successful farmers of New-England, Mr. Clark of Northampton, has pursued this system to a considerable extent, and with marked benefit. Others also, have tested its use, and speak highly of the practice, as corresponding perfectly with the theory.

Various opinions have been entertained of the utility of piling barn-yard manures when not wanted for immediate use, or the propriety of placing them under cover. It not unfrequently occurs that the stable or yard manures made during the winter, are not required for the spring crops, and are reserved for those to be sown in autumn. The question now arises, how shall this manure be disposed of during the summer? If it remain spread over the surface of the yard exposed to alternate sun and rains, it appears clear that the most valuable parts of it, the salts and animal part, must be lost in such a course. If piled, and left without farther care, it is very apt to be damaged by excessive heat in the fermentation, and the consequent escape either in the form of gas, or that of a thick black liquor from the base of the heap, of these essential agents of fertility. Some farmers, aware of these disadvantages, have piled their manures, but in such a way as to prevent the loss or escape of any of these valuable constituents. With a little extra labor, added to that required for ordinary piling, they have converted the contents of their yards into a proper compost, greatly increasing the quantity, while all the valuable qualities are retained. This is effected by placing the fresh manures in alternate layers with such earths as we have noticed before, these earths becoming impregnated with the evolved gases, while they at the same time absorb and retain whatever liquid matter may escape from the dung during the process of fermentation. The height and breadth of these mounds must depend

on the quantity of manure to be treated in this way, and the facilities for piling it at the command of the farmer.

Perhaps the most satisfactory test of the relative value of manures, may be found in the series of experiments instituted at the request of the Prussian government, by Professor Hembstadt of Berlin, and repeated with every kind of variation, by Professor Schubler, with the same results. The following table, prepared with great care from the record of those experiments, will show the value of the several manures named, on soil of the same quality or productiveness.

"If the soil without any manure yield a produce of three times the quantity of seed originally sown, then the same quantity of land when manured or dressed with herbage, grass, leaves, &c., will yield

5 times the seed sown.

When manured with cow-dung.....	7
With pigeon's dung.....	9
With horse dung.....	10
With human urine.....	12
With sheep dung.....	12
With human manure or bullock's blood.....	14

Thus if before manuring, an acre of land with two bushels of seed, would give a produce of six bushels, the same acre manured with urine would give twenty-four bushels; and if with bullocks blood, twenty-eight bushels. Experience shows that with roots and grasses the difference will be about as great on soils of the same quality; and these facts evince more conclusively than any reasoning can, the value of such manures, and the necessity there is of the farmer's making the best possible use of them, if he would succeed in his occupation.

THE DERBYSHIRE FARMS.

TO THE EDITOR OF THE FARMER'S MAGAZINE.

SIR,—I am the occupier of a considerable farm in the hilly part of North Derbyshire. We have some good grazing and mowing lands amongst our hills, and our rents are not apparently high. We have also good markets for much of our produce; but notwithstanding these seeming advantages, the greater part of the farmers in these hilly districts who have no other incomes than the profits of their farms, are poor.

It has long been my opinion that we must have some heavy disadvantages to contend with, that our brother farmers in the southern counties were in a great measure exempt from, and the object of this letter is to point out some of them.

The first that I shall mention is the shortness of our summer season, and consequently the length of our winters. On this account we are obliged to appropriate a far greater part of our farms for the supply of winter food for cattle, than is needful in the southern counties. And with respect to our summer grazing, it is generally the middle of June before our pastures can be fully stocked, and by the middle or end of September, frosty nights become so prevalent, that both grass and cattle cease to grow, except in some sheltered situations; there is therefore not time to feed a large sized Yorkshire beast, except it be bought in half fed, and then the price is high, and being obliged to be sold out in September or October, when beef is at its lowest

price, the profit for grazing is but small. It is not so with graziers in the southern districts, they can buy in a great part of their feeding stock in February or March, and by the help of a little hay in those months, can keep their cattle growing, so that by the end of June they are ready for the butcher at a time when beef is high in price. They then buy for a second crop, and not being subject to our severe night frosts can keep them growing until Christmas, when the price of beef again gets higher, so that had we our grazing lands rent-free, they would still have an advantage over us. But there is another disadvantage which our hilly farms lie under, that is sufficient of itself to account for our poverty without any other. It is a truth which few will deny, that grass, corn, tares, and many other things which the earth produces, have a natural tendency to grow up perpendicular or upright. This being admitted, it will follow as a truth equally clear, that whatever may be the surface of a farm as to hills and dales, or whatever may be its admeasurement, its produce can be no more than what the flat area or base upon which the farm may be said to rest would produce.

To make this appear more clear to my brother farmers amongst these hills, and others whom it may concern, I would suppose two thin boards to be cut to an equal size, say three feet long by two feet wide; lay these boards one exactly upon the other upon a level table, then mark the upper board into squares, or fields, so as to represent a farm of any given quantity, say 100 acres, and the under board would represent the flat base upon which the farm rested, and would likewise be 100 acres, but raise one edge of the upper board so as to represent the farm as being sloping, or on a hill side, it would still measure 100 acres, but its power of production would be decreased, inasmuch as you would have reduced the base upon which the farm rested, and the higher you raised the edge of the board the more would this be the case.

Again, suppose the two boards laid flat on the table as before, they would then as before, both represent 100 acres; lay upon the upper board or farm, a number of wash basins at short distances one from another, and with their bottoms upwards, it might then be said to represent the farm as covered with hills and dales, such as we have many in this district. Send a land surveyor to measure this farm, he would take his lines over hills and dales in the different parts of the farm, and the result of his admeasurement would probably be 130 acres.

At this measure it is let, and the tenant has to pay rent, taxes, rates, and in many cases wages also, according to this admeasurement. But what is the produce? Why the produce is no more, nor can be than the produce of 100 acres, which the flat surface of the board or farm represented before these basins or hills were put upon it.

What I have here stated I believe to be the chief and true causes of our poverty.

A NORTH DERBYSHIRE FARMER.

FARMER'S INSURANCE INSTITUTION.—

By the plan of Deferred Annuities just announced by this society, a single deferred annuity is made, not only to answer the same object, but to equal in amount the entire sum of all the advantages heretofore only obtained by the middle and industrious

classes by separate investments in Savings' Banks, Benefit Societies, and Loan Banks.

1. A small yearly or weekly contribution will secure the most ample return for after life. Thus: the payment of 2*l.* 12*s.* per annum (1*s.* a week) beginning at 20 will at 65 entitle the party to an annuity for life of upwards of 47*l.*

2. Two-thirds at any time will be lent on the deposit of policy, being a fund always available during sickness or want of employment.

3. The whole or any part of the money will be returned to the policy holder whenever required, or to representatives in case of death before the stipulated age.

NOTES OF AN EXPERIMENT WITH GYPSUM.

My farm, on which the experiment was made, has long been under clover. It is and has been for the last twenty years, carried on upon the four course system. It is now impossible for a full crop of red clover to be grown upon it. In order to remedy this, gypsum had been recommended by Davy, &c., which I determined to try. Last year I had a piece under red clover. It is the best piece of land in my little farm, and had been limed for the crop of turnips the two years previously. The plant was generally well set after the harley was reaped. The soil is light loam subsoil, a porous gravel, and perfectly dry.

I staked a piece out in March, 1839, and applied grossly powdered gypsum at the rate as near as I could guess of about three bushels per acre.

I watched the plot narrowly through the summer but it partially failed like the rest, nor could I see any greater vigour in the plants which remained, nor could I perceive the slightest difference in the second crop upon the gypsum piece, nor any difference in the subsequent crop of wheats. I ought to have stated that the gypsum was not calcined.

On a previous occasion a friend presented me with a cask of chemically prepared gypsum (*sulphate of lime*). I laid it on in May, on a wet morning at the rate of about three bushels per acre, soil sandy—subsoil, white sand with an occasional stratum of gravel. I could not perceive the slightest improvement in the crop over that where no gypsum had been applied.

MATTHEW MARMADUKE MILBURN.

ON SALT AS MANURE.

Kent, Sept 20, 1840.

SIR,—Will you have the goodness to inform me in your next publication, whether Salt used upon ploughed ground in a fruit plantation will injure the fruit trees or not, also what quantity of that article is requisite per acre in stony ground.

Your obedient servant,

A YOUNG FARMER.

“The quantity per acre for strong fallow ground, is from sixteen to twenty bushels per acre. So far from injuring the fruit trees, it will promote their general health; the application of salt to apple orchards for this purpose is an old custom in Herefordshire—why does not our correspondent mix the salt with lime?—say 20 bushels of salt and 40 bushels of lime, mixed dry, and not spread on the land for three months?”—ED.

JETHRO TULL.

MY DEAR SIR,—It is now exactly a century since the death of Jethro Tull, the great father of the drill husbandry, a man whose services to agriculture have rarely been equalled, and never excelled. At this centenary anniversary of his death, might it not tend to the honour of the professors of that science, which Tull laboured so ardently, and so perseveringly to advance, if they were to commemorate his death by some agricultural meeting? For instance, by having a public dinner? The great English naturalist John Ray, had a similar tribute paid to his memory some few years since, by a public meeting of men of science, and ought not Jethro Tull's services to the cultivators of the soil of England to be remembered with equal gratitude? Such a meeting would not only do honour to the agriculturists of our country, but it would be another convincing proof that though Tull's contemporaries opposed and ridiculed all his efforts to improve the fertility of the land, yet that a succeeding generation, made wiser by experience, at last paid that tardy homage to his memory which true genius is ever sure eventually to receive. As there is no paper that circulates more widely amongst the leading farmers of England than your own, I beg leave through its pages to offer these remarks, and to express my willingness to co-operate in the best way in my power with those who may deem the suggestion worthy of being carried into execution.—I am, my dear Sir, yours faithfully,

CUTHBERT H. JOHNSON.

14 *Gray's Inn Square, August 20.*

DIBBLING MANGEL-WURTZEL.

SIR,—I and many of my neighbours dibbled in our mangel-wurtzel seeds in the first week in April last; they made their appearance very regularly, and advanced in growth rapidly, but I think I may say, one-fourth of them has run to seed. I should be really obliged if some of your many correspondents and readers would favour me with their opinion, through the medium of your excellent publication, of the cause which induces me to trouble them, to inform me whether they know from experience, that mangel-wurtzel seeds put into the ground at any particular period, is liable to run to seed, as ours have done? or whether it is imputable to some defect in the seed? or that the seed has been the produce of untransplanted bulbs? The sort we planted and prefer, is the yellow globe.

Now, as I have the pen in my hand, and as the wheat-sowing season is approaching, I will add a few words on that subject. I believe that the received opinion is, that the seed of corn of all kinds, should be obtained from a better soil and climate than that where it is to be sown. I know that my neighbours and I, in general, get a part of our seed-wheat from Bristol, and the sort preferred is the red Lammas, but it is found always to degenerate. Now, I entertain a notion, that we ought rather, as change of seed is found to be advantageous, to procure it from a colder and wetter climate, with the expectation that instead of degenerating, it would improve in quality and productiveness, and I have, (in consequence of having formed perhaps an erroneous opinion,) ordered seed-wheat from the west of Scotland. If you, Mr. Editor, or any one well qualified, would favour me with your or his thoughts upon the subject, you would very much oblige your regular reader,

E. H.

Haverfordwest, Sept. 3.

ON SMUT BLADDERS IN WHEAT.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—I read in your last number a sensibly written article on the subject of smut bladders in wheat, relative to which I beg your permission to make a few remarks. Many years ago an old gentleman communicated to me the result of an experiment which he made relative to smut in wheat: he procured some moderately clean wheat, and divided it into four portions, two of which he washed thoroughly, scrubbing it well with a broom, and changing the water several times, until the water as well as the wheat appeared quite pure, after which in its wet state, he blackened a portion of the wheat thoroughly with smut balls; this sample I call No. 1; he dried the surface of the other portion with new lime, No. 2; the other two portions were not wetted, but one part he smutted over, No. 3; and the other part remained in its original state, No. 4. These four samples of wheat he set by means of the dibble in the middle of a field, on separate ridges adjoining each other; the result at harvest was as follows:—The sample No. 1, produced nearly all smut balls. The sample No. 2, was quite free from smut of any kind. The sample No. 3, produced a large quantity of smut balls, and the wheat was blackened by it, but not so bad as No. 1. The sample No. 4, produced wheat with an occasional ear of smut of wheat, intermixed in a slight degree as is frequently the case. The result of this experiment appears to prove that smut is a disease introduced into the grain through the skin, and is of a similar nature to wheat that the small pox is to the human species, and that it may be, and most frequently is, propagated by inoculation, owing to the sound corn coming into contact with the smut. As a farther proof I may add that during near forty years' observation as a miller, I have generally found that when farmers persisted in setting their old stock of wheat when only a little smutty, the smut has kept increasing till they have changed their stock. I believe that the most smutty wheat which can be produced might be rendered free from smut by frequent washing and scrubbing in several waters, and the only advantage there is in the new slaked lime is, that it operates upon the skin of the grain as a caustic to destroy any virulence which may possibly remain. I know a farmer in this neighbourhood who purchases smutty wheat for seed when a good stock is offered him, not only because he can get it cheaper, but because he is of opinion that it is generally more productive than other wheat, trusting to his own good management in eradicating the disease which he assures his neighbours is only skin deep, although productive of such serious consequences unless removed by some kind of caustic; but this I think, on the whole, a dangerous experiment, for in eradicating the disease there is a danger of killing the patient,

A NORFOLK MILLER.

Sept. 17.

P.S. I recommend the farmers to turn their attention to the corn laws, with a view to the introduction of a fixed duty, rather than the present fictitious system of averages, which can only benefit the large capitalist to the injury of all other classes.

IMPORTATION OF FOREIGN GRAIN AND FLOUR.

[FROM THE HERALD.]

The following letter refers to some former remarks under this head in respect of imports of bread stuffs from the United States, and as coming from a practical source is deserving attention:—

"SIR,—In your paper of this morning the writer of your city article makes some observations upon the importation of bread stuffs from America, which seem to spring from entire ignorance or misapprehension of that important branch of trade. He talks of the impossibility of selecting the American markets in preference to those of the Continent in consequence of their high comparative standard. Having been somewhat engaged in this trade during the past year, I can testify that the American market is decidedly the cheapest of the two. I have purchased wheat at New Orleans, and the same has been done during the whole winter and spring, at 80 cents. per bushel, costing with the high freight of 1s. 4d. per bushel, but 37s. to 38s. per quarter laid down here. Flour has been also bought in large quantities at less than four dollars per barrel, freight about two dollars more, while even at the dearer markets of New York and Philadelphia the article has been selling at less than six dollars, and could be laid down at any port in England at 28s. per barrel. The figure your correspondent gives for the continental markets is much higher than this. Even with the impulse given to the grain markets of the States by the Great Western's news, the price of wheat at Philadelphia only reached 40s. per qr. freight and expenses to England, 5s. 6d. more.

"Were the importation of grain a constant trade, there is little doubt of the United States being our chief market. Their facilities for production and consumption are yearly increasing, the former far beyond their own wants, the latter beyond their own powers. Fitful and uncertain as are their exports of corn to this country, not a farthing of their value is returned in the form of specie, the whole of it goes in that of manufactures. The contrary is observable in our trade in grain with the Continent. The serfs in Poland and Prussia are not consumers of manufactures, like our descendants in the western hemisphere, and the growth of a trade with them must be slow and gradual. Were there any mode of establishing a steady trade with America in grain, under a moderate fixed duty, the farmers in this country would be certain to reap the advantage of a considerable advance in the price of wool, in the growth of which many are largely engaged, and which is so dependent upon American trade for its elevation of depression in value.

"Hoping that you can allow me a corner in your influential journal for these few observations, I remain, sir, yours respectfully,

"A LIVERPOOL MERCHANT.

Tithebarn-street, Liverpool, Sept. 14."

The writer should be quite clear about his own premises before he is so free in charging others with "entire ignorance." It is not denied, nor was it meant to be, that in particular periods of high prices here, wheat and flour might be profitably imported from America; but in the average of years it is incontestable that the prices of corn rule considerably higher in America than in Poland, the north of Germany, and the Black Sea. This being the fact, as fact it is, how will the "Liverpool Merchant" make out his case that, "under a moderate fixed duty," there could be any great general extension of corn imports from the United States, or what he calls "a steady trade" in that commodity with them? In periods of scarcity and high prices there would be, as there are and have been, considerable imports from America; as there have been also from France and from Belgium; but it would be absurd to reason

The Black Torrington estate, consisting of 2,500 acres of land, has been purchased by Lord Ashburton for 30,000l.—*Exeter Times*.

from an isolated case, or from the extraordinary occurrences of one or two years, and so confound and transform the exception into the rule. On the approaching advent of a bad harvest here, always foreseen and speculated upon, recourse is had forthwith to the cheapest corn countries, and especially to those nearest at hand, first. The Baltic ports are therefore first visited, and partially cleared of their stocks. But as prices are enhanced there in the natural order of things with large purchases, and holders are more tenacious as they become advised of rising market, and short produce in England, the speculator next bends his steps to more distant regions, and ransacks the stores of Odessa, if stores there chance to be. He will next resort, to complete his operations, to some of the ports of Asia Minor, with Leghorn and other Italian ports. It is only in default of obtaining the proportion of supplies of which he is in want, or for which he has the means of payment, that he turns his attention to the United States. The reason is evident. His object is not only to sell at the dearest rate, but to buy at the cheapest, because, from the balance results the largest share of profit; and common prudence dictates resort, therefore, in the first instance, to the cheapest and most abundant corn countries. It is only when by his extensive operations the warehouses there have been drained, and prices have advanced so high as to be equalized with those of this country, the market to which he brings his commodity, that he looks elsewhere, and among the rest to the United States. Although corn there is generally dearer of cost, as compared with the parts of the world cited, yet as prices rule so high in England he finds that he can import with a profit still, though a less profit; whilst the American producer, with fair stocks on hand, finds a sale profit also, then that the stocks of the cheap corn countries are exhausted. But it is only under these conditions, and with prices elevated to a certain point here, that American corn can be imported with a profit at all, either to grower or importer. When, for example, the house of Barings commenced their great corn purchases abroad in the year 1838, which were continued last year, although not on so large a scale, they did not despatch their ships in ballast to New York, or Philadelphia, or New Orleans, but to Dantzic, Königsberg, and Memel. They left the lesser people to glean afterwards what is called just a "living" profit, by picking up a few thousand barrels of flour and quarters of wheat in the United States. It is true that the lowness of freight, the certainty of return cargoes, and the general facilities of intercourse, are all so many advantages in favour of the American product, and to the extent serve to reduce the difference of price and the greater cost of production, as between America and the cheap corn regions, but after all they are not considerable enough to equalize them upon balance, as from what has been said may readily be understood. It may safely be assumed, without recurring for the occasion to any calculations in everybody's power, that so far as labour, which enters so materially into the cost, corn can be raised in nearly all the European and Asiatic corn countries before quoted at one-fourth of the outlay required in the United States. The "Liverpool Merchant" may find on consultation of the proper authorities that on an average of years wheat at Salonica, for example, is not one-half the price it shall bear in New York. Doubtless, with the high rates of price now prevailing, and with the bareness of supplies in the north of Europe and elsewhere, corn and flour may be temporarily imported with profit from the United States. It is a misfortune,

we are free to own, that in seasons of deficiency here, the supply cannot be furnished in a larger degree, and more exclusively from the United States, because, as the "merchant" fairly observes, the return value is taken, not in specie, but in manufactures. The reverse is the fact with respect to Poland, where the people are too poor to be profitable consumers, even if the duties on manufactures were not prohibitory. It is not necessary to show the "merchant" how really futile are his sanguine speculations of advantage to the English farmer from a moderate fixed duty on corn, on the plea that they would reap a corresponding profit of a "considerable advance in the price of wool," from the increased demand of America for woollens. But it may be retorted upon him that he seems to be in "entire ignorance" of the fact that the Americans grow wool and make woollen cloths themselves, and that both the growth and the make are on the increase. The breed of sheep in America, writing from memory, is already equal to nearly three-fifths that of this country. The breed here is estimated somewhere about 35,000,000, and in the United States we think at 20,000,000, if not more.

IMPORTANT TO FARMERS.

I beg leave to inform all farmers, whose lands are infected with wire-worm, that I have discovered what I consider to be an effectual method of irradiating those destructive insects.

Having purchased a subsoil plough, for the purpose of breaking up the crust of my sand-land, I commenced using it three years ago, with great success as regards turnips and barley crops. Last winter I subsoil-ploughed three fields, and left a fourth undone, all of which are subject to the worm. My growing crops now show that this ploughing has been a very efficacious means of destroying the worm. The three fields that were subsoil-ploughed are quite free from the worm, and have produced beautiful crops of turnips; while the fourth, I am convinced, would have been nearly all destroyed, had I not employed women and children to go up and down every row, with a knife in one hand, and a pair of scissors in the other, to cut the worms at every injured plant; and by that means I saved eight acres out of ten.

Now I come to the important part of my experience. I commenced with the subsoil plough in January last, and finished in February. My man who used the plough informs me that he found the worms in clusters in the subsoil, in a dormant state; he stopped the plough, and destroyed them in quantities, and I am of opinion that the rooks destroyed the remainder, for there is not a square yard deficient in the three crops of turnips where the plough was used.

I believe the subsoil plough was invented by a Mr. Smith, a Scotchman. I got mine from him. It is made entirely of iron, and calculated to raise the soil from twelve to fourteen inches. I only worked it about four inches, which I consider a sufficient depth. The construction of the plough is very simple, and may be made by any good mechanic.

If any gentleman has a desire to try the experiment, and wishes to obtain a plough, by applying to me, or to Mr. J. West, land-agent of this place, by letter (post-paid), he shall have due attention paid to his order.

JOHN WRIGHT.

Collingham, Notts, Sept. 17, 1840.

ON THE CONSTRUCTION OF TANKS.

[FROM COMMUNICATIONS MADE TO THE SOCIETY BY MRS. DAVIES GILBERT, OF EASTBOURNE, SUSSEX.]

(From the *Journal of the Royal Agricultural Society*.)

These tanks are remarkable for their simplicity, economy, and efficiency, and between thirty and forty of them have already been constructed in Eastbourne and its neighbourhood, and also many in Cornwall, as reservoirs for rain water, in

districts where the drainage of the mines occasions a great deficiency in the springs.

The depth of the tanks is often 12 feet, and the excavation is circular like that of a common draw-well: the diameter, however, of the upper part being one-third greater when the hole is first dug than that of the bottom: the sides are not upright, but have a shelving inclination, which enables labourers, unused to mason-work, to construct them; but where the ground is hard (as in the case of chalk) some labour in making the pits might be saved by their being larger at the bottom than at the top, as is the case with some wells.

After the excavation has been completed, the bottom of the tank is formed of either brick or stone work, or of chalk flints, bedded in with grey lime mortar, and coated with Parker's cement, no *clay* being used in any part of the tank; and the sides are then walled up in the same manner to within about one-third from the top, when the doming commences by circular layers of

bricks, flints, or chalk, resting immediately on the top of the side-walling, the successive courses advancing one-third of their length beyond the previous layers, which are regularly backed in and kept from tilting during the progress of the work by earth. When the doming reaches the surface, and the last course has been laid down, the work will present the following arrangement.

The top must then be secured by slabs of wood, four stones, or bars of iron, or mason-work a foot or two high; a circular opening being left of sufficient size for a bucket, pump, or a man to go down occasionally for the purpose of cleaning the tank. A pump is the most advantageous means of drawing out the manure; but as the pump is liable to be choked by sediment, it should be moveable, and raised, as the soil is deposited at the bottom, by being passed through rings fixed to a post or the nearest building; and if there are several tanks on a farm a single pump may be used for all by turns. These pumps are made of iron, copper, or zinc, by Mr. Turner, of Dorset-street, Fleet-street; and it is essential that a hole be made in the extremity of the handle to fix on a stick of wood, to enable persons standing on the ground to use the handle for the delivery of the liquid into a cask on wheels.

The expence of these tanks depends of course upon the hardness of the ground in digging, and on the kind of material used in casing the bottom and sides of the tank; namely, whether brick, stone, or flints, bedded in the best lime,

mortar, or cement: but, whatever the shape may be, the cost of workmanship paid at Eastbourne has generally been 10s. per 100 feet of surface, for casing the bottom and sides; when brick-work is used, $1\frac{1}{2}$ inch work is sufficient: if flints, from 9 inches to 12 inch work. In digging the last tank of 12 feet deep, on Mrs. Gilbert's estate, two labourers were employed seven days, and eight more days to make a drain for conveying the water from the high-road and casing and doming the tank. The doming was accomplished with the chalk-stones dug out in excavating the tank. One of the tanks at Eastbourne, about 7 feet deep and wide, has served two labourers' families with water for ten years; and the mason-work of this tank was made by three boys of only twelve years of age. One of 12 feet by 7 feet has been found sufficient to afford a constant supply of water to a large family and six horses; this was surrounded by only $4\frac{1}{2}$ inch brick-work, well grouted in with good grey lime mortar, resting solid against the sides. At the Eastbourne Union House, for fourteen parishes, a tank has been made 23 feet deep by 11 feet wide, of the roughest

materials, being only flint-stones; and though they require more mortar than regularly-shaped stones, only 90 bushels of lime were allowed, including two coats of plaster; and the workmanship was executed by the paupers themselves—the only essential points being, that no clay (which worms in time bore through) be used, and that the lime or Parker's cement be good. Labourers' gardens have been watered by the rain which formerly injured the public road, and now turned into a tank surrounded with 9-inch masonry, and the water drawn up by a cast-iron curb. Ponds have been made with equal success on the same principles, dug only $4\frac{1}{2}$ feet below the surface, the excavated portions being added to the sides and covered with pebbles about one foot thick, like a road, embedded in good lime mortar.

Tanks both for soft water and liquid manure are desirable in most farm-yards.*

ON FEEDING SHEEP IN YARDS.

SIR,—Having read in your report of the North-lerton Agricultural Meeting, Mr. John Welbank Childer's remarks on sheep feeding, and having myself practised house-feeding sheep for many years, I beg to say that I perfectly agree with Mr. J. W. Childers as to the extraordinary increase of size and condition as well as economy of food, and what he omits, acquisition of manure, but I think it right to state, for the benefit of those who may be inclined to try the practice, that I have found from long experience that when closely confined in an airy house or shed they did much better, and were less liable to foot-rot, than when allowed to go into a yard, which I attribute to their receiving a sudden chill on going from the warm house into the open air; particularly in bad weather, when on their return to the house, the evaporation from their wet wool causes such intense cold as to check their insensible perspiration, which materially injures their health, causing consumption, cough, and many other diseases. In my opinion, they thrive best in a covered house, on hurdles raised some inches from the ground, lightly littered over, so as to afford dry footing; the litter should be often changed, and the hurdles raised and cleaned under, to prevent any bad smell, and if some sand or fine mould be laid under the hurdles, it will increase the dunghill with the best description of manure. When corn is not very high, one pound of bruised oats or barley to each sheep, or of peas or beans, steeped in strong salt and water, in addition to their potatoes or turnips, greatly accelerates their fattening, and amply repays the expense. They should always have the use of salt, and plenty of clean water to drink.

I remain, Sir, yours,
AN IRISH FARMER.

Should any of your subscribers wish for any further particulars, I shall be happy to afford them the results of above twenty years' experience.

August 17th.

* The Rev. Mr. Rham, in his "Outlines of Flemish Husbandry," page 80, and art. "Dairy," in the Penny Cyclopædia, has recorded the estimation in which liquid manure tanks, or vaulted cisterns under the cow-houses, are held in Belgium.

TOLLS ON LIME USED AS A MANURE.

A pamphlet written by Mr. S. Bailey, Hereford, and published by E. G. Wright, of that town, has lately come under our notice, in which the writer considers the injustice and hurtful tendency of taxing, or in any way adding to the expense of any articles that are used for the purpose of improving the land, and increasing the necessities of life; and makes several very judicious observations on the benefits that would attend, and have attended the abolition of such direct imposts on industry, and concludes with miscellaneous remarks on the situation of cottages, and on the management of turnpike roads. The latter subject has in many places attracted much attention, and we believe, like all similar concerns, good and bad management will be found pretty nearly balanced. The author's idea of publishing the cash accounts of the respective trusts would be attended with satisfaction in certain quarters, and where open straightforward conduct prevails, no objection can be urged; and where that is wanting, publication might induce it. In the scale of a taxation on the eatables and wearables of life, where the necessity exists of raising a revenue from such sources, justice and equity would place home productions in the last rank of being taxed, and in the first of being relieved; and among home productions, a distinction would be made between those that appear of first or secondary importance, or between those that are essential to industry in any shape, and others that are applied to the purposes of luxury and ostentation. All direct imposts create more alarm and dissatisfaction than those which operate indirectly, or which affect by various ways before reaching the original article; and taxes on a manufactured article are much more obnoxious than when imposed on raw materials, either of importation or of home production. Direct imposts on such articles as tiles, bricks, lime, and manures of any kind, are certainly in the first class of relief: in many places tolls are not charged on the latter articles, and in others they yet prevail. The evasions mentioned by the author as being practised by carriers and others in order to evade the heavy payment of tolls, merely shew the shifts employed by human nature in order to avoid oppressions on industry, real or supposed: if the burden could be made light, evasion would not be worth the trouble. On the subject of the corn laws, the author appears a most violent party-man, and sees the results through one focus only; on that point, we have only to say that experience often falsifies many similar predictions on such complicated subjects. The turnpike trusts and private roads of our country are not yet placed on a sound footing of management; local governments will become apathetic when the means of execution must be imposed by the members on themselves. A general comprehensive measure, on a new foundation, is wanted. The author has had ample means of making observations on these points, and brings forward facts for illustration; and in publishing the results of his attention to the subject, he deserves much credit from the agricultural world, and by forwarding petitions and letters to Members of Parliament, means have been adopted of engaging public attention, which we hope will ere long remove such hurtful imposts, and relieve and encourage industry by every possible means.

DISTEMPER IN CATTLE.

Benefit of Tar Water in Fevers, for Cattle as well as the Human Species, in a Letter from the Lord Bishop of Cloyne, to the Rev. Dr. Halls. Published at His Lordship's Desire, on occasion of the present Distemper among the Cattle, and for the general Good of Mankind.—London Magazine, March, 1747.

"To one gallon of fresh tar, pour six gallons of cold water; stir and work them strongly together with a large flat stick for the space of one full hour; let the whole stand six or eight hours that the tar may subside, then scum it, and pour off the water, whereof three gallons warm are to be given the first day, two the second, and one the third day, at equal intervals, the dose not being less than a pint, nor more than a quart, and the beast being all that time and for two or three days after, kept warm and nourished, if it will not eat hay, with a mash or gruel.

"I believe this course will rarely fail of success, having often observed fevers in human kind to be cured in a similar method. But, as in fevers, it often throws out pustules or ulcers on the surface of the body, so in beasts it may be presumed to do the like, which ulcers being anointed with a little tar, will, I doubt not, in a short time, dry up and disappear.

"By these means the lives of infected cattle may be preserved at the expence of a gallon of tar for each. A thing which I repeat and inculcate, not only for the sake of cattle and their owners, but also for the benefit of mankind in general with regard to a fever, which terrible subduer and destroyer of our species I have constantly found to be itself easily subdued by tar water. Nevertheless, though in most other cases I find that the use of this medicine hath generally obtained, yet in this most dangerous and frequent case, where its aid is most wanted, and at the same time most sure, I do not find that the use thereof has equally obtained abroad in the world.

"It grieves me to think that so many thousands of our species should daily perish by a distemper which may be easily cured by a remedy so ready at hand, so easily to take, and so cheap to purchase as tar water, which I never knew to fail, when copiously drank, in any sort of fever. All this I say, after more than an hundred trials, in my own family and neighbourhood.

"But whatever backwardness people may have to try experiments on themselves and their friends, yet it is hoped they may venture to try them on their cattle, and that the success of such trial in fevers of brutes (for a fever it plainly is) may dispose them to probable hopes of the same success in their own species.

"Experiments, I grant, ought to be made with caution, and yet they may be made, and actually are made every day on probable reasons and analogy. Thus, for instance, because I knew that tar water was cordial and diaphoretic, and yet no inflamer, I venture to give it in every stage of the small-pox, though I had never heard before of its being given otherwise than as a preservative against that distemper, and the success answered my expectation.

"If I can but introduce the general use of tar water for this murrain, which is in truth a fever, I flatter myself this may pave the way for its general use in all fevers whatsoever.

"A murrain among cattle hath been sometimes observed to be the forerunner of the plague among men. If that should prove the present case (which God forbid) I would earnestly recommend the copious drinking of warm tar water from the very

first appearance of the symptoms of such plague. I do also recommend it to be tried in like manner against the bite of a mad dog, when other approved medicines are not at hand."

THE CORN LAWS.

(TO THE EDITOR OF THE HERALD.)

MR. EDITOR,—The corn laws are, of course, just now, an interesting subject, and, upon the broad general principle, you have handled your correspondent, "A Constant Reader," well. Will you allow me to grapple with him for a few minutes in detail. The whole of the horror of your "Constant Reader" against the corn laws is compressed in the following passage of his letter:—"As to making it up (the sufficiency of corn bread for this country) by means of our British soils at home, *the thing may be regarded as impossible*. To bring a larger breadth of our home soils into cultivation we must bring a portion of our poor and sterile mountains, bogs, moors, and heaths, into cultivation. This their owners can have little or no inducement to do." It is twenty years this day, since I first visited Lincolnshire. The last stage was from Sleaford to Lincoln. For miles, as far as the eye could reach on the right and left, it was one blank rabbit warren. It is to this day called *Lincoln Heath*, and will probably be called by that name for a century to come. But is it a *heath*? Within five years of the date of my first excursion it was overladen with standing corn. The Earl of Bristol, the Earl of Ripon, Mr. Chaplin, and others leased this rabbit-warren, on easy terms as regards rents, to agricultural capitalists; and the land which seemed incapable of growing any thing but dog-grass, now grows five quarters of wheat, or nine quarters of barley, or twelve quarters of oats per acre! So much for the despair about a "heath." Now, if your "Constant Reader" will just take a walk three miles from Dunstan Pillar, and stand on the brow of a high table land from Potter-Anworh, he will then see what can be done with a *bog*. I will not now trouble you with what I have heard my worthy father-in-law say about the Fens of Lincolnshire, in which he was born and bred, and will die. I will tell you what within my experience I have seen done myself. I have seen corn cut in the Fens of Lincolnshire in boats! There is nothing of that *now*. There is on the spot (and it is impossible to estimate too highly, the *Cincinnatus* sort of feeling which Lord Ripon evinces after retiring from active life) a steam-engine erected, which, by a few days' play in the year, keeps that immense *bog*, stretching on the right of the Witham from Lincoln to Boston, just at the proper moisture the land wants! I will defy any man to show me such crops as are now standing in that *bog*. But I must hasten on, and request your "Constant Reader" to cross the river with me, and hurry to the *Wolds* of Lincolnshire. There he will see what *mountains* will produce, when properly cultivated. Why, Sir, upon that very land, which was not thought worth 5s. an acre, when, like Lincoln-heath, it was perishing for want of cultivation, men live and ride now, as they ought to do, in their carriages. I have that confidence in the industry and the skill of an English farmer that no difficulties of heath, bog, or mountain will, with due protection, prevent him from making this island what it ought to be, "a one and perfect garden overflowing and overgrowing."—Yours,

Aug. 26.

B.

ON GREASE FOR DIMINISHING FRICTION OF MACHINERY.

When every mechanical contrivance has been adopted for the purpose of diminishing the obstruction caused by the attrition of the communicating parts of machinery, it is well known that by the application of unguents the friction may be further removed. Oils are found most suitable for metals, and swines' grease or tallow of any kind when the surfaces are made of wood, and the powder of black lead, has been found very useful in relieving the motion in very small works of wood. Tallow is generally most useful, especially in the case of wood moving upon metal greased with that substance.

In the year 1836, a patent was secured by Mr. Partridge, for the discovery of the following composition for diminishing the friction of the wheels of carriages:—

"To about 20 gallons of clear soft water apply 3 or 4 lbs. of fresh lime, put them into a cask, and stir them well about, then let it stand about 24 hours, or until the water is quite clear, when it may be drawn off as wanted. The lime water should be stirred up every five or six days, that the water may be kept fully impregnated with the lime. To one part or proportion of this solution of lime-water, add one part or proportion of olive oil. These ingredients are to be placed in an open vessel, and whisked, beat, or stirred well together until they are completely blended; or they may be placed in a bottle or jar, and well shaken, until the same effect takes place. The composition of lime-water and oil will then have the consistency and appearance of thick cream, and if the composition made from the above proportions should be found too thick, it may be thinned or reduced in consistency by adding a little more oil; and I would remark that the composition should be well shaken or mixed up before using, and the lime-water should be kept free from sir and as cool as possible.

"For axle-trees and other bearings this composition will be found superior to pure oil, and will not be consumed so rapidly.

"To render this composition more applicable to the lubrication of cogs or teeth of wheels, I prefer whale or other common oil, which may be used in one part or proportion to two parts or proportions of lime-water; and when perfectly commixed as before stated, it is to be added palm oil or tallow, or both, and well rubbed or ground therewith until the composition assumes the appearance of thick paste, when a small quantity of carbonaceous matter, such as plumbago, soot, or black lead may be added, and when incorporated with each other, the composition will be fit for use."

Cows' dung has been found very effectual in the case of carriage wheels set on fire by friction. A very important unguent for the purpose of diminishing the friction of machinery was accidentally discovered in North America in the substance "soap-stone or steatite," pulverized and mixed with oil, tallow, or tar, according to the use to which it is to be applied. It has been used most successfully in all kinds of machinery, and is said to be equally applicable to carriage wheels, and heated machinery has been cooled by it when all other unguents had failed. A motion of 100 revolutions a minute in a wheel turning very heavy rolling machinery, was kept cool and easy without any inconvenience for five weeks without being renewed by the composition.

Soap-stone or steatite, from gr. *στεπ-αρος*. tallow or fat of any kind, is a sub-species of rhomboidal mica—colour grey, greenish white, yellow and reddish white, sometimes marked with spotted and dendritic greyish black delineations, and often veined—occurs massive, disseminated in crusts and uniform, and also in six-sided prisms, in an acutely double six-sided pyramid, and in a rhomboid; the two former are from rock crystal, the latter from calcareous spar. Steatite is internally dull, or feebly glimmering, from a mixture of foreign parts—fracture coarse, splintery, and pass into coarse and fine-grained unoven fragments, angular and blunted—translucent on the edges—streak shining—writes feebly—very sectile—difficultly frangible—feels very greasy—does not adhere to the tongue—sp. gr. 2.4 to 2.6. It loses colour before the blow-pipe and becomes white and hard—fuses with addition, and melts with borax and soda into a greenish slag. Contains:—

Silica.....	44.00
Magnesia.....	44.00
Alumina.....	2.00
Iron.....	7.30
Manganese.....	1.30
Trace of lime and muriatic acid..	

100.80

In some specimens, the portion of magnesia is low as 20, the alumina often wanting, and in some cases as high as 14.

This mineral occurs in small veins that traverse serpentine in all directions, and in feldspar rocks, and also in the metalliferous veins of primitive rocks—it abounds in the serpentine beds in Scotland, in Cornwall, and in Anglesey.

Steatite is much used in the manufacture of porcelains, and like Fullers-earth and indurated tale, it readily absorbs oily and greasy matter, and is hence used for extracting spots of grease from silks and woollen stuffs, and in polishing gypsum, serpentine and marble; when pounded slightly and burnt, it forms the basis of certain cosmetics; writes on glass, and differs from chalk, which leaves no mark, and it is used by glaziers in making plates of glass before they are cut by the diamond. The savages seen on the Orinoco in South America eat steatite, though it absolutely contains no nourishment.

Graphite, another genus of mica, from Gr. *γραφω*, to write, so called from its capability of writing and leaving a mark, is also used in a powdered state for diminishing the friction of machines by being grubbred on the surfaces in a thin stratum, and thus interposed betwixt the parts of attrition.

July 12, 1840.

J. D.

ON LINSEED FOR FEEDING CATTLE.

SIR,—Being convinced that linseed may be used for the feeding of cattle and sheep more profitably than oilcake, could we but know the best mode of preparing it so as not to pass too quickly but be properly digested, I shall be much obliged to any of your readers who can inform me how it can best be prepared for the use of cattle or sheep. Whether by steaming, boiling, or crushing? and if by the latter mode, what mixture must be added to absorb the oil which might be otherwise squeezed out and lost?

I am, yours,

LINSEED.

STATE OF CRIME, 1839.

The following are the leading outlines of returns lately presented to both houses of Parliament, by command of her Majesty, entitled "Criminal Tables for England and Wales, 1839:"—

"The criminal tables for 1839, show a considerable increase in the number of persons committed for trial in that year; the decrease of 2.2 per cent. in 1838, having been followed by an increase amounting to 5.8 per cent., a result which for many years has succeeded any temporary check in the continuous increase of the number of commitments. The increase is spread over 25 English and 9 Welsh counties, and amounts to 2,627 persons, or 12.5 per cent.; while the decrease extends only to 14 English and 3 Welsh counties, and amounts to 671 persons or 11.1 per cent., leaving the net increase 1,356 persons.

"The following calculation will show the proportionate increase or decrease in each of the classes of crime during the last three years:—

Class.	1837.	1838.	1839.
1st Offences against the person	12.1 dec.	8.1 inc.	8.1 inc.
2nd Offences against property, committed with violence	6.8 inc.	9.1 inc.	6.9 dec.
3rd Offences against property, committed without violence ..	18.8 inc.	3.3 dec.	5.3 dec.
4th Malicious offences against property ..	32.1 dec.	21.9 dec.	17.9 dec.
5th Forgery, and offences against the currency	27.0 inc.	10.3 inc.	13.3 dec.
6th Other offences, not included in the above classes	1.0 inc.	20.4 dec.	47.3 inc.

"The principal increase in the last year, in the 1st class, has fallen chiefly on the lighter offences of assaults and assaults on peace officers. There is an increase in the attempts to murder; but murder itself, and manslaughter have decreased. In the 2d class, burglary, house, shop, and counting-house breaking have decreased; robbery has slightly increased. In the 3d class, which includes nearly four-fifths of the whole number of commitments, all those offences of most frequent commission have increased—such as larceny, larceny in dwelling-houses, from the person, and by servants (which latter offence has increased 20 per cent. last year, and has been progressively increasing for several years) embezzlement, fraud, and receiving stolen goods; horse, sheep, and cattle stealing have decreased. In the 4th class the increase has been general, though, compared with the preceding five years, the numbers are far below the average. The 5th class shows a decrease, which has been very marked, in coining, and having in possession coining implements; while, at the same time, the increase for uttering forged Bank of England notes, has been equally remarkable, though the commitments for these offences are so few that the proportion is doubled by the addition of two or three offenders. The 6th class has considerably increased, and this may, in a great measure, be attributed to the political offences connected with Chartism, which are placed in this class under the head riot, sedition, &c. But the Chartist offences, for trial at the Monmouth Special Commission, and many other prosecutions of this description, do not find a place in these tables. They will be inserted in the tables for 1840, in which year they remained for trial.

"The great amelioration of the criminal code, which was effected by the acts of the 1st Victoria, is more clearly exhibited by the tables of 1839 than by the tables of the preceding year, those acts having come more generally into operation. The capital convictions amount to 54 only, a number considerably less than the average of executions 10 years previously.

"The acts of the 1st Vic. have also had a very beneficial effect upon the result of prosecutions; juries being in all cases less unwilling to convict when they know that capital punishment will not follow.

"Though there has been, for many years, a great progressive increase in the number of commitments and convictions, the increase in the number sentenced to transportation has been beyond all proportion to the general increase. This great increase in the number of transports immediately followed the Act of the 7 and 8 Geo. IV., c. 28, and arose out of an enactment in that statute, augmenting the punishment to which the prisoners were liable, on the proof of a previous conviction for felony. The greater severity in the punishments, which was consequent upon this enactment, is at once obvious on a reference to the numbers sentenced. The act was passed in 1827; the average numbers sentenced to transportation in the three preceding and the three following years, were as follows:—

	Aver. of 1824-5-6.	Aver. of 1828-9-30
Numbers sentenced to transportation for life.....	125	373
Ditto ditto for 14 years ..	140	619
Ditto ditto for all periods .	1884	3168

"This sudden increase was maintained in the succeeding years, and gradually progressed with the general increase of commitments, so that the average of the last six years amounts to 3746. The acts of the 1st Victoria have, however, tended to reduce the frequency and severity of this sentence. The numbers sentenced to transportation, or whose sentences were commuted to that punishment, which in the four years preceding those acts averaged 4154 annually, were, in the last year, 3699 only, and the severity of the periods of transportation were at the same time reduced in a much greater degree.

"The calculations which have for several years been made as to the ages and degrees of instruction of criminals, exhibit a very great uniformity of result. During the last four years nearly 41 per cent. of the criminals do not exceed 21 years of age; and in the next division of the tables, those not exceeding 30 years are included 71 per cent. This would give criminals but a short career, and may in a great measure be attributed to the numbers annually removed from the country by transportation.

Degree of instruction.	1839.	1838.	1837.	1836.
Unable to read and write	33.53	34.40	35.85	33.52
Able to read and write imperfectly	53.48	53.41	52.08	52.33
Able to read and write well	10.07	9.77	9.46	10.56
Instruction superior to reading and writing well	0.32	0.34	0.43	0.91
Instruction could not be ascertained.....	2.60	2.08	2.18	2.68

"With respect to the sexes of criminals, it is worthy of remark, that for several years the proportion of females has been increasing. Comparing the number of males and females, the centesimal proportion of the latter was, in 1834, 18.8; in 1835, 20.0; in 1836 and 1837 it was the same, 21.6 (though the fraction, if carried further, still shows a small increase in 1837); in 1838, 22.1; and in 1839, 23.2,

"Home Office, Whitehall, June 11, 1840.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—I should feel greatly obliged to some experienced Sheep Breeder who would give information through the medium of the *Mark Lane Express*, as to what is the best cure for sheep that lose their eud.

Yours respectfully,

A NORTH DERBYSHIRE FARMER.

ENGLAND IN THE SEVENTEENTH CENTURY.

(FROM BLACKWOOD'S MAGAZINE.)

The following curious particulars as to the state of England in the 17th century are collected from a little book called "*Anglia Rotata*," by Edward Chamberlayne, LL.D., R.S.S., dedicated to the Lord Treasurer Danby:—

"The English are generally great flesh eaters, although, by the nearness of the sea, and abundance of rivers and fish ponds, there is no want of fish. In former times, their table was, in many places, covered four times a day; they had breakfasts, dinners, beverages, and suppers, and every where set dinners and suppers, until the time of the late troubles; wherein many eminent families being much impoverished, a custom was taken up by some of the nobility and gentry, of eating a more plentiful dinner, but no supper; as, on the contrary, the Romans and Jews anciently, and the hotter climates at this day have little or no dinners, but set suppers.

"Feasting, also, is not so common and profuse as anciently. Anciently, at a call of sergeants-at-law, each sergeant (saith Fortescue) spent 1,600 crowns in feasting, which in those days was more than 16,000 now.

"Since the late rebellion, England hath abounded in variety of drinks (as it did lately in variety of religions) above any nation in Europe. Besides all sorts of the best wines from Spain, France, Italy, Germany, and Grecia, there are sold in London above 30 sorts of other drinks, as brandy, coffee, chocolate, tee, aromatic, mum, sider, perry, beer, ale, many sorts of ales, very different as cock, stepony, &c.; a piece of wantonness whereof none of our ancestors were ever guilty.

"The ancient English vices were gluttony, pride in apparel, and excess of drinking. Some persons, and those of quality, may not be safely visited in an afternoon, without running the hazard of excessive drinking of healths; and in some places it is esteemed an excellent piece of wit to make a man drunk; for which purpose some swilling insipid trencher buffoon is always at hand.

"However, it may be truly affirmed, that at present there is generally less excess of drinking (especially about London since the use of coffee, &c.) than heretofore. Duelling, so common heretofore, is now almost laid aside here as well as in France.

"Houses in cities, that were made formerly usually of wood, are now built of good stone or brick, and covered with slate or tile; the rooms within, formerly wainscoted, were then hung with tapestry, or other convenient stuff; and all ceiled with plaster, excellent against the rage of fire, against the cold, and to hinder the passage of all dust and noise. The modern buildings were far more slight, and of less continuance than the ancient. The houses of the nobles and rich were abundantly furnished with pewter, brass, fine linen, and plate; the mean mechanics and ordinary husbandman wanted not silver spoons, or some silver cups in their houses. The windows every where glazed, not made of paper or wood, as is usual in Italy and Spain. Chimneys in most places, and no stoves, although the far more southern parts of Germany could hardly subsist in the winter without them.

"Anciently the fee expected by a sergeant from his client, for advice given at his chamber, or for pleading in any court of judicature, was no more than 20s., and the fee of a barrister 10s.; but at present it is become almost ordinary to give some sergeants 10l., and some 20l., and to a barrister half as much at the hearing of any considerable cause; whereby it comes to pass that some lawyers in one year gain in fees 3,000l., and some 4,000l.; and, in a few years, purchase estates fit for lords, and sometimes live to see themselves advanced to be peers of the realm.

"Anciently the usual fee of a doctor of physic was 20s., and one that had not taken that degree 10s.; at present there is, no certain rule, but some that are

eminent have received in fees yearly 2,000l. or 3,000l., and purchased great estates, which in other countries is very rare.

"The income of the Queen Dowager was 60,000l. a year; the lords of the bedchamber had 1,000l. a year; and the officers of the household seem to have been paid very much according to the present scale."

The following account of the Post-office is curious, at a time when we have seen its revenues amount to a million and a half of pounds sterling—of which, it seems, the Exchequer could spare one million!

"Though the number of letters-missive in England were not at all considerable in our ancestors' days, yet it is now so prodigiously great (since the meanest people have generally learnt to write), that this office is farmed for 30,000l. a year. A letter, containing a whole sheet of paper, is conveyed 80 miles for 2d.; two sheets, 4d.; and an ounce of letters but 8d.: and that in so short a time by night as well as by day, that every 24 hours the post goes 120 miles; and in five days an answer of a letter may be had from a place 300 miles distant from the writer."

Travelling, too, had improved:—

"There is of late such an admirable commodiousness both for men and women of better rank, to travel from London to almost any great town of England, that the like hath not been known in the world, and that is by stage coaches, wherein one may be transported to any place, sheltered from foul weather and from foul ways, free from endamaging one's health or body by hard joggling or over-violent motion, and this not only at a low price, as about a shilling for every five miles, but with such velocity and speed, as that the posts in some foreign countries make not more miles in a day; for the stage coaches, called flying coaches, make 40 or 50 miles in a day (!) as from London to Oxford or Cambridge, and that in the space of 12 hours, not counting the time for dining; setting forth not too early, nor coming in too late."

TO THE EDITOR.

Sir,—In the Farmer's Magazine for August, page 101, is a plan of treatment for the disease termed "diarrhœa," which form, by being wrongly worded, may lead those who follow the advice into a dangerous error.

The receipt says, "As soon as the disease is ascertained, use gentle bleedings and mild purgatives, such as prepared chalk, opium, catechu, &c." The words "*such as*," together with the omission of the name of the mild aperient, convey the mistake; chalk, opium, and catechu, so far from being purgatives, are powerful astringents, and would, if used as recommended, do much mischief, by prematurely checking the purging. With all due deference to the compiler of the paragraph, he must allow me to alter it thus:—as soon as the disease is ascertained, use gentle bleeding and mild purgatives, such as powder of rhubarb or castor oil, after the proper action of which, give the form of prepared chalk, &c., in the proportions prescribed. I hope you will pardon the liberty I take in pointing out this error, but now that your magazine is spreading its opinions far and wide, and is become one of the regularly admitted periodicals into the farmer's clubs, it would not be safe to allow so glaring a mistake to pass unnoticed.

I had not time last week or I should have alluded to the receipt of M. O. for the foot-rot; this Mr. Gall has very properly done in your paper of to-day. Persons giving recipes, medical forms especially, cannot be too careful, as what is seen in print is too often believed and tried without farther enquiry; they ought at least to know the legitimate names of the drugs they prescribe, or irreparable injury may result from following up their well-intentioned advice.

The case in point requires more than an ordinary degree of caution; the most powerful preparation of mercury (the strongest poison and caustic in the whole list of medicines,) and the mildest being both white, whilst calomel, the intermediate form, is equally so; the inert metal is of itself of a silvery lustre. Again, in many places "white arsenic" is as often asked for under the name of "white mercury" as under its more lawful cognomen.

"A Young Gardener," date, Ipswich, 19th Aug., must seek further for the cause of the injury to his potato plants, the "black-winged ants." Query, were they not black ants with transparent wings?—were feeding on some small parasitical insect, the real cause of their decay. The ants, probably male and female, for both have wings at this season, were ridding him of the enemy. The ants, indigenous to our soil, are considered harmless, rarely feeding on anything save animal food, or the saccharine excrements of some of the smaller insects.

Your obedient servant,

Stoke-ferris, Norfolk, 25th August.

P.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—Your paper may be made extremely useful in aid of the objects of the Royal Agricultural Society, if practical farmers could be in general induced to communicate what strikes them as new, in relation to those objects, and though the communications may not appear of great utility, yet many of them would probably lead to something useful in the minds of some readers. The history of the progress of scientific knowledge, is full of instances of great effects from small gleanings; and men of the greatest ability have not disdained to obtain knowledge, or constantly try to obtain it, even from the humblest individuals.

When I became a practical farmer, Swedish turnips were unknown; heavy crops of other sorts of turnips were grown, and found very precarious food for cattle and sheep by the frosts, which frequently swept them away, and thereby caused great distress.

In those days sowing turnips to be eaten in parts by cattle or sheep in succession, was much disregarded, and instead of a regular supply of nutritious food, the animals had often to be kept on dry coarse woolly turnips (pined in the midst of plenty) on which they fattened slowly, if at all. The tares for summer eating, were not then sown in crops to eat in succession, but altogether; and often from being coarse, much wasted: they were also generally sown on wheat stubbles, foul and poor, the produce of course small. I cannot in the usual space of a letter, notice the immense improvements amongst good farmers, during the last fifty years in draining; course of cropping with prospective previous years preparations, supporting well a large proportion of animals, obtaining and economizing a large stock of manure, with good cleaning of the land from weeds, &c. &c., otherwise than briefly. But the improvement has been gradually progressive, and the experimental farms of bad farmers have been conducive to this effect.

I remain, Sir, yours respectfully,

Nottingham, July 10.

S. R.

ANIMALCULÆ IN CHALK.

Recent examinations of the constitution of chalk and calcareous rocks have discovered that the smallest grains of chalk consist of regular elliptical particles, possessing a crystalline aspect, and that the strata in the north and south of Europe present two different structures, one organic, consisting of microscopical shells, the other inorganic, with a granular slaty disposition and regular elliptical structure. By mixing Canada balsam, by the assistance of heat, with dry chalk, in a fine state of division, Prof. Ehrenberg found in chalk an immense number of microscopical animalculæ: hitherto unknown, varying in size from $\frac{1}{4}$ to $\frac{3}{88}$ of a line. A cubic inch contained upwards of a million of them, and consequently a pound weight of chalk contains above 10,000,000 of the animalculæ. In the white and yellow chalks of the north of Europe, the mineral particles equal or exceed in quantity, the organic matter. But the nautilites greatly predominate in the chalks of southern Europe, and the formation is wholly composed of them, and besides the calcareous nautilites, siliceous infusoria have been found in the chalk of Gravesend. Marls belonging to the chalk formation, and forming ranges of hills, contain siliceous infusoria mixed with the nautilites, which have also been observed in several kinds of polishing slates, some of which are reckoned a tertiary marl formation. The same characteristic animalculæ of the chalk have been observed in the limestone containing nummulites of Cairo, and of the pyramids of Gizeh. Many conservee, sponges, and fuci have been observed, and as many as 71 species of microscopical animals supplied with siliceous and calcareous shells in the chalk, and also several larger shells, about $\frac{1}{4}$ of a line in size. The genera "Textularia and Rotalia" are most predominant. There have been found 7 genera and 22 species of microscopical nautilites and nummulites, shells of the genus Cypris, &c., and 40 species belonging to 14 genera of siliceous infusoria, including the 8 already described, which were contained in the flint, and also 5 species of plants containing silica. Sponges and peculiar nautilites have been found in the flint of the Jura limestone of Cracow, and the shells of the chalk in the kidney-shaped masses found in the strata under the chalk at Cambridge. From these researches it has been inferred, that in all probability the strata of the chalks of Europe are the product of microscopical animalcules, most of them invisible to the naked eye, and that the microscopical nautilites are the characteristic constituents of the chalk formation. Fossil animalcules and the shells in a state of superior preservation, distinguish the chalks of the south of Europe, and the fossils contained in many chalks and nummulitic limestones show that they belong to the secondary formation rather than the tertiary, to which they have usually been assigned. The chalks of the south of Europe contain no flints, while the northern strata possess many horizontal regular beds, separated from each other from one to six feet; but no siliceous infusoria are found, which are so abundant in the southern formations. It is possible that the flints may have been formed by the gradual conversion of the beds of siliceous infusoria, and this change in connexion with the greater quantity of mineral particles, resulting from the decomposition of the nautilites, would appear to assign a more ancient epoch for the formation of the northern chalk.

SHEEP BREEDING.

(FOR THE CARLISE PATRIOT.)

"When a race of animals have possessed in a great degree, through several generations, the properties which it is our object to obtain, their progeny are said to be well bred, and their stock may be relied on; and it cannot be doubted that any breed may be improved in the same manner."—*Nir John Sinclair.*

I think that every person who obtrudes his opinion on society, thereby, in some measure, becomes a public servant, and amenable to public opinion. As such I respectfully bow to the suggestions of others, who say it is proper that I should write one more letter on this subject, and then collect the whole into a more permanent form. In the preceding letters, which the public have so kindly received, I have never aimed at display, or striven for mastery, but simply endeavoured to state and elicit the truth, hoping that where I was correct I should be confirmed, and where in error indulgently corrected. It is well known that if, from some unknown or accidental cause, an individual is produced possessing some unusual peculiarities, his progeny, to a certain degree, will probably possess the same, and if a male and female are selected with those peculiarities, and care is afterwards taken to exclude all who have it not, a new and permanent breed may be established. Just so did the late Mr. Bakewell produce and retain the new Leicesters, and just so are produced the justly admired new Oxford. I was at Mr. Hewer's (Gloucestershire) ram sale on the 22d. ult., and saw him really refuse 110*l.* for one sheep; and he, too, must now become an in and in breeder, or he can have no warranty in his sheep, or permanent hold on public approbation. It is also equally clear that climate, soil, and food will effect considerable change in the form and quality both of wool and flesh of every breed. In the few remaining observations I have to make, I hope to win public attention and approval; yet, after all, a writer has his own views, will pursue his own course, and must abide the consequences. And under this responsibility I deliberately adopt the observation that that which enables the sheep-master, not only to modify the character of his flock, but to change it altogether—the magician's wand by means of which he may summon into life whatever form and mould he pleases, viz., the principle of judicious selection, (not necessarily crossing,) for like will beget like, therefore I again urge it, breed only from such as possess the qualities the most desired; and, fortunately, prejudices are fast disappearing before the diffusion of truth, and those who have been accustomed to despise all knowledge but what they gained by their own experience, are beginning to discover this to be a very dilatory mode of acquiring it. I therefore now most anxiously press upon the serious attention of the noble president and members of the British Agricultural Society and stock masters generally, to award prizes and encouragement to such animals only as have right form and constitution, not estimated by comeliness of mould or mountains of fat, and, above all, avoid being led away by capricious fashion, for remember there virtually is but one standard of excellence, and never can be two. Do not be satisfied with hearing your neighbours cry, lo here, and lo there, this is a good sheep, or that is a fine sheep. If he has not anatomical perfection he will lack constitution, and his progeny, even to the third and fourth generation, will be amiss and prone to disease. Are we

not continually hearing that Mr. A. has had bad luck with his lambs, and that Mr. B.'s tegs do not thrive, or that Mr. C.'s ewes are falling off? And we indolently attributing all this to season, pasturage, or faulty shepherding, without ever asking for the truth, which is here, and in a nutshell. What rams have Messrs. A. B. and C. been using for the last three or four years? Would you employ as your builder a man who cannot map a roof or draw a staircase? Will he ever shine as a marine architect who can carelessly regard the skeleton and sailing qualities of the herring? Neither will I encourage the sheep husbandry of him who thinks lightly of the anatomy of the animal. You may contend till doomsday about points, weight, and wool, there is but one form, be it light or heavy, but one internal structure and formation that admit of health, stamina, and constitution; but those obvious and all important facts are sadly underrated by many of our top-breeders. Neither can I sufficiently deprecate the unpatriotic, unhealthy, and uneconomical practice of artificial feeding. Close confinement and artificial food injures the health of all animals, and is hurtful in an especial manner to sheep, which, by nature are of a roving disposition and exceedingly fond of liberty. Let us see what a perverted mode of feeding has done for us in the quality of wool.

Mr. Nottage states, of the Western Down sheep, that he used to get one-eighth part of the finest English wool from each fleece, but now the quantity is so small that he does not take the trouble to throw it out, he does not set a basket for it at all. Mr. Sutcliffe says that thirty years ago there was in some South Down flocks nearly as good wool grown as the fine German that now comes into the country. Mr. Varley states that he used, in sorting his wool, to make ten sorts, but now the quality is getting so low that he has quite lost the two upper castes. Mr. Fison states of the Norfolks, that in 1780, 420*lbs.* of clothing wool would produce 200*lbs.* prime; in 1830 it would produce only 14*lbs.*

These are some of the deleterious effects on the fleece of artificial feeding and coarse breeding; the wool and the flesh is sacrificed to accommodate the tallow-chandler. Therefore, to the top-master who persists in artificially feeding his breeding animals, I would say, lay not the flattering unction to your soul, that you can long pass for an honourable man in entailing on society, stealthily, but surely, a jumbled race of animals that were erroneously propagated, deceptively disposed of, and will be sickly and unprofitable in their progeny. A top so bred and so fed, when reduced to ordinary food, under ordinary circumstances, will become disarranged and inept in himself, and unhealthy and degenerate in his offspring, with foundation for the long train of diseases the species are liable to. While a sheep with a correct skeleton, where the lungs have free space to oxygenize the blood on which vitality depends, and all the viscera unconfined and unobstructed, that *all* the food be assimilated and converted into healthy chyle, then we are sure of a vigorous, healthy, and well developed animal, and which, (especially if bred according to nature,) when making up for the shambles, and placed side by side with one of heterogeneous breed, incorrect form, and pampered constitution, will fatten on less food, and in two-thirds of the time, and arrive at greater weight, or, if allowed in food, will yield finer meat, more profit to the feeder, more credit to the butcher, and satisfaction to the consumer. And be-

fore I close this letter I would observe to all of you who take the trouble to think for yourselves, be not deceived with the vain idea that because you have got a lump of fat that you therefore have secured a good or even a healthy sheep. Be assured that, without pedigree, without form, or without constitution, you will never pass for a scientific or a profitable stockmaster. I am now about to turn my thoughts to some other division of husbandry, and for which I crave a like indulgence. I am, Sir, yours respectfully,

PRACTICAL.

TALLOW AND THE ANGLO-RUSSIAN TRADE.

TO THE MANUFACTURERS OF CANDLES AND SOAP THROUGHOUT THE UNITED KINGDOM.

GENTLEMEN,—I beg to call your attention to a paragraph which appeared in a leading Paris journal, the *Journal des Débats*, a short time back. In allusion to our alliance with Russia, and addressing England, it says:—

“Do not deceive yourselves. Russia has her eyes constantly fixed on Constantinople. There lies the question of life and death for you—for you, we say, because you are a thousand times more interested in it than we are. Are we, in the east, your rivals and neighbours? Who pays and urges Persia to march her armies against you and invade your Indian possessions? Who maintains pretenders to your principalities? Who is secretly driving to revolt their native populations? Who excites China? Who is advancing against you through Central Asia? Russia, Russia! Whatever side you turn to in the eastern world, whence you derive both your power and wealth, you everywhere meet before you that silent, inevitable, and eternal barrier. And yet you are now taking Russia by the hand to lead her to Constantinople. History will not believe it.” And remarks again, “It would appear the misfortune of Great Britain to be constantly fostering the pretensions of Russia, no less through her counsels than by her commerce and her wealth.”

The article has immediate reference to the affairs of the east, but is pregnant of matter which, in the first and highest degree, is important to you. The opinion, as expressed above, is every day gaining ground among the people of this country, and I may venture to assert that there is scarcely one man interested, however remotely, in the Russian trade, who has not seen and felt the baneful influence exercised by the traders of that nation over our own.

It is not enough that we take large quantities of produce from Russia annually—that every article of export to Great Britain forms the subject of *monopoly in her own markets*; but after these commodities are brought to England, *Russian subjects* are waiting to receive them, and ready to practise the same system of *exclusion* among ourselves.

I have selected tallow as the most important article of her produce, and as that which most materially concerns you; and I would ask of any member of the trade whether the extravagant prices at which the Russian monopolists have kept it during the last three or four seasons, have not only prevented the fair trader from getting a profit by his labour, but in many instances occasioned loss and ruin?

Precisely the same is it with hemp, flax, linseed, and other exports to our country.

It is right, therefore, that the people of England should now understand the state of the trade I allude to.

Intelligence, striking and important, is brought by every foreign mail, and in the theatre of the east who can say what tragedy may not be acted? We may be hugged to closer and more intimate alli-

ance with the Muscovites. We may be destined to immediate hostilities against them. But whatever may happen, and under whatever guise we find them, we should, at all events, be well acquainted with the state and value of our commerce, that when the time comes we may neither undervalue, nor regret over much, the traffic we should lose. But if I state broadly, that from the Russians we derive no fair dealing save that negative justice which is forced from them, you may well ask by what means her acts should be met and counterbalanced? Gentlemen, they are in your own power, safe, legitimate, and certain.

In the course of the ensuing month of September, tallow to the amount of 60,000 casks at least will have arrived from St. Petersburg, and in October, or perhaps ere then, 100,000 casks more, the bulk of which enormous quantity will come consigned to one or two men, *natives of Russia*, who scarcely speaking English to make themselves understood, confidently calculate on your credulity, and that this year, as heretofore, you will rush in a body to relieve them at high prices of their adventure.

If you do so, you deserve to lose the profit that it is the object of this letter to preserve for your own use. Remain quiet—“bide your time,” which be assured will come; purchase one cask only at the high price for ten at the fair value, and believe me a variety of little items, rent, warehousing, charges, interest of money, &c., will soon tell a tale, and *prove to you* your power.

And why should it be otherwise? What is there in the present state of England, in the condition of her pastures, and the value and number of her stock, to justify an apprehension of scarcity of tallow? Scarcity, after the addition in this year, of a million to the number of sheep! After an unusually fine season, dry, and luxuriant, are we to fear scarcity when plenty is about us? In London alone there remains over from last season not less than 13,000 casks; this year's import from St. Petersburg, 160,000; from Odessa and other places, 8,000; making a total of 181,000 casks of foreign tallow, each weighing nine cwt., exclusive of an enormous produce of home fat, on which produce so much in every year depends.

Independent of these masses there are warehoused at Buenos Ayres about 6,000 tons, some say 10,000 tons, equal to from 20,000 to 30,000 casks of South American tallow, only waiting the raising of the French blockade to arrive here: and so confident are the merchants trading to that country that the blockade will shortly end, that they have despatched 10 to 12 large ships in ballast to bring it.

Thus much, then, for the trade as depending upon Russian tallow, our own home produce, and the supply from South America. But there is another circumstance of immeasurable importance which bears upon the question,—and whether this new feature is more remarkable in its effect upon the immediate subject I am discussing, or more interesting in its appearance in another view, remains to be seen,—I allude to the produce of Africa, that cradle of slavery, whose occupants have baffled successive ages to civilise, and on whom the people of this happy land have lavished their sympathy and their treasure to raise at least somewhat from this abject state; yet, on the one hand, we encourage the exports of tallow from Russia, we pay homage to the two or three commercial despots who rule over it here, we give them millions of pounds sterling per annum more than the value of their goods, receiving in return a scornful distrust and an hostility to our trade and our settlements, of which one day the full force will be discovered; and on the other hand, there is that country which all classes here would benefit and foster, over whose interests even royalty has condescended to preside, and for whose welfare but one aspiration and prayer prevails. From that country even in its present state of misery, will arrive during the next six months 20,000 tons of palm oil, and why should not that quantity be increased? The demand: let its present value determine that. Its effect upon Russian trade? Are we bound to consider it, when the civilization of Africa is

in the balance? And let the abolitionist of slavery be assured that the encouragement of African trade is the encouragement of African civilisation; and coeval with that will be the downfall of slavery and the slave trade. To you I need say nothing as to the value of palm oil as a substitute. I need not remark upon the effect so large a quantity as 20,000 tons will produce, in addition to the extraordinary quantity of tallow this season. I repeat to you, gentlemen, the game is in your own hands; you, the manufacturers, have but to practice guarded patience, and tallow will speedily fall to that price below which no one interested would wish to depress it. At a future period, I will take the other articles of Russian produce, and show also in our trade with her how little of reciprocity we meet with from the haughty Czar.

A MANUFACTURER.

ON THE CAUSE OF THE INFERIORITY OF STREET MANURE FOR THE RAISING OF POTATOES.

By HENRY R. MADDEN, Esq. M.D., Penicjik.

(Premium of Twenty Sovereigns given by the Highland Society.)

In consequence of a notice having been published by the Highland and Agricultural Society, in reference to some facts communicated to them respecting the inferiority of the street manure of Edinburgh for the raising of potatoes, I have been induced to make some inquiries into the subject, the results of which I beg now to lay before my readers.

The subject is undoubtedly one of uncommon interest, for several reasons, among which stands pre-eminent the one mentioned in the Society's notification above referred to, namely, its tendency to throw some light upon the physiology of vegetable nutrition. Prior, however, to my detailing the experiments which I have performed in connection with this subject, I would beg to make a few introductory observations upon such examinations in general, with a view, not merely to determine the various points to be attended to, but likewise to shew the extreme difficulty of the subject, and consequently the many precautions necessary in order to render them of any practical utility.

As regards the various circumstances which should particularly engage the attention of the scientific investigator, it may be observed generally, that, from the present extremely imperfect state of this branch of vegetable physiology, the more numerous they are, the more trustworthy will be the conclusions which are drawn from their consideration; for although, as the science advances, many of these may be proved to be of no consequence, still, in its present state, the more minutely each circumstance is noticed the better, as it is always preferable to err on the side of too minute enquiry, than to run the risk of drawing false conclusions, from the omission of some circumstances, which might appear trifling at the time, but subsequently prove to be of vital importance to the establishment of the truth.

The connection existing between any particular manure and any particular plant, may be considered, in this country at least, as a perfectly new investigation; not that I mean to assert that no person has endeavoured to find out the best manure

for each particular crop, for, in a practical point of view, there is no subject which has been so carefully examined by judicious farmers. *Scientifically*, however, I do not know of any attempt made to explain the reason why some manures succeed better than others for the raising of certain crops. In this respect, therefore, I may be said to be treading upon a new path, and I trust that my readers will deal leniently with my attempt.

With regard to the difficulties attending such an examination but little need be said, as they must be obvious to all those who have paid any attention whatever to physiological botany. For example, all that is at present known in reference to the nutrition of plants is, that they are capable of extracting various organic matters from the soil by means of their roots, and likewise that they derive nourishment by their leaves absorbing different gases from the air, which are capable of being converted into nutriment. Beyond this, little or nothing is known. Sir Humphrey Davy, indeed, appears to have proved that plants could only absorb *fluids* by their roots, and hence argued that all their food must be soluble in water; but still there are many anomalies here which have never been satisfactorily explained, as, for example, the existence of *insoluble* matters in plants, &c. Again, Berzelius has endeavoured to explain the steps of the process of putrefaction as it occurs in soil, and Thier of Berlin, and Theodore de Saussure of Paris, have followed these out, so as to explain the appearances observed in soils; here also, however, the data are scarcely sufficiently numerous to render the conclusions altogether worthy of being admitted as established laws. By far the greatest difficulty, and, in fact, one which appears to me altogether insuperable, is, that the whole process of absorption by the roots is entirely concealed from our view, and no means can be used to render it visible, which do not at the same time place the plants in very unnatural situations; and, consequently, the results obtained in such cases are certainly extremely liable to lead to erroneous conclusions.

Lastly, in reference to the present investigation, I shall endeavour to point out the probable reasons why street manure is less useful than that obtained from dairies and stables for the raising of potatoes, without attempting to throw any doubt upon the statement that such is really the case; although it would be by no means difficult to shew that the most minute attention to every circumstance of soil, situation, &c., must have been accurately attended to, in order that the statement should be considered as *absolutely* proved. But, since I have no means of ascertaining whether such has been the case or not, I must of course consider the statement to have been so satisfactorily proved to the Society, that no reasonable doubt can be entertained of its *absolute* truth.

1. It is my object in this place to state the different steps of the following investigation, in order that the arguments there laid down may be more fully understood.

The circumstances to which I have paid most particular attention are the following:

1st. I have performed a careful and minute chemical analysis of the three manures in question, with a view not merely of determining their actual constitution, but likewise to institute, as far as possible, a comparison between them.

2dly, I have analysed with equal care the potato, for the purpose of seeing what connection exists between it and these manures.

3dly, I have also examined the composition of the turnip, for two reasons, viz. (1.), to ascertain its connection with the manures in question (this being a crop for which it is stated that the street manure is equal to the other two); and (2.) to see in what respects it differs from the potato.

4thly, (And here the chemical investigation ceases) I have examined the habits of the two plants in question, and compared these with the different circumstances exhibited by the three manures in regard to putrefaction, mechanical form, &c. This it appears to me is all that can be accomplished by a scientific investigation, in the present position of the statement; but before concluding, I shall endeavour to point out a few circumstances which I think well merit the attention of those engaged in the cultivation of these crops; for there can be no doubt that, in order to render any examination of this kind perfect, theory and practice must go hand in hand, and mutually corroborate each other.

If, before proceeding to detail the steps of the process used in analysing the three manures, it will be necessary to explain the reasonings upon which the method was founded.

In the *first* place, it is evident that a perfectly accurate analysis was not required, on account of the impossibility of instituting any accurate comparison between the three, founded upon minute proportional differences. For it is obvious that, from the very varying constitution of such a complex substance as manure, it is utterly impossible that any analysis can serve to denote the *proportional* constitution of the species, but can merely apply to the *individual*; nay more, in the case of the mass being considerable, an analysis of one hundred grains can, properly speaking, denote *accurately* the constitution of no other one hundred grains in the whole mass, because it is evident that so small a quantity, unless carefully selected, may consist of a few only of the many ingredients which constitute the entire mass. Considerations such as these at once must prove the inutility of performing an *accurate proportional* analysis of manure, for the purpose of comparing one or more species with each other.

It may, however, be argued, that all these difficulties could be avoided by analysing a large mass, say several pounds, of the specimen, in place of trusting to the results obtained from one hundred grains. But a little reflection will prove that, in point of fact, all the objections apply here, as elsewhere, with equal force. For, taking it for granted that such an analysis were performed, —which, however, is far more difficult than one might at first imagine, especially if it be desired to render it by any means accurate,—still when a comparison was about to be made, would not the composition be stated by percentage? and consequently the results would differ merely by some fractions of a grain, provided at least that the 100 grains were carefully chosen, and consequently the result would still refer *accurately* merely to the *individual* specimen. On these accounts, therefore, it is clear we can only judge from the *general* result of the analysis, and must not take into account *minute proportional* differences.

Again, there are many serious objections to the application of the ordinary methods employed in the analysis of organic bodies; for example, the usual plan adopted for examining vegetable substances, is to determine the relative proportion of the various proximate principles, which are more or less common to all, and which is effected by

dissolving them in succession in various menstrua. Such an analysis, however, would be utterly useless in the present case, for the following reasons. When we analyse a manure, it is of course for the purpose of ascertaining its fertilizing effects, which depend upon the four following circumstances. 1st, The quantity of organic matter which it contains. 2nd, The proportion of this which is already soluble. 3rd, The condition of the remaining portion, as regards its *tendency* to become soluble. 4th, The constitution of its saline matter.

Now, the only liquid solvent which exists in soils is water; it is clear, therefore, that ascertaining the proportion of any manure which is soluble in alcohol or ether, would be so much labour lost; neither could it be of any practical utility to determine the proportion of saccharine matter, gum, fecula, and the like, of which the vegetable portion is made up, as all these are decomposed, and become converted into entirely new compounds, before they are taken up by the roots of plants for the purpose of their nutrition. It was therefore necessary that some other method should be adopted; and after careful consideration, the following process appeared to hold out the greatest advantages.

The quantity employed was 100 grains, selected with care sufficient to ensure its containing all the *characteristic* ingredients of the species. It was, *first*, dried at a temperature of 212° Fahrenheit. This removed all the uncombined water, and along with it the volatile salts of ammonia, if such existed, which latter were detected by their proper tests. The proportion of these was of course indicated by the loss of weight sustained by the specimen under examination.

Second, The next step was to ascertain the proportion of soluble matter, which was done by washing the dried mass with pure water as long as the liquid was coloured, allowing the insoluble matters to subside after each washing, and decanting the clear fluid carefully from the deposit. The residuum was then again dried and weighed, and the loss of course indicated the quantity of the manure that was soluble in water. The constitution of the soluble matter was not accurately examined, as it could be of no importance, considering that we are totally ignorant of the nature of the food of plants, farther than that it requires to be in the state of solution.

The next operation consisted in an attempt to ascertain the *tendency* which the remaining organic matter possessed to become soluble; this was accomplished by means of caustic potassa. It has been long ago proved, that alkalies aid greatly the decomposition of organic matter; in fact, when assisted by heat, they accomplish it in a few hours; and, moreover, as was to be expected, this solvent attacks first those portions which are decomposed with the greatest facility. It follows, therefore, that by acting upon any insoluble organic matter with caustic potassa for a certain length of time, and then ascertaining the quantity which has been rendered soluble, we obtain a sort of index of the *tendency* to decomposition possessed by the substance employed.

Third, The residuum was therefore next acted upon for a given time, by a given quantity of a solution of caustic potassa at a boiling heat, and the soluble matter again removed as in the former operation, when upon re-weighing the dried residuum, we obtained the proportion of organic matter rendered soluble by the alkali, and hence have an index to its tendency to decompo-

sition. This step of the process possesses also another considerable advantage, dependent upon the chemical action exerted between the alkalies and azotized bodies; namely, that it gives us some idea of the proportion of animal matter present by the proportion of ammonia produced during this operation; the utility of which is obvious, when we remember that the advantage possessed by animal over vegetable manures, and the relative value of such as contain both, depend in a great measure upon the quantity of azote or nitrogen which they contain. When we have proceeded thus far in our analysis, we have only to determine the quantity of organic matter still remaining, and the proportion of earthy and saline constituents.

Fourth, The residuum was therefore, in the next place, charred, so as to render it easily pulverizable, and the powder was then mixed with red oxide of mercury, and the mixture heated to a bright red heat; in this way, all the organic matter and oxide of mercury were driven off, and nothing was left but the earthy and saline matter of the manure: this was then weighed, and the analysis thus completed, with the exception of the saline matter, the constitution of which was still to be determined. As, however, quantitative analysis was not attempted here beyond what could be judged by the eye, on account of the extremely minute proportion in which some of them existed, a separate-portion was used, which was merely burnt to ashes without any previous preparation; this precaution was also rendered requisite from the fact, that a small quantity of the saline matter is invariably lost in the other processes, and likewise because the presence of the oxide of mercury is liable to produce alteration in the arrangement of the various acids and bases. The process employed to determine the constitution of the saline matter need not be detailed here, as it differed in no respect from that in ordinary use among chemists. It may be well, however, to remark, in reference to the saline matter, that it is generally supposed that the analysis of *ashes* cannot possibly give us a correct idea of the true constitution, as this is so liable both to be altered by the heat, and still more by the presence of charcoal, &c.; indeed, I have heard it remarked by an eminent chemist, that the analysis of ashes to discover any thing besides the saline bases, is "perfectly absurd." Strange, however, as it may appear, no other process has ever yet been had recourse to, nor indeed do I consider it necessary, on account of the following four considerations. 1st, The extreme difficulty of all other methods. 2nd, The much *greater* liability which exists in them to the occurrence of error, from the fact that most of our tests are more or less disigned by the presence of organic matter. 3rd, That the only saline combinations which have ever yet been discovered in plants, have contained acids which are either of *organic* origin (and hence produced by the plant itself), or of such constant occurrence, that no fertile soil exists which cannot supply them. 4th, That, with the exception of carbonic acid, no other acid except the organic ones *do* suffer decomposition; for, strange as it may appear to chemists, there is no doubt of the fact that sulphates, for example, are constantly found in the ashes of plants, although it is considered as a general rule, that these cannot resist the joint action of heat and charcoal. This fact I am certainly unable to explain, but its truth I have proved beyond doubt. In the following ana-

lysis, therefore, I have confined myself to the old way, namely, analysing the ashes, with the only difference that I tested the presence of carbonic acid before I applied the heat to the dried mass. Proceeding upon this method, I obtained the following results from the three manures in question.

Dairy Manure.—The mass from which the specimen was selected was of a dark brown colour, moist, and sufficiently putrified for practical purposes. The specimen itself was selected with care, from the parts where putrefaction had advanced to its requisite height, and many of the dry unfermented straws were removed, so that the whole constituted a very good portion for analysis.

1. One hundred grains having been accurately weighed, were exposed to a temperature of 212° Fahrenheit, so long as they continued to lose weight. The watery vapour which passed off was proved by the smell, and the application of a rod dipped in muriatic acid, to be mingled with the carbonate and hydrosulphate of ammonia. The whole loss amounted to 45.7 grains.

2. The residuum was now steeped in cold water for twenty-four hours, and the coloured solution decanted carefully, so as not to lose any material quantity of insoluble matter, and this process was repeated as long as the water was at all coloured, after which the insoluble matter was again dried and weighed. It had now lost nine grains more, so that this manure contains 9 per cent. of soluble matter, which, of course, will be chiefly organic, although it will undoubtedly contain the soluble saline matter likewise.

3. The residue now presented exactly the appearance of decayed straw, a considerable proportion of which was reduced to the condition of very fine fibres, owing to the softer parts having been removed by putrefaction. It was now acted upon by two fluid ounces of liquor potassæ, and, after standing some time, was raised to a boiling heat, and kept in a state of brisk ebullition for fifteen minutes, after which it was allowed to cool. The solution was of an intense brown colour, but similar in other respects to the watery solution obtained in the last process. Upon diluting it with pure water, a flocculent precipitate appeared, which was allowed to subside before decanting off the clear brown solution. The residue was then repeatedly washed with cold water, to remove all soluble matter, as well as all traces of potassæ, after which it was again dried and accurately weighed; the loss in this part of the process, amounted to 12.6 grains. During the boiling of the residuum with the potass solution, large quantities of ammonia were given off, thus proving the manure to be rich in azote.

4. The insoluble matter was now incinerated in a platinum crucible, subsequent to which it was carefully pulverized, and mixed with about four times its weight of red oxide of mercury, and the mixture heated to redness in a crucible of porcelain. Nothing but earthy and saline matter now remained, the loss in this process being 21.8 grains, thus leaving 10.9 grains for the weight of the saline and earthy constituents. The constitution of this manure may therefore be stated thus:

Water and volatile matter.....	45.7 grains
Organic matter.....	43.4
Saline and earthy matter.....	10.9

100 grains.

5. Another portion of the same mass of manure

was taken, and burnt to ashes in a Hessian crucible, and the ashes being removed, were acted upon by distilled water, which, after filtration, was subjected to a careful *qualitative* analysis, the *relative proportion* of each ingredient being judged comparatively by the quantity of precipitate yielded to their several tests: in this manner, the solution was found to contain muriatic and sulphuric acids, and soda, potass, and lime. The insoluble part was now acted upon by boiling muriatic acid, and the solution thus obtained was found to contain lime, and oxide of iron, and alumina; it likewise gave probable indications of the presence of phosphoric acid, but owing to the presence of alumina, it is extremely difficult to detect this acid with positive certainty. The portion still left undissolved consisted of silica and alumina.

6. A small quantity of the manure, carefully dried, was tested with muriatic acid, and proved to contain abundance of carbonic acid. The minute constitution of this specimen of dairy manure may therefore be stated as follows:—

Water, with carbonate of ammonia and hydrosulphate of ammonia.	45.7	grains.
Soluble organic matter.....	.9	
Organic matter soluble in caustic potass.....	12.6	
Organic matter destructible by heat.....	218	
Silica.....	}	10.9
Alumina.....		
Peroxide of iron.....		
Carbonate of lime.....		
Muriate of soda.....		
Muriate of potass.....		
Muriate of ammonia.....		
Sulphate of potass.....	}	45.77
Phosphate of lime.....		
Sulphate of lime.....		
	100	grains.

Stable Manure.—The specimen used in this case was well rotted, but had been allowed to dry considerably, and evidently contained sand as an accidental ingredient; in other respects, however, it was remarkably well suited for analysis.

1. One hundred grains were accurately weighed and dried as in the former case, during which process they sustained a loss of 13.5 grains; the watery vapour containing both the carbonate and hydrosulphate of ammonia.

2. The dry material was now washed repeatedly in water, which removed 11.5 grains.

3. The residue now presented the appearance of soil, together with a few remnants of straw, owing of course, to the adventitious presence of sand, and also to the putrefaction having gone to a greater length. It was now acted upon by two fluid ounces of liquor potassæ, and boiled for fifteen minutes. On diluting the cooled solution, very little of the flocculent precipitate made its appearance, which quantity was however allowed to subside before decantation; after repeated washing, the residuum, when dried, was ascertained to have lost 15.9 grains. During the action of the liquor potassæ, a copious discharge of ammoniacal vapours took place.

* N.B. The saline and earthy substances are placed as near as possible in the order of their quantity, that in greatest quantity being placed at the top of the list.

4. The material was now charred, pulverized, and mingled with oxide of mercury as before, and the mixture heated to redness in the porcelain crucible, during which operation 13.33 grains were lost, thus leaving 45.77 grains of saline matter; much of this, however, was obviously the mixed sand, as another hundred grains, when burned with equal care, left only 28.25 grains of ashes. The constitution of this manure, therefore, is:—

Water and volatile matters....	13.50 grains.
Organic matter.....	40.73
Earthy and saline matter....	45.77

100 grains.

5. Another portion of the manure was carefully burned to ashes, and these were treated as before, and found to contain: In the watery solution—sulphuric and muriatic acids, and lime, soda, and potass; in the acid solution—alumina, lime, and peroxide of iron, with similar indications of phosphoric acid, and there was left a considerable residue of silica.

6. A portion of dry manure was proved to contain carbonic acid. The particular constitution, therefore, may be stated as follows:—

Water, with carbonate of ammonia and hydrosulphate of ammonia.....	13.5 grains.
Organic matter soluble in water.....	11.5
Organic matter soluble in caustic potassa.....	15.9
Organic matter destructible by heat..	13.33
Silica.....	} 45.77
Alumina.....	
Peroxide of iron.....	
Sulphate of potass	
Sulphate of ammonia	
Sulphate of lime	
Carbonate of lime	
Muriate of soda	} in small quantities
Phosphate of lime	
<hr/> 100 grains.	

The large quantity of silica, alumina, and peroxide of iron, of course, depended upon the presence of the sand, which was evidently ferruginous. We may, therefore, I think, safely infer, that stable manure does not differ materially from that derived from dairies, in the quantity of saline matter it contains. The other differences will be spoken of afterwards.

Street Manure.—The specimen used in this instance was taken from the street deposit at Newington, from a heap which was in the act of being carted away by a farmer, who informed me that it was fit for use. The hundred grains were equally selected from what appeared the richest part.

1. The hundred grains lost in drying 26.1 grains; by the usual test, a very small quantity of carbonate of ammonia was detected, but there was no evidence of the hydrosulphate being present.

2. The quantity of matter soluble in water amounted to 1.1 grains only; in fact, the very first portion of water was scarcely coloured.

3. When acted upon by the two fluid ounces of liquor potassæ, as in the former cases, a dark brown solution was obtained, which, however, on dilution with water, was almost entirely thrown down in the form of the flocculent precipitate

before mentioned, and the organic matter which remained dissolved amounted to one grain.

4. The residue was now evidently little else than ashes and cinders, which, by heating with oxide of mercury, lost 11.2 grains, thus leaving sixty grains of earthy residuum.

The composition of this manure, therefore, is :—

Water and volatile matters.....	26.4 grains.
Organic matter.....	13.6 ..
Earth and saline matter.....	60.0 ..
<hr/>	
100 grains.	

5. The saline matter obtained from a separate quantity yielded: In the watery solution—sulphuric acid and lime, with a trace of muriatic acid and soda: in the acid solution—protoxide of iron, peroxide of iron, alumina, and lime, together with a residuum of silica, the addition of the acid set free large quantities of carbonic acid, evidently mingled with sulphuretted hydrogen.

The accurate constitution of street manure may be thus stated :—

Water, with a trace of carbonate of ammonia	26.4 grains.
Organic matter soluble in water ..	1.4 ..
Organic matter soluble in caustic potassa	1. ..
Organic matter destroyed by heat (chiefly coal)	11.2 ..
Peroxide of iron	} 60.0 ..
Protoxide of iron	
Silica	
Carbonate of lime	
Alumina	}
Sulphate of lime	
Sulphuretted hydrogen*	
A trace of muriate of soda	}
	100 grains.

So much for the three manures. I shall now proceed to detail the analysis of the potato and turnip, which was performed in a similar manner, with the exception that the whole organic matter was determined by charring, as, of course, in order to compare a crop with a manure, it is unnecessary to know any thing more about the organic matter than merely its quantity.

Potato.—The one selected was of the growth of 1839, but had obtained its full size. I did not consider it necessary to ascertain to which of the numerous varieties of the potato the specimen belonged, as the statement about the manures refers to the potato as a species, not to any individual variety.

One hundred grains in drying lost 73.34 grains, which evidently consisted of water only. The residuum, when burned to ashes, lost 26.07 grains, thus leaving .59 of a grain for the quantity of saline matter.

The whole potato was now burned to ashes, and the saline matter tested as before, the result of which proved that,—in the watery solution, there

* I have placed the sulphuretted hydrogen by itself, as it is not very easy to say how it is combined: the most of it will undoubtedly be united to the protoxide of iron; circumstances, however, to be mentioned hereafter, would lead us to suspect that it is partly also combined with lime.

were present, carbonic, muriatic, and sulphuric acids, and potass; in the acid solution, lime, alumina, peroxide of iron, and indications of phosphoric acid. The addition of the acid set free carbonic acid, and there was likewise a slight residue of silica.

The minute constitution of the potato therefore is :—

Water	73.34 grains.
Organic matter	26.07 ..
Carbonate of potass.....	}
Muriate of potass.....	
Sulphate of potass.....	
Carbonate of lime.....	
Phosphate of lime.....	0.59 ..
Silica,	}
Alumina,	
Peroxide of iron,	
Sulphate of lime,	
	a trace
	<hr/>
	100 grains.

Turnip.—A good sized white turnip was selected. One hundred grains lost in drying 90.47 grains. The dried mass, by heating with oxide of mercury, lost 8.95 grains, thus leaving .58 of a grain for saline matter.

The whole turnip was now carefully burned, and the ashes examined as before, when, in the watery solution, carbonic, sulphuric, muriatic acid, and potass, lime and sulphuretted hydrogen, were found; and the acid solution contained alumina, lime, and peroxide of iron; there was a slight residuum of silica, and the addition of the acid proved the presence of carbonic acid.

The whole turnip, therefore, was constituted as follows :—

Water with some peculiar odorous matter	90.47 grains.
Organic matter	8.95 ..
Carbonate of potass.....	} 0.58 ..
Sulphate of potass.....	
Muriate of potass.....	
Hydrosulphate of lime.....	
Silica,	} a trace
Alumina,	
Carbonate of lime,	
Peroxide of iron,	
<hr/>	
100 grains.	

For the sake of comparison, I have subjoined the two following tables :—

1. Table showing the quantity of the various constituents in the five substances analyzed.

	Manures.			Crops.	
	Stable.	Dairy.	Street.	Potato	Turnip
Water, &c.....	13.5	45.7	26.4	73.34	90.47
Organic matter—					
Soluble in water	11.5	9.	1.4	26.07	8.95
Soluble in potass	15.9	12.6	1.0		
Destroyed by heat.....	13.33	21.8	11.2	0.59	0.58
Saline matter	45.77	10.9	60.0		
	100.00	100.00	100.00	100.00	100.00

II. Table showing the relative proportion in which the various saline ingredients exist, 1 denoting the least quantity, and so on.

	Manures.			Crops.	
	Stable.	Dairy.	Street.	Potato.	Turnip.
Muriate of potass	5	..	10	8
Muriate of soda	2	6	1
Muriate of ammonia	4
Sulphate of potass	6	3	..	9	9
Sulphate of lime	4	1	5	1	..
Sulphate of ammonia	5
Carbonate of potass	11	10
Carbonate of lime	3	7	11	8	2
Phosphate of lime	1	2	..	6	..
Hydrosulphate of lime	6
Silica	14	10	12	4	4
Alumina	13	9	10	3	3
Peroxide of iron	12	8	14	2	1
Protoxide of iron	13
Sulphuretted hydrogen	4

When the figures do not proceed in regular order, it shews that there is a considerable difference between the quantities; as, for example, in the turnip, silica is marked 4, hydrosulphate of lime 6, and muriate of potass 8, the difference in quantity being greater than between the other ingredients.

III. We must now commence the argumentative portion of this examination, and endeavour, as far as possible, to account for the inferiority of street manure for raising potatoes, by comparing the manures and crops together. In the first place, therefore, I shall sketch the character of the three manures, and compare them with each other.

Stable manure.—I place this at the head of the list, on account of its being the richest and strongest of the three.

This manure (arguing solely from the result of the *chemical analysis*) is evidently one of great value from the following circumstances. 1st, It contains a very considerable proportion of organic matter already in a soluble state. 2nd, It abounds with animal, as well as vegetable matter. 3rd, The insoluble parts have a considerable tendency to decomposition; for caustic potassa rendered more than half soluble, in fifteen minutes. 4th, It contains saline matter, of a constitution capable of supplying the wants of every kind of crop. *Mechanically*, this manure possesses the advantage of being (when properly prepared) easily incorporated with the soil; and from its organic matter being *equally* dispersed throughout, it may be termed *uniform*, that is to say, it will enrich equally the whole soil through which it is diffused, and not confine its effects to a few points only.

We may hence conclude *practically*, 1st, That this manure will be excellent for all crops; because it contains the essential ingredients of them all; 2nd, That it will not require very much putrefaction; because it contains a considerable quantity of soluble matter. 3rd, That it will *keep up* an abundant supply of soluble matter; because the undissolved portions have a considerable tendency to decomposition. 4th, That it will incorporate, and diffuse its effects equally through the soil; because it possesses a mechanical form which permits of its ready mixture with any pulverulent substance. 5th, It will be found more economical on strong, than light lands, on account

of its *tendency* to decomposition. 6th, It will be a hot manure, on account of the quantity of soluble matter. 7th and *lastly*, It will not be a very *lasting* manure, on account of its tendency to become soluble, which will of course render it more liable to be washed away, and also, will hasten those final changes, by which all the best parts of a manure are rendered soluble in air, and thus escape in the form of gas.

Dairy Manure.—This agrees in many respects, with that derived from stabler, for, like it, 1st, It contains a considerable, though less, proportion of soluble organic matter. 2nd, It is composed of both animal and vegetable substances. 3rd, The insoluble matter possesses a considerable tendency to putrefy, although not to the same extent as stable manure, for caustic potassa dissolved little more than one-third of the organic matter during fifteen minutes' ebullition. 4th, Its saline matter is equally applicable to all crops. 5th, It possesses precisely the same mechanical form, and consequently will diffuse its effects with equal facility.

We may therefore conclude, *practically*, 1st, that this manure will answer every purpose to which stable manure is applicable, except when a very *hot* manure is requisite. 2nd, That it will be better than stable manure for light lands, as it is less readily decomposed, and 3rd, That, from the same circumstance, it will be a more economical manure for the general use of the farm, as its effects will last longer, or in other words, because, from its more gradual solution, it will supply the plants for a greater length of time with nourishment prepared for their use, and less will be apt to be lost by undergoing total decomposition; for it must be always remembered in speaking of manures, that the changes which render them most serviceable to plants, take place during the *early* periods of putrefaction; so that they may be rendered comparatively useless by being allowed to pass beyond this point.

Street manure.—Now, let us see what we can make of street manure. Are the following words, "while it is nearly *equally* efficient in producing turnips, and some other descriptions of crop," which occur in the society's notification, to be understood *literally* or not? If so, we might almost be disposed to declare, that, of a truth, scientific examination is altogether useless; for if by the term *equally* efficient, it is meant that they are of the same value, ton for ton, what a fearful waste of manure must annually occur! For, from the analysis above recorded, street manure does not contain one-third of the organic matter possessed by the other two, and a considerable portion of this third consists of *coal*! Surely the meaning of the above quotation must be, that street manure applied in the ordinary manner, produces an effect nearly *equal* to an ordinary dressing of the other manures. In which case the fact is more explicable, as I have been informed that *double* the quantity of street manure is used, and that it is applied almost every year, which, of course, makes a most material difference, as then we shall, at all events, have about two-thirds of the quantity of organic matter contained by the others, especially when we take into consideration its more frequent application.

From its *chemical analysis*, we may conclude, 1. That it contains soluble organic matter in small quantity. 2. That this matter is a mixture of animal and vegetable substances. 3. That the soluble organic matter does not possess any very great tendency to decompose, for caustic potassa

dissolved but little of it. But, that a considerable quantity would in time become soluble, was proved by the fact, that the strong potassa solution was of a dark colour, and there was a copious deposition of flocculent matter upon dilution. And I may here remark, in reference to this flocculent precipitate, that it gives us an additional index to the decomposing tendency of the manure; for as strong caustic potassa acts much more powerfully than a weak solution, so, by the former, much organic matter is dissolved which would remain unaltered in soil for a much greater length of time than those portions which are dissolved by a weak solution. The precipitate, therefore, which appeared, of course consisted of these less destructible parts, and, consequently we may conclude from their presence, that the tendency to decomposition is not nearly so strong. In accordance with which it will be observed, that very little precipitation took place upon diluting the potass solution of stable manure, where, as before stated, the tendency to putrefaction was very strong. 4. Its saline matter contains one or two very dangerous ingredients, namely, iron and sulphur; both of these, indeed, occur in the other two, but in less quantity, and, moreover, the iron is in the much more harmless state of peroxide; here, however, the protoxide exists also, and, from the quantity of sulphur present, there can be little doubt that the two exist in a state of combination. This compound, so long as it remains unchanged, is not injurious to plants, but, unfortunately, such is by no means the case, for, when exposed to the joint action of air and moisture, which are exactly the circumstances in which it is placed in this manure, it is very apt to undergo an entire change, especially when combined with a similar compound of the peroxide of iron, whereby it becomes soluble, and in this state is an active poison to most plants. This change would undoubtedly take place very frequently, were it not for the presence of a considerable quantity of carbonate of lime, which acts as a preventive, by decomposing the injurious compound as soon as it is formed. Nevertheless, its presence renders the manure a dangerous one, especially in situations where the carbonate of lime is requisite for other purposes, as, for example, in sour peaty soils. The large quantity of lime, together with the presence of sulphur, may, however, be one of the chief reasons of its efficacy in raising turnips, as we shall endeavour to explain presently. In other respects, the saline matter varies but slightly except in quantity, from that of the other two. 5. Mechanically, street manure differs considerably from the other, and this point must be particularly adverted to. It may be observed, in the first place, that whereas the saline matter of the other two constitutes a part of the various organic substances composing them, and consequently they may be said to consist altogether of organized matter, in street manure by far the greater part of it is altogether extraneous: or in other words, while dairy and stable manure belong to the class of vegetable animal manures, this is included in the mixed, or those which are composed of organic and mineral substances. On this account, the organic matter is by no means equally spread throughout the mass, and consequently the manure may be considered *partial*, or one which, however well incorporated with the soil, would be very apt to fertilize certain spots, much more than others in the immediate neighbourhood. Moreover, the form of the mineral matter is likewise very bad, for, in addition to ashes, it contains a considerable quantity of

cinders, each of which will act as a mineral sponge, and absorb a certain quantity of soluble organic matter, which until the whole is soaked with water, so as to allow the soluble matters to percolate through it, is rendered comparatively useless, as the tender fibrils of the roots are readily turned from their course by resisting substances, and therefore are by no means likely to push through the pores of a cinder. From all these circumstances, therefore, it appears to me, that it will require far greater ingenuity to prove why it is a useful manure for turnips, than to explain why it fails in raising good crops of potatoes; the only real valuable quality which it possesses being, that it is much more highly azotised, in proportion to the whole organic matter which it possesses, than any other two; for it will be observed, that carbonate of ammonia was distinctly found in it, although it contained little more than two per cent. of organic matter, soluble either in water or potassa, which two menstrua are capable of dissolving nearly all the azotized compounds generally met with in manures. The cause of this large proportion of azote must depend upon the ordure which it contains as a constant ingredient.

To sum up in a few words, therefore, we would say—that *stable manure* is the most heating, but is not so durable—that *dairy manure* is cooler, and much more lasting—that *street manure* is very inferior to the other two in every respect, and, in fact, would be little better than soil, were it not for the highly azotised nature of its organic matter, and probably also for the presence of a considerable quantity of chalk.

We shall now give a short account of the crops themselves, and see what light they will throw upon this unquestionably most difficult and intricate subject.

The potato is a plant which possesses a branched stem and *spreading* root, which, when it first commences to grow, is in most respects similar to other roots, but after the plant has attained a considerable size, tubercular masses form in various parts of its fibres, which increase rapidly until the plant arrives at perfection. Now, since it is for these tuberculous bodies that the crop is cultivated, it must be observed that the most important part of the crop is *produced* at a late period of the growth of the plant. With regard to the chemical composition of the plant, a few words will suffice, as it throws very little light upon the subject, farther than showing how small a quantity of manure is *absolutely* required by any crop. Nearly three-fourths, for example, of this plant is composed of *water*. The saline matter likewise of the potato is of a constitution, the ingredients of which occur in every soil. With regard, however, to the *ultimate* constitution of its organic matter, I may observe that it contains a considerable quantity of azote, as has been proved by the accurate analysis of M. Boussingault, who has performed so many careful ultimate analyses of all species of crops, that I did not think it requisite to repeat them, especially as, in addition to their extreme difficulty, they require very expensive apparatus, none of which I at present possess. From the result of his examination, it appears that the potato contains $\frac{17}{100}$ per cent. of azote, and that its leaves also contain $\frac{100}{100}$ per cent. of the same substance.

We may hence argue that a manure, to suit well for the potato crop, should possess the following qualities:—1st, It must be spread equally through the soil, so that the spongioles at the termination

of all the *spreading fibres* of its roots may be supplied with nourishment. 2d, It must yield azote during the *whole* period of the growth of the plants; in fact, rather more is required during the *latter* periods than prior to the development of the tubers; for, from M. Boussingault's analysis, it appears that they contain $\frac{1}{100}$ per cent. more of this substance than the leaves. In an economical point of view, therefore, the best manure for potatoes would be one which contained plenty of azote, but still did not decompose very rapidly; dairy manure for example.

The turnip.—This plant, on the other hand, has a very close root, and is cultivated for the fleshy part of the root, which begins to increase very shortly after it has attained any considerable size. In regard to its chemistry, there is one important point to be borne in mind, namely, that its saline matter contains one salt of by no means constant occurrence,—I refer to the hydrosulphate of lime, or sulphuret of calcium, as it should more properly be called. Now, of late, considerable stress has been put upon the existence of these peculiar saline compounds which occur in some crops; and it has been asserted, with very great plausibility, that they are quite essential to the growth of the plant, and that their absence is fatal to the success of the crop. Consequently, if this statement is strictly true, the most important requisite for a manure for turnips is its containing a supply of the hydro-sulphate of lime; and likewise, from the closeness of the roots, a uniform manure is not *absolutely* necessary, as this plant will draw most of its nourishment from a comparatively small extent of soil. By ultimate analysis, M. Boussingault has shewn that the turnip contains considerably less azote than the potato, the proportion being only $\frac{1}{100}$ per cent.; so that by no means so large a quantity of this substance is required; and lastly, the crop contains a very small proportion of dry organic matter, namely, less the 9 per cent. in the specimen I examined.

When any quantity of street manure is ploughed into good soil, the following changes will take place. The ordure and carbonate of lime—which are evidently the most powerful ingredients of this manure—will re-act upon the less decomposable organic matter, both of the soil and the manure itself, and thus bring the whole into a state of fermentation, the extent and intensity of which will be regulated by the quantity of these active ingredients, especially the ordure. This action depends upon the fact, that when any organic substance in a state of fermentation is brought into contact or mingled with any organic matter capable of fermenting, but not at present in that condition, the whole mass, after a time, undergoes the same series of changes, which are always accompanied with the escape of various gases, and the formation of certain soluble compounds, which latter constitute the chief food of plants.

Moreover, it has been long ago proved, that substances rich in azote are always the most prone to decomposition, and likewise are capable of exciting fermentation to a far greater extent in others of a less putrescible nature. Again, it is well known to farmers that chalk, or carbonate of lime, possesses the power of increasing the putrescent tendency of many vegetable substances, so that when applied to soils it renders them *richer*. But what is curious enough, at the same time that it causes the production of soluble matter by promoting putrefaction, it renders less soluble those portions already in a state of solu-

tion, by entering into chemical combination with them. On these accounts, therefore, and especially from the ordure being a very highly azotised substance, street manure will be capable of exciting putrefaction to a greater extent, considering the small quantity of organic matter which it contains, than one would at first sight be led to suppose. It must, however, be remembered, that as the putrescent effect will only be produced in the immediate neighbourhood of the active ingredients themselves, and as, moreover, these are mixed with a large quantity of other comparatively inert matters, this action is very liable to be confined to certain spots. Owing, likewise, to the presence of cinders, a certain portion of the soluble organic matter will be absorbed by these, and thus, for a time at least, removed beyond the reach of plants. But, on the other hand, it will be observed that from the highly azotised nature of its organic contents, the fermentation will be *rapid at the first*, and consequently the manure will be hot in proportion to the quantity of real manure which it contains.

Of the other two manures I need say little more than has been already remarked; after they are ploughed in they will of course excite fermentation in the vegetable portions of the surrounding soil, and thus a steady supply of soluble manure will be kept up for a greater or less time, according to the quantity employed and the other circumstances already mentioned when comparing these manures together; and owing to their being wholly organic, the fermentation will be more equally diffused throughout the soil. How is it that street manure, which as we have seen does not contain one-fourth the quantity of organic matter, is, nevertheless, nearly *equally* useful for raising turnips as that derived from dairies and stables.

The following reasons will, I trust, explain this satisfactorily.

1. It will be observed that in manuring turnips it is not necessary to use any very great *quantity* of manure, but that used must possess certain qualities, the chief of which is this: it must contain a considerable quantity of soluble matter *produced* by fermentation; which fact is evidently proved by the following considerations. We all know the immense value of bone-dust as a manure for this plant, and it must likewise have been a matter of surprise to many how small a quantity will produce a large crop. The same remark refers equally well to rape-dust; and in regard to farm-yard dung, Professor Low distinctly says, in speaking of the turnip crop, that it must be "*well rotted*." Now, bone-dust, rape-dust, and *well-rotted* dung, agree remarkably in the following characters, viz., that they contain a large proportion of organic matter already in a soluble condition, and likewise that, while the two former *speedily* ferment after they are ploughed in, the latter is already in that condition when it is first applied. From this, therefore, it is evident that the great requisite for a good manure for turnips is this: that it must be soluble, and either capable of entering *rapidly* into fermentation, or already advanced to that condition. *That street manure possesses this requisite, we have already endeavoured to prove.*

2. A manure for turnip must contain the hydrosulphate of lime, or at least be capable of supplying the elements of that salt; for it is self-evident that, since this substance exists in the plant (considering that neither of its constituents are of *organic* origin), it must be supplied to it

either by the soil or the manure. And as this salt exists in the root, which is the first part of the plant that issues from the seed, it is equally evident that a supply of this salt or its element must be at hand when the seed is sown. Here we have another reason why dairy or stable manure must be *well rotted* before they are in a fit state for the turnip crop; for in the recent state, the sulphur which they contain is not in a condition capable of being absorbed by plants, but, as our analysis has proved, when *rotted* this element exists in a volatile form, as the hydrosulphate of ammonia, so that it can be absorbed either in the form of solution in water, or in air; and since, moreover, both these manures contain carbonate of lime, or, at all events, since most if not every *soil* contains this substance, we thus have a supply of the elements of the hydrosulphate of lime ready for the plant as soon as it begins to push forth its root. *Our analysis has proved that the elements of this substance are contained in abundance by street manure.*

3. As before mentioned, the turnip possesses a close root, and, therefore, is capable of being nourished by a manure which, like street manure, is liable to confine its effects to certain spots.

We then see that the street manure of Edinburgh is remarkably suitable, in several respects, for the culture of the turnip crop, and, consequently, it is not surprising that, although by no means what can be properly termed a *rich manure*, it should be capable of producing fair crops of this valuable article of food.

Let us now, in the last place, answer the following question: How is it that the street manure of Edinburgh is inferior by about *one-third* to that obtained from stables and cow-houses for the raising of potatoes?

The following considerations will, I think, fully answer this question:—

1. In the account of the culture of the potato, given in Professor Low's excellent work upon Practical Agriculture, we find the following expressions:—1. "Dung will in all cases act most quickly upon young plants when it is well prepared, but extreme preparation of the dung is *not required* in the case of the potato. It is enough that it should be in *such a state of fermentation as that it may be readily covered by the plough.*" Thus proving that this plant does not require an instant supply of a considerable part of soluble matter. And, moreover, it is clear, that as the useful part of this plant is produced during the *later* periods of the growth of the crop, the greatest supply of food will be necessary at that time. But we have already shewn, that street manure, from the nature of its constituents, ferments *very rapidly at first*, and, consequently, its *greatest effects* will be in the very *early* periods of the growth of the crop. 2. The next sentence in Mr. Low's work commences thus,—"*The potato requires a large supply of manure.*" But we have already shewn, that street manure does not contain *one-third* as much *real manure* as either that derived from dairies or stables. 3. And a little below the above quotation occurs the following sentence,—"*Lime does not appear to act in a beneficial manner, and is rarely applied directly to this crop.*" But our analysis has proved that *lime* exists in *considerable quantities* in the street manure of Edinburgh; and as it has been exposed to great heat—for it is evidently derived from the ashes—it will, of course, be in the same state as *mild lime* when it is applied, and will, most probably there-

fore, have the same effect, which, according to Mr. Low, is "*not beneficial.*"

2. The potato, as we before stated, possesses a spreading root, and, consequently, must require a *uniform manure*, in order that all its parts may be equally supplied with soluble organic matter. But we have before shewn that street manure is *partial*.

3. The potato requires the greatest quantity of azote at the *later periods* of its growth; because the tubers contain considerably more of that substance than the leaves. But street manure, from the nature of its organic constituents, will ferment rapidly, and allow most of its azote to escape during the *early* periods of the cultivation of the crop.

These, therefore, appear to be the reasons why the street manure of Edinburgh is not so applicable to the potato as to the turnip-crop; and lest any one should suppose that these differences may be too trifling to cause an inferiority amounting to *one-third* of the crop, I beg leave to quote the following passage, from the 41st Number of the Quarterly Journal of Agriculture, page 78, which, although not directly connected with the subject of this paper, will shew how apparently trifling a circumstance produced nearly an equally great difference in the potato crop. In mentioning some experiments by M. de Dombasle upon "*earthing up potatoes,*" the following one is quoted:—"Eight rows of potatoes were horse-hoed, some little time thereafter they were earthed up, and when five inches high they were again earthed up. Other eight rows, in the same place, and under exactly the same circumstances, were only *horse-hoed* at the same time with the others, but received *no earthing-up* or subsequent culture. The rows that were earthed-up, looked more vigorous and thriving; but on taking up the crop, they weighed only about 1222 lb., whereas the eight rows that were *not earthed-up*, produced 1408 lb." Now, here there is a difference of nearly 200 lb. in eight rows of potatoes, produced by the mere difference, that, in the one set, the plant was a few inches deeper in the soil than in the other!

Conclusion.—At page 348 of this essay, I stated that, before concluding, I should endeavour to point out a few particulars, which well merited the attention of those practically engaged in the culture of these crops. This I shall accomplish by shewing the different circumstances, the knowledge of which would be requisite before the above statement of the inferiority of street manure for raising potatoes, or its utility for the turnip crop, could be considered as *absolutely* proved.

It would be requisite, in the *first* place, that the soil experimented upon should not only be of the same *nature*, but it must be under precisely similar circumstances of exposure or shelter, of dryness or moisture, of inclination or levelness; and, in the case of its being sloped, this ought to be in the same direction.

Secondly, The experiments with the different manures would require to be made in one season, in order that the weather might affect all in an equal manner.

Thirdly, The seed must, of course, be from the same parcel.

Fourthly, The *depth* at which the seed is sown, would, from M. de Dombasle's experiments, appear to be of the greatest importance.

Fifthly, The manures must be equally prepared; and,

Lastly, The crops themselves would require to be examined chemically, as it is far from improbable, that some manures may *apparently* produce better crops than others, when, upon chemical examination, they would be found to contain an *equal* quantity of true nourishment,—the additional weight depending upon the presence of a larger proportion of water; for there is no doubt of the fact, that different soils, and very probably different manures likewise, have the effect of rendering the crops drier or more watery, as the case may be.

The necessity of all these precautions, might, very probably, deter many persons from attempting any experiments of the kind; but every difficulty would be overcome, were the experimenters to take time for collecting facts, and, during each year (without in the least interfering with their ordinary pursuits), merely make out a register of *all the circumstances* connected with their various crops. They would thus, in a comparatively short space of time, collect such a multitude of facts, that a careful comparison of these would, undoubtedly, lead to many most important results, both in reference to the science as well as to the practice of agriculture.

That these pages may have the effect of inducing some few practical men to pursue this inquiry, is the earnest wish of the author. And should any of the hints he has thrown out be the means of guiding them to a successful conclusion, he will consider himself amply repaid for the many hours which he has occupied in examining the subject.

THE EPIDEMIC.

SIR,—The prevailing epidemic among cattle, horses, pigs, &c., having spread its direful effects in the country, I venture, through the medium of your journal, to offer some remarks on the disease, merely for public good. The symptoms I have found to vary materially, but the successful treatment not so much so. In neat cattle some have been seized with stiffness of the limbs, resembling what in some places is called cripple felon; others swollen in the feet, but mostly caused by long driving, they have cast their hoofs, they pine in condition rapidly, some with swollen eyes, cheeks, and tongues; they suddenly become hidebound, soreness on the chine and on the length of the back; in one particular case, the ears and tail of a cow rotted off; but all cases as yet have, by continued care and repetition of the doses, recovered. The mode of treatment I have pursued is to give 10, 12, to 16 ounces of Epsom salts, 3 or 4 ounces of sulphur, 1 drachm of camphor, 1 drachm of tartarised antimony, and 1 ounce of finely ground black pepper, mixed in 2 quarts of new malt-beer. The dose must be varied and repeated in proportion to the state and size of the animal.

Horses have generally been found with stiffened limbs, which alternately swell, or all four; swollen eyes, with a watery discharge, sometimes the uvea considerably enlarged. The treatment—bleeding, purging with castor oil and Epsom salts, blistering when required.

Pigs, those giving milk, have been seen dragging their limbs after them, and both young and old pining away. Repeated doses of gum assefetida and common salt has succeeded; and I have reason to believe that milk from diseased cows will infect them.

These observations are communicated to the public with a desire to obviate the losses to which farmers and graziers have been subject.

Yours, &c.,
R. CROSS.

Nafferton, near Driffield, Yorkshire, Aug. 24, 1840.

THE WIRE-WORM.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—In your paper of this day's date, 17th August, is a letter from a "Cumberland Yeoman," on the subject of the wire-worm, wherein he very wisely shows, how to ascertain the real nature of any and every grub infesting the growing crops. Were agriculturists generally to search more into the causes of the loss of their standing corn, and endeavour to ascertain, by observation, or through the instrumentality of some person who may have made entomology his study, they would quickly distinguish the different destructive larvæ, nor mistake the grub of the "Harry-long-legs," (*Tipula olaracen*) for the real Simon Pure, or "wire-worm." The former is well described by your correspondent; "the latter is of a slender cylindrical form, of a fulvous colour, with six legs, but so short as to be hardly visible beyond the sides of the body." The true wire-worm, is the larvæ of the click-beetle, skip-jack, spring-beetle &c., for it has many provincial names, but the scientific term is "*Elatea segetis*."

This little creature is an indiscriminate feeder, turning his attention and his destructive mandibles, alike to the roots of wheat, rye, oats, barley and turnips, whole fields of which have been occasionally sacrificed to its depredations. The eggs of the insect are laid in the ground, hatched into the form of the wire-worms in which second stage of their existence, they remain five years. This lengthened duration of their eating state, easily accounts for the loss of the farmer being continued more than one year.

Sometimes they have been known to lay bare wide tracts of meadow land, by feeding upon the roots of the grass. Starvation suggests itself as the probable cure. Could not this be effected by allowing the land infested with them, to remain fallow for a season? Possibly a month, or two at the most, would suffice to check their insatiable appetites. Heavily rolling the land, by compelling them to leave their under-ground haunts for the surface, thus becoming a prey to birds, might possibly aid the cause of extirpation.

The farmers' clubs now establishing through the length and breadth of the agricultural districts, by setting local enquiries at work, will greatly assist the occupiers in removing all nuisances.

Pardon this my trespass upon your time, and believe me to be, Sir, your obedient servant, and constant reader,

P.
Stokefene, Norfolk, Aug. 17.

ON BOILED BARLEY.

MR. EDITOR,—Am I to understand that H. S. considers four bushels of boiled barley an equivalent to the four bushels beans and four bushels oats? Perhaps he will be so kind as to inform me if he steeps the barley *any time* before boiling, and how long he considers it necessary to be boiled.

The work of my horses is chiefly on the road, they are in good condition, but then I feed them with hay, grains, and one-and-a-half bushel of cracked barley each horse. If your correspondent will be so kind as to reply to my queries, I shall feel greatly obliged to him, and be induced to try the experiment.

I am, Mr. Editor,

Yours very much obliged,

15th Aug.

A SINGULAR CASE OF CALCULUS IN A HORSE.

BY MR. W. RICHARDSON, V. S., PETERBOROUGH.

(From the Veterinarian.)

A brown cart horse, thirteen years of age, the property of Edward Compton, Esq., was attacked on the evening of Friday, June 5th, 1840, with symptoms of colic, and some antispasmodic medicine was sent home by the servant for him.

I received a message on the following morning from Mr. C., informing me that the horse was still in pain, and requesting me to ride over and see him. On my arrival, I found him down, but not apparently suffering very acutely. His pulse was not more than 45, and full; his ears and extremities were warm, and his breathing was not materially affected. He had been seen to stale, but no dung had been ejected since prior to his attack on the previous evening. I immediately examined him per rectum, and succeeded in withdrawing several pieces of hardened feces, which were thickly coated with inspissated mucus. Some purgative medicine was administered, combined with ammon, subcarb, and zingib. A stimulating embrocation was applied to the abdomen. Enemata were ordered to be thrown up, and some linseed gruel to be offered him.

I saw him again in the evening. The medicine had not operated, though a rumbling noise was heard in his bowels. No feces could be felt in the rectum, the pulse was not altered, the ears and extremities were warm. Repeat the medicine, injection, and embrocation.

JUNE 7TH.—The medicine had not operated, although Mr. C. had given him a bottle of oil during the night. A slimy offensive mucus adhered to the tongue and fauces—there was constant turning up of the upper lip, and he was continually sitting upon his haunches. The ears and extremities were icy cold—immense distension of the abdomen—the pulse not perceptible—and every symptom of approaching death. I told Mr. Compton that I had not the slightest doubt that the animal was suffering from a calculus or calculi in the intestines; a view of the case which subsequently proved to be correct. He soon afterwards died; and on examination after death the following appearances presented themselves.

The intestines were immensely distended with air. The cæcum did not contain a single particle of food, either in a solid or liquid state. At the right curvature of the colon, not far from the ensiform cartilage, was a rupture, and upon the parietes of the abdomen was lying a calculus, presenting in shape the exact appearance of the intestine itself at the part where it was situated. The outer surface of it was beautifully smooth, and resembling marble. The peritoneal covering, both of the intestines and of the stomach, portrayed no symptoms of inflammation, and the inner surface was perfectly healthy.

The contents of the stomach, and throughout the whole course of the intestinal canal, until within a short distance of the place at which the colon terminates in the rectum, were perfectly fluid, shewing that the medicine which had been administered had performed its office; but here a stop was put to its farther progress, for another calculus was so firmly fixed in the intestine at this part, as to set at nought the power of medicine and the skill of man to remove it. It was firmly imbedded in a

quantity of silicious matter, some portions of which were adhering to its outer surface, and having the appearance of small crystals of sulphate of magnesia.

The feces beyond this were hard and dry; but within about twelve or fourteen inches of the termination of the rectum was a patch of inflammation in the villous coat of the intestine, occasioned, I have no doubt, by a lump of hardened feces which was deposited there. With the exception of this solitary stain, and where the calculi were deposited, the whole of the intestinal canal presented a healthy appearance.

The diaphragm was in a complete state of emphysema.

The liver was remarkably soft, and of a clayey hue. The kidneys had entirely lost their structure, particularly the one situated on the left side, which merely required the slightest pressure of the finger to break down its texture in any direction. They were both filled with a thick purulent matter, resembling coagulated urine.

The pleura and the lungs shewed evident symptoms of chronic disease, and the heart was the largest I ever saw, weighing nearly eleven pounds. The walls of the right ventricle were not much thicker than a stout sheet of paper, while those of the left were, I should say, nearly four inches in thickness.

This horse had been in the possession of Mr. Compton for eight years, and during the whole of that period he had never had a day's illness, nor had he been rested a single hour on supposition of such being the case.

The largest calculus, and found where the intestine was ruptured, weighs 3 lbs. 13 oz., the smaller one 1 lb. 8 oz.

ON THE EFFECT OF CRUSHING OATS.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—Being convinced that both reason and common sense were in favour of crushed oats being more nourishing for horses, as food, than grain in its natural state, passing, as it does often, through the bowels without mastication, I am surprised to find, after repeated trials, that it is less nourishing in the bruised state than when given whole, and my horses uniformly all off in strength and condition when bruised oats are used. Can it be that mine are bruised too much into meal? Any information on this point, or on the advantages of cutting hay, straw, turnips, &c., from any of your readers, would oblige, yours,
BRUISED OATS.

North Britain, 26th July.

SIR,—In answer to your correspondent who signs himself "Bruised Oats," I have to express my entire concurrence in the views entertained by him regarding the use of crushed oats. I cannot give him a satisfactory or scientific reason for the cause, but after several years practical experience, I have found out that oats crushed, and hay cut, are not by one half so nourishing as when given to horses in their natural state. Without entering into the cause of this effect, I would recommend all persons who have the management of horses to try both plans for a short time, and experience will very soon point out which is the best. I am Sir, your most obedient servant.

ANTI-BRUISED OATS.

Edinburgh, 25th August.

TREES AND TIMBER.

In our paper on trees, some weeks ago, we ventured to recommend the planting of Scotch fir, as a species of timber likely soon to come into extended use from a new demand for it in our large towns, for paving the streets. This new kind of pavement is already common in London. It is also begun to be used in Manchester; and we have just seen a gentleman who was invited a few days ago to inspect a vast establishment now erecting in Glasgow for sawing Scotch fir to pave the streets of that city. Our smaller towns may very soon follow the example.

Moreover, the marshy and soft parts of our public roads may yet be laid with wood; and in any long severe pulls we can scarcely expect less, in this age of improvement, than that at least one track of timber planks will be laid down for the wheels after the manner of a railway, as we have seen stones sometimes used: stones are hard and *dumling*; but wood is easy for the horses. Let our country proprietors, then, pay some attention to this matter, and weigh the probability of a large demand for Scotch fir.

As the timber is otherwise of steady value, they can hardly do wrong in planting a good deal more of it than for many years they have been doing.

After a breadth of fir of any kind has been cut over, it becomes a point of consideration what is to be done with the vacant ground. Many proceed immediately to plant it anew. They had better not.

Myriads of insects peculiar to wood have been bred and fed in the place, during the growth of the preceding crop of trees, and if young trees are planted immediately, they are sure to fall upon them, and in all probability mar their progress at once. We know, within six or eight miles of our own town, a breadth of wood which, two years ago, was planted on newly cleared ground, and instantly assailed and utterly destroyed by the vermin referred to. A space of at least a couple of years should be allowed to elapse before any ground, cleared of a crop of timber, be replanted. In this time the destructive insects have either perished on the spot, or are completely dispersed. Moreover, from the shaking of the trees, with the roots running through the earth, a great looseness and dryness of the soil takes place as a matter of course. Now, two years is by no means more than enough of time to allow this loose soil to settle down to the firmness of its original and proper state. The crops of long grass, which spring up in the meantime, besides fertilizing the place as they rot, are ruinous also to the special insects which haunt the spot, and thus make double preparation for a new planting. Now is the time also for the proprietor to see that new drains are put into the vacant ground, if any are required.

In replanting land which has been cleared of timber, it is a point of great importance not to put the same kind of trees upon the same ground; but to change the crop. Never plant larches where larches have already grown; but they may come very well after Scotch fir. In the same way oaks, Scotch spruce, and silver firs may succeed larches. Where a great breadth is to be laid down—whether new or replanted—we need scarcely point out to proprietors the necessity of having plenty of well-made roads, not only through such plantations, to get thinnings and future timber easily carried off, but also through the contiguous grounds, that tenants may not be afterwards annoyed by having their fields cut up, nor heart-burnings raised between them and their landlords or the wood-merchants.

One of the greatest errors in the management of young plantations of hard wood, is too much pruning.

We would boldly say at once, let there be no pruning whatever. Lateral branches are quite indispensable as feeders for the future growth of the tree. Whatever superfluity there is in this way, nature will throw it off in the shape of decayed branches, and relieve herself. The young stem will thus, moreover, be kept free from those unsightly sores which follow pruning, and which are constantly breaking out into as many feathery sprouts as more than exhaust all the quantity of sap and strength that the unlopped legitimate branch itself would have done. The great point is to relieve your young hard wood by early and careful thinning of the larches, and other soft trees put in for sheltering nurseries. By no means let them grow up to such an age near your young oaks, as that their resinous juices shall drop on these oaks, and cause sores, as they seldom fail to do.

Whether it is cheaper and better for a country laird to plant his land with the seedlings from the nursery, or proceed at once to dibble his acorns and thus rear his trees from their very first germ? The latter mode, including the expense of dibbling, costs only about £1. 5s. per acre; while the expense of the former mode cannot be less than £3. 10s. Be it remembered, however, that there is much time lost in the very slow growth of the acorn to the plant, which, on a fine soil, is a most important consideration. Upon the whole we would decidedly advise that, on all first-rate soils, planting should begin at once with the young oaks from the nursery. In rocky places, however, very bare of soil, such as many of the hills about Colvend and other districts in Galloway, which are most suitable for coppes, it is certainly the best plan for proprietors to dibble their own acorns, doing it carefully. For among such rocks there is not sufficient soil to give at once the right continuance of nutriment to plants drawn from the rich beds of the nursery, and they languish accordingly. When the seedlings have grown three years or so, and appear sickly from want of soil, let them be cut over. The plant thus cut stoles out afresh, and with renewed vigour, sending out its shoots on all sides. Why are not all the rocky hills and braes in Galloway turned to proper account by being clothed with oak coppice?

The greatest care must be taken in planting, to have no inferior plants. No considerations of comparative cheapness should make proprietors, in their contracts with nurserymen, run any risk of this kind; nurserymen may engage to keep up the plantation for three or four years; but if their plants are inferior, only think how little all this keeping-up, as it is called, can atone for the loss of time in the successive plantings of one set of defective trees after another in a great breadth of young wood in a good soil, where every year should be telling on its continuous and unbroken growth. We could point out various instances of the ruinous policy of this sort of work. Let it suffice, however, that we have given the warning.—*Dumfries Herald*.

In the leading article of the Mark Lane Express, published on the 23rd of September in the last year, we offered some remarks upon the proceedings at the Meeting of the "Northamptonshire Farming and Grazing Society," and especially in reference to a prize of 50*l*. offered by Earl Spencer for a short-horn bull, for the use of the farmers within twenty miles of Northampton, at the low charge of 5*s*. for each cow." In

the course of these remarks, we observed, "Landowners, and persons possessing the necessary capital, who may be desirous of improving the breed of cattle of any description, could not effect that object in so easy a manner as by bringing good male animals into the district for the use of the farmers." We have now very great gratification in being enabled to announce an instance in which this course has been adopted, and we trust the announcement of it will induce others to follow the example. Landlords, generally, little know, or perhaps do not consider, how much they have it in their power to promote the interests of their tenantry, to benefit themselves, and to further improvements in agriculture, at a very small cost.

Earl Brownlow, being anxious to improve the breed of short-horns in the neighbourhood of Grantham, recently sent his agent, Mr. Watts, into the north, to purchase, regardless of expense, the three best pure bred bulls he could procure, for the use of his lordship's tenantry and friends around his mansion at Belton Park, where his lordship has a herd, specimens of which have been successfully shewn at the meetings of the Smithfield Club. Mr. Watts executed his mission successfully, and the animals have arrived.

We have always contended, that the landlords should be the first to hold out the means of improvement, whether in reference to the introduction of animals of superior breed, newly-invented implements, or new experiments. We trust the example of the noble Earl Brownlow will be speedily followed by many other landed proprietors.

THE QUEEN'S CHEESE.—The manufacture of the Queen's cheese, which has excited so much interest, is now going on quite to the satisfaction of the parties interested. Since we last saw it, this ponderous production has been removed from the place where it was made, and it is now in the care of Mr. Dunkerton, a respectable farmer of West Pennard, who has assigned a neatly-furnished parlour for its reception. The cheese required no less than sixteen men to convey it in safety to its present apartments, where upwards of 1,100 persons of every grade have been to see it, and have recorded their names in a book kept for the purpose. The great mass of luxury is protected by a wire gauze case, in a mahogany frame, surmounted by a handsome crown. The dimensions of this Leviathan of the Stilton, Cheshire, and Somersetshire creation, are three feet six inches in diameter, being about the span of a moderate-sized well, and nine feet four inches in circumference; and when presented to her Majesty, which important ceremony it is not expected will take place for the next 12 months, it is fully anticipated that it will weigh half a ton. It is now as sound as when first removed from the vat, and has perfectly retained its octagonal shape. We think that the respected individual in whose care the cheese is placed must now be tired of his charge, considering his numerous visitors, and the time it must occupy to answer their inquiries; but we presume he is quite compensated for the trouble he has taken by the conviction that his labours will at no distant day be the means of making many of the industrious poor of his neighbourhood rejoice, when the contents of the box he has for the reception of the free contributions of those who shall have called to admire the cheese are distributed amongst them. Then we think our friends will have reason to congratulate themselves on the success of their exertions. A song has been composed on the subject, and set to music!—*Bath Paper.*

NEW VARIETY OF GRAIN.

In almost all the numerous discoveries and improvements that are daily made in the arts and sciences, more or less interest is felt by those individuals only who are engaged in the pursuit, or who expect to derive advantage from them. But though the feeling is partial with regard to objects involving particular interest, yet when any improvement is effected in agriculture, by increasing the means of production, or a discovery is made of any grain or vegetable likely to add to our stores, or augment our comforts, all classes then, from the throne to the cottage, participate in the benefits resulting from it, and ought to be grateful and assist in extending its advantages. Amongst the greatest improvement of modern times the subsoil plough may be considered to take the lead; and we would strongly recommend the landlords of this country to read the different publications on this valuable instrument, and apply it to those soils where its advantages have been made so apparent in similar ones in Scotland, England, and parts of Ireland. But our object at present (and we think it will gratify our readers) is to direct their attention to a new variety of grain, of which a trial has been made this season in England, but of which sufficient quantity has not yet been raised to enable the true test of its future usefulness (field culture) to be applied to it. Last year a mechanic in Bedale, Yorkshire, received a letter from a relative in Peru, South America. In it were a few grains of what he called Peruvian barley, which, he stated, produced two crops from sowing in that country, that is, when one crop was reaped, shoots were proceeding from the stems, which the same brought to maturity. From curiosity more than any other motive at that time, these grains were planted in a garden, and those that vegetated produced a number of stems each, which came to maturity. This year, not having any place where the grain could be safely sown and taken care of, he was kindly permitted to occupy a bed 21 yards long and seven feet wide, in the garden of a lady of fortune in Bedale. Some more of the grain was grown in a little garden of his own, and the produce of one indifferent head was cultivated in the garden of the Rev. John Monson.

The corn grew luxuriant, and produced from some of the grains upwards of thirty stems: from its great height and luxuriance it suffered from the severe weather in July, but it was cut the 10th of August. There were some green stems growing from the root at the time, but not sufficient to justify the expectation of a second crop in this climate. The grain when standing has the appearance of barley, but much whiter, with a long beard or awn. On being pulled and rubbed in the hand the awn comes off with the husk, and leaves the grain bare like wheat, to which it bears then a stronger resemblance than to barley, and by some is considered a species of wheat. To show the enterprising and speculating spirit of Englishmen, 100*l.* was offered for the small produce of the small spot of ground above mentioned, on which the crop, notwithstanding the disadvantage of the season, was very great, but could not be more than 6 stone. We understand this sum was refused, the owner expecting to get more by selling it in small quantities. A specimen of the grain in the ear and straw may be seen by any person taking an interest in agricultural matters, at Sir Robert Bateson's, to whom it was given by the Rev. John Monson, who has saved at least three hundred ears from the one which he planted. It is but a just tribute to the gentleman

above named to notice the constant exertions he is making to benefit that much deserving class, the agricultural labourers. He has greatly diminished the extent of the land he himself occupied, by giving it to a number of them in allotments of one-fourth of an acre each. The quantity of land so appropriated is very considerable, and the crops on many of the allotments afford strong evidences of the benefits of spade husbandry. The rest of his farm, in his own hand, is entirely under spade culture, and the crops are without any comparison not only the finest but the earliest in the neighbourhood. Great are the benefits he has conferred on that neighbourhood by his kindness in this instance. He might make other districts participate in it, if he would make public the results, not only in stating the quantum and value of labour necessary to produce each crop, but the periods of sowing and harvesting, as compared with the common method, together with the comparative return of grain and roots, as raised by the spade and plough on soils of a similar nature.—*Derry Standard*.

SHEEP BREEDING.

(FOR THE CARLISLE PATRIOT.)

It will scarcely be necessary to inform "Practical" that any person will run the risk of being considered more than commonly bold that undertakes to establish a new theory, when that has to be done in the teeth of old established and deep-rooted opinions and prejudices, strengthened, at least, if not in some degree originating in our abhorrence of the fundamental principles upon which that theory is built. "In and in" breeding in the human species is looked upon with abhorrence, and this will very naturally strengthen the objection to it in inferior animals. It is true there are two periods in the history of the world when "in and in" breeding must have been practised, but that was a matter of necessity, and as far as the human species were concerned, their repugnance to it might in their case, at those times alluded to, be counteracted and, in all its ill effects, be prevented by an all-wise and overruling power; but however bold such an attempt may be considered, I cannot be blind to my own temerity in venturing to oppose the opinions of so talented a writer as "Practical," who can wield the pen with so much dexterity.

With respect to "sturdy" or "giddy," I have seldom heard it attributed to "in and in" breeding, and I certainly do not think it originates in that cause, nor do I think there is the slightest analogy between sturdy in sheep and insanity in man. Although this disease produces such a serious effect upon the animal, yet we have no reason to think that its mind (if I may be allowed to make use of the term as applied to a sheep) is at all affected; nor does "Practical" shew very clearly that this disease is owing to a contracted or ill-shaped skull; "Although the veriest butcher's boy in cleaving down the head of a giddy sheep, comes to an incised watery tumour which may be handled and extracted without bursting;" we are not informed that it is invariably found in small contracted ill-shaped heads, or that it was never met with in a large capacious—or, in short, what "Practical" seems to look upon as the beau ideal of a sheep's head. Being strongly opposed to "in and in" breeding, I have avoided it as much as

possible, and I have no distinct recollection of having a sheep affected with "sturdy," nor one that died of rot. Whatever may be the proximate cause of sturdy, I am not going to contend that "in and in" breeding is the immediate cause of the rot, and I have already said that I do not consider it the cause of sturdy, though it may in some cases be the remote cause of both, by inducing a predisposition to disease from a delicate constitution, the consequence of "in and in" breeding. If the general opinion be correct, that from "in and in" breeding being frequently repeated, the flock becomes small in bone, diminutive in size, bare in the wool, and shews altogether strong symptoms of degeneracy, it is also very probable that a feeble constitution and a predisposition to disease will be their concomitants. Not having practised "in and in" breeding myself, I cannot, of course, speak from my own experience; but I must confess that nothing that I have met with in "Practical's" letters on the subject has been sufficient to remove from my mind the prejudice—if it must be called so—against "in and in" breeding. Mr. Marshall's account of Mr. Bakewell's Bull D will hardly be sufficient to convince any one of the general advantages to be derived from the system; though the account of its being "more active and higher mettled at the age of twelve or thirteen months than bulls generally are at three or four years old," must be admitted to be at least amusing. I think that before "Practical" can establish his theory upon any thing like a solid foundation he must support it by the test of an experience much more extensive than any he has as yet adduced in its support. When by a proper and judicious crossing you get a flock generally possessed of the points requisite and desirable, and continue to do so through a long succession of years, it is not unreasonable to assume that you have adopted and pursued something like a right course, and will be more confirmed in that opinion when you are surrounded by others who, by pursuing the same system, have arrived at the same results. When "Practical's" theory has been tested by the experience of years, and in a great number of cases; when there are such a number of instances where parties have bred from the same flock, without any regard to the degree of relationship between the male and female, that it may be said to be general, and have succeeded in acquiring the qualities most desirable in sheep, and continue to retain or rather improve those qualities through successive years, and in all cases, then he may hope to upset the prejudice of those opposed to "in and in" breeding.

"Practical's" letter, No. 7, induces me to ask a question that ought to be understood at starting, viz., what is "in and in" breeding? He says, "Now, if by the judicious admixture of different flocks, you mean different breeds, you must be wrong, for that evidently would obliterate that peculiar breed, the new Leicester's; and if you mean different flocks of the same breed; that I submit is 'in and in' breeding." It is very easy to find different flocks of the same breed, the Leicester for instance, between which there is no near relationship, and certainly not that propinquity that I conceive to be necessary to constitute "in and in" breeding. All these different flocks may have been derived from the same original stock, but they must be long, ere this, out of the pale of "in and in" relationship. If I am wrong in this—if the words I have quoted are meant to bear the interpretation that their plain meaning seems to

convey, then "Practical" himself, he being an Englishman, and his wife (I hope he is possessed of heaven's best gift, a wife) an Englishwoman, is proving the soundness of his theory in his own case, and even Miss Lucretia M'Tab, the most modest and decorous of her sex, would scarcely stand acquitted of setting an example to encourage "in and in" breeding by marrying her fourteenth cousin, the tobacconist in Glasgow.

In his first letter "Practical" says, "First, show me that over much couining does really lead to fatuity of mind which has not yet been done." It may be very difficult to prove to the satisfaction of "Practical" by any instance that could be given that fatuity of mind was the result of "over much couining," but instances are numerous in which it has been attributed to that cause. I know one where the parties were as nearly related as they well could be, not to be brother and sister; they had several children who were completely imbecile in mind; and most likely "Practical" himself, if so minded, could, within his own acquaintance, find numerous instances confirmatory of such general belief. I shall not pursue the subject farther, but will leave "Practical" to trace these consequences to what cause he pleases.

I am, with great deference,
Aug. 15. A CUMBERLAND SHEEP BREEDER.

OBSERVATIONS, WITH THE RESULT OF SOME EXPERIMENTS

RELATIVE TO SMUT BLADDERS, OR PEP-
PER BRAND IN WHEAT.

ADDRESSED BY HENRY CLUTTEN TO AGRICULTURISTS.

GENTLEMEN,—With the hope of engaging the genius of some more competent person to a thorough investigation of the matter, I beg leave to submit to your notice the following remarks and experiments upon the above subject.

In regard to the physiological character of the disease I have but little to say. To attempt the refutation of any of the theories laid down by men of science requires greater powers of research than perhaps I have at my command; I cannot but regret, nevertheless, that the information afforded in any of their works which I have seen, should be of such a meagre cast; for I am compelled to avail myself of their assistance, and have consequently in the prosecution of my enquiries adopted the views entertained by the celebrated vegetable physiologist, De Candolle.

De Candolle first tells us that brand, or burnt ear, (more commonly met with in barley) is a distinct disease from bladders, but that both originate and are propagated in the same manner; and he calls them both species of Parasitical Funguses or Mushrooms, so minute as to be seen only by the magnifying powers of the microscope, and they vegetate and draw their sustenance from the nutritious matter of the kernels of the plant on which they are found. Mildew or rust bears some analogy to smut in its parasitical character of subsisting on the juices of other plants. The Fungus seen to grow on some trees is likewise a kind of parasite, as is also the Mistletoe; and both afford instances of one plant growing out of and feeding upon the juice of others. De Candolle goes on to state that the black powder, both in brand and smut, contains extremely small seeds or germs, which in thrashing, &c., adheres to

the seed corn, and are deposited in the earth with it; from thence, in consequence of their inconceivable smallness, they are conveyed by means of the spongioles of the root of the wheat plant, along with the fluid food supplied by the soil, into the circulating sap of the plant. He further says, he has noticed such plants as have imbibed these diseased germs, exhibit a difference in colour from healthy ones, and that when their ears shoot forth these germs commence vegetating in the ears, producing smut or brand according to its kind. In burnt ear the black powder, as every farmer is aware, is void of smell, and is not enclosed in bladders, but vegetates exposed externally; I need not say such is not the case with smut, which stinks, and comes to maturity enclosed in imperfectly formed kernels or bladders. In both cases it is found that the disease consumes all the matter which would otherwise have gone towards the formation of the grains of corn. Such is in substance the theory of De Candolle. How does it accord with the farmers' experience? If we look to the varied opinions held by them concerning different supposed remedies, their corroborative evidence is certainly very inconclusive: but what I am about to show is how such inconsistencies may exist in their reports, and why, supposing De Candolle's explanation to be correct, some persons fail whilst others apparently succeed in preventing the disease, although both profess to employ the same means. First, I will refer to the process of wetting with salt water. There appear to be four circumstances which may hinder the uniform effect of this mode of dressing. The first relates to the quantity of salt employed in proportion to the water, and the second to the time allowed for it to dissolve; inattention to these two remarks would produce a liquid of different strength at different times, and probably different results would be the consequence. The third refers to the time permitted to intervene between the wetting and the admixture of the lime, for if sufficient time be not allowed for the salt preparation to act before the lime be applied, the lime will of course absorb the moisture, and stay all further effect. The fourth relates to its secondary effect with the lime, as I shall explain by and by.

My second observations are directed to the liming of wheat. It is well known that there is a sensible difference between quick-lime and chalk, but perhaps every farmer is not aware that exposing quick-lime to the action of the atmosphere reduces it to its original state, and actually reconverts it into chalk. Quick-lime is caustic or corrosive in a high degree, (and who knows it is not on this property that its utility depends?) Chalk is perfectly inert, and destitute of such qualities; I am sure everybody must have noticed this difference, yet who is it that ever thinks of seeing or enquiring whether the lime which he buys be fresh burnt? or whoever dreams of excluding it from the action of the air after he has bought it, until it is required for use? The second source of error in the employment of lime may arise from not sufficiently wetting the wheat; lime, it should be understood, exhibits none of its caustic qualities without the aid of moisture, consequently if you have no moisture you have no action with the lime, and the amount of effect will, to a certain extent, bear a proportion to the quantity of fluid used; and I wish it to be particularly noticed that this fact applies also to the secondary effect of salt water already alluded to, as well as to the remarks which I have to make in regard to the practice of dressing with urine, and other liquids employed with lime. I have one more observation to make respecting lime, which is, that it is partially soluble in water; chalk

or lime long exposed to the air, is not ; if therefore any good depends on this dissolved portion, here is another reason for employing lime fresh from the kiln. Bauer, who has examined this subject, says lime-water is a remedy for smut.

It does not occur to me that there are any very important circumstances which can materially affect the operation of urine, beyond that of relative quantity already referred to ; due regard should however be had to its age, as it undergoes decomposition by keeping and exposure, as may be known by the strong ammoniacal smell which putrifying urine acquires. Fresh and stale urine may therefore be productive of different results.

I now come to consider the using of arsenic as a dressing. The proportions employed vary from $\frac{1}{2}$ lb. to $\frac{3}{4}$ lb. per coomb, but more frequently a $\frac{1}{2}$ lb. only ; this by some is simply stirred in dry with the seed wheat, a mode of procedure which seems to me perfectly futile, since not only are the chances ten to one whether every kernel gets a particle of arsenic upon them, but it must be the merest accident if that particle falls upon the precise spot where we may suppose a smutty seed to adhere ; or even if it should do so, I question whether it would exert sufficient power in its dry state to destroy it—for arsenic, like many other substances, requires moisture to liberate its caustic, if not its virulent properties. Other persons will mix the arsenic in a watering-pot full of cold water, a plan which is decidedly preferable as every kernel thus stands a chance of getting wetted all over with the liquid so poisoned, but as it requires 100 pints of cold water to dissolve only about 5oz. of arsenic, it is questionable whether it is sufficiently strong. The same quantity of hot water will dissolve about 120oz., therefore should it be found desirable it may be made of any intermediate strength between these two extremes. Granting, however, that the cold water plan is sufficiently potent, time must be given for the arsenic to dissolve, for if it be poured from the pot as soon as the arsenic is stirred in, the wheat will absorb the moisture from it before it has become impregnated with the poison. The third way in which arsenic may fail, is the most important of all ; and variability of time between the beginning and ending of the process is the cause of this also. Sometimes the arsenical liquid spoken of in the last method is permitted to remain upon the wheat a considerable time before it is sowed ; on another occasion perhaps the liming operation is proceeded with immediately ; now it should be known that instantly the lime is applied all further action is at an end, lime being the very article employed as an antidote for arsenic ; the moment it comes in contact with a liquid containing that poisonous substance it converts it into an insoluble, inert, arsenate of lime ; indeed, if it exerted no chemical effect whatever, it must necessarily stay its action, by absorbing the moisture which is essential to its efficacy.*

I will now proceed to show that lime is equally important in the process with blue vitriol, or sulphate of copper, and for similar reasons. Lime has the property of decomposing blue vitriol, and of forming an insoluble and consequently ineffective cupreous sulphate of lime, leaving the liquid void of any impregnation whatever.†

What is called the swimming and skimming process is doubtless very useful for removing whole bladders, as well as much of the powder, but I think it ought not to be entirely relied on, as much of the latter would still adhere in defiance of dipping.

Taking the ground that some or all of these things have the power of effecting the desired purpose, you see, gentlemen, how easy a thing it is to mar their effects altogether, or at least to give rise to uncertainty of result, by some slight omission or alteration in the process ; time, relative quantity, quality, and chemical decomposition, may each exert their influence in rendering your operations nugatory ; and doubtless there are other sources of error which have not occurred to my notice. Some of these details may seem scarcely worthy notice, and insufficient to account for the variability attending similar processes, but be assured if there is any truth in De Candolle's theory, it is important to be particular in the most trivial circumstances, or all efforts are vain ; but if his views are not entirely satisfactory, if your experience throws a doubt on his assertions, permit me to say, it is you agriculturists who have the opportunity and the means of clearing up the hidden mystery, and of ascertaining what is the proper and sufficient remedy ; but it is my humble opinion that you have not hitherto gone the right way to work ; such experiments require much patience, much attention, strict observation, and above all invariableness ; a fixed and determinate method ; be the process whichever it may, the minutest circumstance overlooked or neglected may defeat the object in view. This is never sufficiently regarded by persons unaccustomed to experimentizing, and by those who do not study cause and effect. It may be no trial of its utility to dress a whole crop of wheat by any particular process, and because when harvested it yields no smut, to argue from thence that the operation prevented it ; because it is possible no smut was sown. Neither perhaps would it be right to infer that any particular dressing was a failure, because you have here and there a bladder, for not only might the process be improperly performed, but there might be whole bladders in the seed corn which protected the powder contained within them from the action of the dressing, by means of their skins. Such might go to the ground in their entire state, or get broken in the drill. We are not quite sure either, that bladders are not capable of laying dormant for a considerable time in the earth, as other seeds are known to do ; nor that wheat from a smutty plant does not occasionally produce smutty corn. Indeed, gentlemen, there are many things to be taken into account in the examination of this subject, and it strikes me you will never arrive at the truth but by a course of systematic experiments instituted for the express purpose ; if I may be allowed to dictate, I would suggest that a quantity of sound wheat should be slightly moistened and well rubbed over with the powder from bladders till every kernel is thoroughly imbued with it, and that a portion of it thus prepared should be planted by itself. The remainder of the wheat so covered with smut I would divide into several parcels, and dress each parcel with a different dressing, taking a particular written notice of the exact manner each was treated, and likewise using care to keep a distinct account of the situation each is planted in. You would thus ascertain whether smut causes smut, and whether any of the things employed prevented it, and which was the best. A quantity of kernels from a bladdered plant (not the bladders themselves) should be sown separately, to

* If a mixture of fresh lime with water be added to a solution of arsenic, and filtered, and the filtered liquid be subjected to the usual tests, the absence of arsenic will be proved.

† I think this would be proved by proceeding the same as with arsenic, and afterwards testing it with ammonia.

see if they ever or constantly produce smutty ears. Whole bladders should be buried in well observed spots, and the precise spot be searched for a twelve-month or more afterwards, that sound wheat may be deposited in the exact place where the bladders were known to have lain; with the view of seeing whether the germ of the disease is capable of laying dormant for long and definite lapses of time, and then again springing forth into life. I would likewise recommend in reference to the process with arsenic, that the arsenic be boiled, or at least dissolved in hot water, as a liquid may be thus formed of any required strength, and which provided it were allowed to remain upon the wheat the same space of time would always act with uniformity, liquids being more readily diffused through a mass of corn than solids. Experiments would of course be required to determine what strength could be used without detriment to the future plant, whilst at the same time it insured the destruction of the vegetative principle of the bladder. From some trials which I have made, corn is capable of withstanding much stronger applications than is commonly supposed, but not having turned my attention to the subject till within these last few days, I had not time to make any decisive experiments; nevertheless, so far as they have gone, they exhibit some facts which may be worth notice. In all the trials, the seeds which I used, both of mustard and wheat, were put into the preparation during the processes, and remained therein for *twenty-four hours* afterwards; in the *first ten* experiments they were taken out of the ground, after remaining in it *four days*, and those which follow after, *three days*.

The 1st trial was with mustard seeds, in a boiled solution of arsenic, about forty times the strength of the arsenic liquid made with cold water.—The seeds had begun to decay.

2nd. Was the same mixture diluted to half the strength.—In this case the mustard seeds had begun to germinate.

3rd. With sound wheat in the first-mentioned liquid of the fortieth power.—They were swollen and appeared healthy.

4th. Wheat in half the strength.—Began to shoot.

5th. Mustard seeds in water impregnated with blue vitriol whilst cold, to saturation.—Found decayed.

6th. Wheat treated the same.—Healthy and commencing germination.

7th. Wheat in the same, diluted to half the strength.—In the same state of vegetation.

8th. Mustard seeds in quick lime, using such a quantity of water as left the lime still in a dry state.—They shewed some appearance of shooting.

9th. Mustard seeds in fresh urine and lime, in a liquid state.—Found decayed.

10th. Wheat in a saturated solution of salt (made with cold water).—Was found in a state approaching decay.

It will be seen, therefore, that the 1st, 5th, and 9th processes destroyed the vital principle of the mustard seeds, but not of the wheat. This shews that the vitality of exceedingly small seeds, may be obliterated without perishing those of larger size. The mustard seed died in the first experiment and lived in the second, although still twenty times the strength commonly used; the second, therefore, offers a proof of the strong mixture which is required to extinguish life, even in so small a seed as that of mustard; whilst the first shews us that the same preparation, when stronger, is capable of doing so.

Wheat, as we have seen, survived the strong arsenic and vitriol liquids, but perished in the salt. This I did not expect; if it should turn out an invariable consequence, it teaches us to be careful in the use of salt. The destruction of the mustard seeds occasioned by the lime and urine, at least set forth its powerful effects. It was not tried with wheat. The mustard seeds having survived a similar process in which water was substituted for urine, we might, at first sight, suppose the deadly effect was attributable entirely to the urine; but as in the water process the lime was still in a dry state, I have no doubt but the different result is referable to that cause. I had a mind to try the effect of hot water upon the vitality of seeds; thinking, perhaps, that might be found effectual for the purpose of destroying the disease. Boiling hot water was poured upon wheat in separate pots, and permitted to remain upon it, in the 1st case, half a minute; in the 2nd, one minute; in the 3rd, one and a half minute; in the 4th, two minutes; instead of extinguishing the vegetative principle, I found, after being planted only three days, that it had wonderfully accelerated the germination. The 1st had shot half an inch, the two next more, and the 4th full an inch; whilst mustard seeds treated the same, in no case shewed any sign of life; now as it destroyed the smaller seed, it is fair to conclude that water, perhaps not quite so hot, would be effective for smut. It is doubtful whether plants thus unnaturally forced, would continue healthy; if they would, such an operation might in some cases be useful. I have just been assured by a gentleman, that old wheat will not grow smut, even if not dressed; if this be true it may perhaps be accounted for from the dryness of old wheat not allowing the cause of the disease to adhere, or the seeds giving rise to the disease, or belong to a class which will not vegetate if kept beyond a year; at all events, if the fact can be substantiated, the cure for bladders is obvious, —never to plant new seed.

Gentlemen, I attach very little importance to my experiments with the seeds, as the time was too limited; but if in the course of my remarks, I have hinted anything which may lead to the successful treatment of wheat, for the certain destruction of bladders, I shall be more than rewarded for the little trouble it has cost me. I am, gentlemen, your obedient servant,

HENRY CLUTTEN.

Framlingham, Sept. 12, 1840.

ON THE HOOSE IN CALVES.

TO THE EDITOR OF THE FARMER'S MAGAZINE.

SIR,—Having been for some years a subscriber to your valuable Magazine, I shall feel much obliged by any of your professional correspondents having the kindness to inform me, through the medium of your publication, what is the best remedy for a disease called the hoose, which is just now very prevalent among calves in this neighbourhood.

In Vol. I., p. 30, of your new series, Mr. Mayer, of Newcastle, recommends lime water, alternated with a solution of salt water, but he does not state how often or in what quantities they are to be administered.—I remain, sir, your most obedient servant,

D. J. L.

August 26.

NITRATE OF SODA.

SIR,—I have tried a small quantity of nitrate of soda on a piece of pasture land, the good effect on which induces me to think of using a quantity; but several of your correspondents state, that *it is very exhausting to the soil*. I do not understand what they mean by this assertion: do they mean that land manured this year with nitre, although it may cause an increased crop this year, next year it will be worse than it was before any nitre was applied? if this be the fact, then I should say the soil is exhausted by its application, but if the crop be increased this year, and the ground no worse next year than it was before the nitre was applied, it cannot be said that the soil is exhausted by it. Land may be exhausted by repeated cropping and not manuring, but in the case of nitre if it causes such a vigorous growth for one crop it must be a good manure, and the same land the following year will be in better condition than it was before the nitre was applied. If this should prove not to be the case, I should conclude that nitre is injurious: the subsequent weakness of the herbage would seem to prove that though it assisted the crop on its first application, its effect on the soil, perhaps from some chemical combination, injures the fruitful powers of the soil which forms the food of plants.

Nitrate of soda dissolves in a day or two after being applied, consequently it enters into the composition of the plant immediately. I can easily imagine the crop taking up the strength of the nitre in one season, and that no particular benefit would be observable another season. Bones and dung are much longer in decomposing, and entering into the composition of plants, consequently their effects will be seen two or more years after.

I should like to know if nitrate of soda has any injurious effect on the soil, by destroying any of its vegetative powers by repeated application; if it does not destroy or in any way injure the powers of the soil, then, though no benefit may be seen a second year, yet a second application would produce as good a crop as the first.

Would it answer to sow nitrate of soda on the same land three or four years together?

What are its constituent parts, has it any thing of an oily nature in it, such as forms so important a part in natural dung?

It is a salt, but if the salt be the only portion which serves as the food of plants, then it would appear that repeated applications to the same soil would be injurious, the land would become too much impregnated with it, overpower or destroy the other properties of the land, and thereby exhaust it and render the same unfruitful.

I shall feel obliged by an early reply from some of your intelligent correspondents.

Yours respectfully,

Cheshire, Aug. 26th.

O. D.

When our attention was first directed to "the Benevolent Society for the relief of the widows and orphans of farmers," about to be formed by "the Midford and Launditch Association," in Norfolk, we were induced to make some remarks upon it, not altogether favourable, from the understanding that it was intended as a means of investment by the *parties interested*, with a view to future benefit to their families. Acting upon this

belief, we did not hesitate to recommend the "Farmer's Fire and Life Insurance Institution," as affording greater and more solid advantages than the proposed Society; we have, however, since been given to understand, by a gentleman who takes great interest in the society, that its objects are purely *benevolent*, and intended to afford *charitable relief*. As a charitable institution, therefore, as a means of affording comfort to the families of those farmers whose circumstances have been such as to leave their families in need of assistance, we heartily wish it success. We would, however, observe that the promoters of this society, whilst from feelings of the best kind, they seek to provide relief for those who, from inevitable circumstances are plunged into distress, would do well to inculcate the propriety of greater exertion on the part of the smaller farmers generally, to provide for the future. In "The Farmers' Fire and Life Insurance Institution," a man twenty-six years of age may, by the payment of £1. per annum, insure £50. to his family at his death, however soon it may happen. For two shillings a week, commencing at the age of twenty, he may secure an annuity of £20. per annum, to commence as soon as he shall reach fifty years of age, to continue for the remainder of his life; and in the event of his dying before he attains that age, or in case of inability to continue his payments, he may receive *the whole of the money back*.

ON FEEDING SHEEP WITH CORN.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—Having understood that young wethers when feeding on turnips will improve much faster by having some corn, or cake given at the same time, I hope some of your intelligent correspondents will be kind enough to inform me through the medium of your useful paper, whether the corn should be given whole or crushed; and what description of corn suits them best; also, if beans have been found to answer as well in the fattening of sheep as they have with bullocks: not being in a neighbourhood convenient for procuring oilcake, whether linseed is ever used for this purpose; and if so, should it be given in its crude state, &c.?

By inserting this you will greatly oblige,

A Novice.

FEEDING SHEEP.

TO THE EDITORS OF THE LEEDS MERCURY.

GENTLEMEN,—I find in Earl Spencer's address made before a meeting of the Agricultural Society, at Leeds, the following statement:—"That sheep feed much faster in sheds on account of the *rest* they obtain by having turnips carted to them." I believe sheds to be an excellent improvement, as it will protect them from the inclemency of the weather, and it is on that account it will cause them to feed faster, and not as stated by Earl Spencer as above, as cold wet weather is injurious to sheep or any other cattle.

Should this meet with your approbation, you will greatly oblige me by inserting it in your valuable paper for the benefit of the Agricultural Society. I should have noticed it sooner but in consequence of other engagements, was prevented.

I am, your's truly,

AN AGRICULTURIST.

Craven, Aug. 25th, 1840.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

At a monthly Council held on Wednesday, Sept. 2, present, David Barclay, Esq., in the chair; Thomas Raymond Barker, Esq.; French Burke, Esq.; Edward Greadhead, Esq.; Rev. W. L. Rham; William Shaw, Esq.; William Youatt, Esq.; the report of the Finance Committee was received and adopted.

Mr. Legard presented, on the part of himself and the other judges, a report on implements exhibited at the Cambridge Meeting.

Lord Worsley and Mr. Horwood each transmitted information on the progress and treatment of the epidemic among cattle; the former communication (from Lincolnshire) stating that by administering Epsom salts with nitre, and avoiding bleeding, none of the numerous cases had terminated fatally; the latter (from Northamptonshire) pointing out the predilection evinced by the cattle on recovery for the young shoots of the elder tree, and thence inferring the probability of this plant being a natural restorative for the cattle.

Mr. Baker Gabb addressed a letter from South Wales on the advantages to be derived from encouraging the breed of cattle possessing dairy as well as fattening qualities; Mr. Baines a communication from Lancashire on the importance of chemical enquiries into the nature and properties of milk; and Mr. Chawner, Secretary of the Lichfield Agricultural Society, suggesting the practical advantages to be derived from having crops in the neighbourhood of Liverpool, at the time of meeting next year, exhibiting the comparative merits of the Drills and Dibbling Machines employed in sowing for them.

Col. Le Conteur addressed a letter to the Council on the subject of the great meeting of the Highland Society to be held at Aberdeen on the 8th of October, and to continue three days.

Mr. Rham exhibited some beautiful specimens of wheat, and Mr. Norris, of Rodwell House, Baldock, transmitted specimens for the museum. Mr. Youatt presented a copy of Mr. Spooner's new work on the foot and leg of the horse; Mr. Shaw the new number of the "Farmers' Magazine;" the Highland Society the last part of the "Quarterly Journal of Agriculture;" the Labourers' Friend Society, the last number of their proceedings; the Statistical Society, their Transactions for July; the editor of the American "Cultivator," several numbers of that Agricultural Paper; and the Royal Society of Agriculture of Lyons, a set of their "Annales des Sciences Physiques et Naturelles."

Mr. Wetherell, of Durham, communicated his suggestions respecting the mode of conducting the sale of stock at the Liverpool Meeting. The following gentlemen were elected members of the Society.

Henry Spirling, Norbury Park, Leatherhead
Isaiah Deck, Cambridge
Mark Fothergill, 40, Upper Thames Street
T. Waring, Cherfield, Kent
John Abbey, Market Harborough
Edward Abbey, Creaton, Northamptonshire
Alexander Bell, Corn Exchange
G. Wood, Denver, Norfolk
J. Brown, Lea Castle, Worcestershire
T. Rodwell, Chaseley, Norfolk

The Council then adjourned to the 7th of October.

ON THE MANAGEMENT OF CLAY LANDS.

SIR,—The essays of your correspondent "J. D." are truly excellent and practical; that on rotations, which appeared in yours of the 31st ult., is admirable, and is a complete refutation of the fashionable, but absurd doctrine of dispensing with bare fallows on stiff clay soils. To any one who has been in the habit of cultivating clay soils, it must be evident that the crop of Wheat after a bare fallow is *always* more profitable than a Turnip crop (which is always inferior on such soils), and the succeeding Barley or Oat crop; the whole expense of growing the Turnip crop is saved by substituting bare fallow; the soil is saved by not carting on it in wet weather in getting off the Turnips; the immense labour of men and horses in spring in obtaining a mould for Spring Corn and grass seeds is avoided; and, after all, more value is got from the soil; who then will hesitate between the two systems? The great desideratum is the means of converting the straw into manure on this stubborn clay, without the aid of turnips; Oilcake has been used in some instances, but it is too expensive, and is not, besides, a substitute for the succulent, juicy, manure-making Turnip. Cannot your talented correspondent "J. D." help the poor clay land farmer to a remedy? I must also appeal to him as to the effect of ploughing in Beans, Tares, &c. &c. in fallows on strong soils: the clay farmer cannot have recourse to bones; rape dust answers well, but it is exceedingly expensive, dressing an acre with it would nearly amount to the value of the succeeding Wheat crop on inferior soil. If ploughing in green crops were found to answer as a manuring, it would be an immense gain to that unfortunate man, the occupier of a poor clay-land farm, as there would be but little labour, and the whole cost would be the price of the seed. I am aware that some will say "Tile-drain your land, and then grow turnips;" but this, Mr. Editor, you will allow is not always practicable, tenants of such soils are not overburdened with cash, and sometimes landlords are neither able nor willing to lay out 10*l.* per acre in draining their farms; I am certain your correspondent "J. D." is well aware of this fact, and that that is not the way he will answer the appeal of the poor clay farmer. I hope he will be induced to give us some information on the subject, particularly on the effect of ploughing in green crops on such soils, and he will thereby lay under great obligations, Your constant reader and subscriber,

A POOR CLAY-LAND FARMER.

North Britain, Sept. 5.

RATING OF TITHES TO THE RELIEF OF THE POOR.

THE QUEEN V. CAPEL.

The following circular, on the subject of rating of tithes to the relief of the poor, has recently been forwarded to the churchwardens and overseers of the various parishes throughout the kingdom, by order of the Poor Law Commissioners:—

"Poor-law Commission Office, Somerset House.

"RATING OF TITHES TO THE RELIEF OF THE POOR.

"Gentlemen,—The judgment of the Court of Queen's Bench has been delivered in the case of the 'Queen v. the Hon. and Rev. William Capel, Clerk.' The Court has decided that the title-owner is to be rated for his tithes, upon the same estimate of their net annual value as is provided for all other rateable hereditaments, by the first section of the Parochial Assessment Act (6 and 7 William IV. cap. 26), and that the title owner is not entitled under the proviso in that section, to any deduction or allowance corresponding with the profits of occupiers of lands, houses, &c.

"While the question as to the extent of the tithe-

owners' responsibility was in dispute, and with a view to prevent unnecessary litigation in the multitude of appeals which were then to be apprehended, the Poor Law Commissioners recommended, by a minute of the 8th of September, 1838, that a single case should be selected in some one parish for argument, and that in all other parishes provisional arrangements should be adopted between the overseers and the tithe-owners, which would allow of an eventual settlement of the payments to be made by the tithe-owners in conformity with the principle of any decision which might be obtained upon the selected case.

"The case of 'The Queen v. Capel' was eventually selected to try the question in dispute, and in accordance with the recommendation contained in the minute of the Poor Law Commissioners, the rates were in many parishes laid on the net annual value of tithes, and a portion only of such rates was collected, an arrear being allowed to remain proportionate to the deduction which the tithe-owners claimed.

"But rates on the whole net annual value being now, by the decision in the case of 'The Queen v. Capel,' determined to be correct, it has become the duty of overseers to collect from the tithe-owners any arrears which may have been allowed to accrue; and in future rates to assess the tithe-owners on the whole net annual value, and to collect the whole rate so assessed.

"By order of the Board,

"EDWIN CHADWICK, Secretary.

"To the Churchwardens and Overseers of the poor."

HOOSE IN CATTLE;

THE SPONTANEOUS CURE OF.

By R. B. Gellé, of Toulouse.

(From the Veterinarian.)

Our readers, we hope, will find both pleasure and profit from the perusal of this short extract. It is taken from portions of the lectures of the Professor, which we were compelled to omit in some previous numbers.

"The treatment of hoose in cattle is effected, first, by the escape of the disengaged gases, either by the mouth or anus; secondly, by the neutralization of these gases by certain medicaments; and thirdly, by the puncture or incision of the paunch, by means of which the gas and aliments are evacuated.

"Let us examine these different means, and the different indications which the varieties of meteorization present. When the extrication of gas is inconsiderable, the walking of the animal about will often effect a cure; but when the tympanitis is serious, other measures must be used. Liquid ammonia, or ether, may cause a sudden diminution in the bulk of the gas, or, in various cases, even of considerable intensity, nature has been found to effect a cure without the aid of art.

"Observation having proved that, in serious cases of hoose, the gas cannot naturally escape from the paunch in a sufficient quantity to effect a cure, it has been proposed to assist its escape by means of a flexible tube introduced into the œsophagus; but this proceeding is dangerous, especially in unskilful hands. Many medicaments possess the property of neutralizing the gas extricated from the aliments contained in the paunch. Chabert, considering that these elastic fluids were in a great measure composed of carbonic acid gas, recommended the use of certain alkalies, particularly lime-water, the potash of commerce, and more particularly liquid ammonia.

The success which attended this mode of practice gave it considerable reputation: it is at the present day the remedy most usually employed, in doses of an ounce and a half for the larger ruminants, and of two drachms for sheep, mixed in a pint of water for the first of these animals, and a glass for the second. Experience has proved to me its efficacy whenever the meteorization has been recent, and produced by green food, because in this case there has been no inflammation of the digestive organs. The effects of the medicine should be assisted by leading the animal about, and by clysters of warm water holding in solution some kitchen salt or common soap. These will generally produce the evacuation of the excrement accumulated in the large intestines.

"But, whenever the state of the pulse, the redness of the tongue, and the heat of the mouth, have caused me to suspect the commencement of inflammation, I have always had recourse to sulphuric ether, because it very promptly condenses gases, and does not cause any dangerous irritation. The spirituous infusion of balm has a stimulating and diffusible property which produces a dilatation of the membranes of the paunch without too much exciting the nervous system; and it is second in action only to the ether. 'This is one of those medicines which the veterinary surgeon should never be without,' says M. Prevost: 'I have the greatest confidence in ether. In effect, it often acts with an astonishing promptitude.' Whatever may have been the circumstances which have given M. Prevost so favourable an opinion of ether, I can only say that I was in the habit of using it a dozen years before the publication of the memoirs of that gentleman. I have been as successful with it in the flatulent colic of the horse as in the hoove of cattle. One circumstance, however, must be expected with regard to the cow—the milk will be spoiled, for it will acquire an almost insupportable smell of ether. This generally disappears on the third day, or on the fourth at the latest.

"M. Chalot has also a favourite remedy. Most of the chlorurets have considerable good effect in neutralizing the gases disengaged in the rumen; but that which, in his opinion, has most effect is the chloruret of the oxide of sodium.

"Whenever the meteorization is extreme, and the inflation of the rumen is so great as to interfere materially with the action of the diaphragm, and threaten a rupture of it, a puncture should be effected by means of the trocar. This opening should be made at the superior part of the left flank, corresponding with the superior face of the rumen, at an equal distance from the last rib, the external angle of the paunch, and the transverse lumbar apophyses. Although the operation should be a last resource, according to Fromage de Feugré, it is nevertheless essential that it should take place before all hope has vanished, as it is probable that the discredit which has followed its delay is more to be attributed to the previous hesitation and doubt of the persons employed than to the temerity of the surgeon. It is for the veterinarian to decide, cautiously yet firmly, on the proper time.*

* It is difficult to imagine what can be the cause of the hesitation and fear of the French veterinary surgeons with regard to the application of the trocar. We are in the habit of using it, and with much success, and never with bad effect, in an early stage of the complaint. We may be enabled to prevent a

"I would now make a few observations on nephritic indigestion, arising from over-feeding, a malady more frequently occurring among stalled beasts, or those who have been kept upon dry food. It is characterized by a less sudden distension of the rumen, with hardness and fulness of that stomach—rapid loss of flesh—the pulse small, concentrated, and often feeble, and this always succeeded by inflammation of the digestive organs if not combated in time. Some veterinary surgeons have confounded this malady with gastritis, complicated with inflation of the rumen, of which we shall hereafter speak; but this is an error. In gastritis the meteorization is only secondary, and to be attributed to the fermentation of the food contained in the paunch longer than the usual time, on account of the suspension of the rumination. In tympanitis from overloaded stomach, meteorization is frequently the first symptom, and to which we must also add the fulness and hardness of the paunch, for that organ is, secondarily at least, the seat and source of the inflammation of the organs of digestion.

"This variety of tympanitis resists the power of mucilaginous drinks—of ammonia—of ether—and even also of the puncture. The accumulated food, hard and dried in the rumen, forms certain pellets which, on account of their bulk, can no longer be returned to the mouth for a second mastication, for they are beyond the contractile force of the first stomach: it is absolutely necessary to cut into the paunch, and to introduce the hand, in order to empty it of its contents.

"I think that it is injurious to pour any liquid in considerable quantity, whether medicated or nutritive, through the incision made into the paunch, in order to extract the food with which it is surcharged.

"The paunch is not the stomach where the aliments are digested, that is, changed into chyle, or where the chyliferous absorption commences. Those which enter that stomach in a pulpy state must re-ascend to the mouth and become ruminated, not having been sufficiently comminuted by the first mastication. It is necessary for the accomplishment of this re-ascension that the paunch should contract itself in every way, in order to push the food towards the esophagean canal, whose lips open to receive and mould the alimentary ball, which passes through them and remounts to the esophagus. The energetic contraction of the muscles aid the ascension; but if the paunch, after having been cut or punctured, and inundated with fluid, contracts itself, whether by means of the stimulus of the substance which it contains, or to effect the ascension of the alimentary pellet when it is thus filled with both solid and fluid contents, is it not to be feared that some portion of the fluid and solid food will pass through the incision, and fall into the abdominal cavity? The presence of these substances in the peritoneal sac will invariably produce violent inflammation, and the death of the animal. Of this I have had many proofs, the particulars of which I cannot, for obvious reasons, now enter into."

Mr. Sotham, a spirited farmer, resident at Perch Lake Farm, Jefferson county, in the state of

too rapid extrication of gas,—we afford it a means of escape as it is extricated, and remove much of the irritation which arises from distension of the rumen.

New York, sailed in a vessel which left the St. Katharine's Docks on Wednesday, Aug. 19, bound for New York, taking with him as fine an assortment of cattle, sheep, and pigs as have ever been exported to America. The lot consisted of

Mr. Walker's Hereford cow, which obtained the prize at Oxford last year, and

A yearling bull, her offspring.

Four Hereford cows and seven yearling Hereford heifers, of the stock of Messrs. Hewer, of Northleach.

Twenty Cotswold rams, from the stock of the same gentlemen.

Two Durham cows, purchased of Mr. Lovell.

A half-bred Hereford and Durham, from Mr. Cothier.

Ten South-down ewes.

A cart stallion, and

A cart mare.

A sow and pigs, bought of Mr. Lovell, and

Sixty-five pigs of different sorts.

Mr. Sotham intends to make frequent visits to this country, for the purpose of purchasing cattle for export to America, and we trust he will receive the reward which his well directed energies demand.

IMPORTANT TO FLAX SPINNERS AND GROWERS.—We have been informed that the Government of Belgium, having it in contemplation to impose an increased duty upon the export of flax from that country—whence our spinners derive their chief supplies of the finest kinds of the article—sent a deputation to visit these kingdoms, with a view to ascertain the state of our flax and linen trades, and to report upon the expediency of the proposed tax. One of the deputation is a Member of the Belgian Senate, two others are Members of the Chamber of Representatives, a fourth is a banker, and a fifth an intelligent merchant. The deputation visited Belfast last week, and inspected the establishments of several leading manufacturers in the town and its vicinity, to whom they had letters of introduction. Their enquiries were particularly directed to the subject of Irish flax, the mode and extent of cultivation, preparing processes, manner of sowing the seed, profit to the grower, the quality, and the proportion used here, as compared with Flemish flax. On these and other points, the Commissioners received much interesting information, for which they expressed themselves deeply obliged. Of the specimens of Irish flax submitted to them, some were of a fineness to which they had not considered our inferior mode of culture, and our machinery for preparing it for the spinner, capable of bringing the fibre. We have reason to believe that the representations made to the deputation in Belfast, as to the impolicy of increasing the duty on the export of flax from Belgium, coupled with the information to the same effect they will acquire in England (whither they have gone) and Scotland, will go far to dissuade their government from a proceeding, the inevitable effect of which would be to limit the cultivation of that crop by their own agriculturists, and to offer a premium to our flax growers to devote such attention to improving the quality of the home-grown article, as must, ere long, render us independent of any other country, for flax of the finest descriptions; for there can be no doubt that such could be produced in Ireland as well as in Belgium, if the same care

were paid to soil, seed, and preparation. But that the proposed increase of duty would occasion for a time serious inconvenience and loss to our spinners of fine yarns, by restricting their supplies of the raw material, and consequently raising the price of the manufactured article, limiting its production and consumption, and throwing numbers of the industrious poor out of employment, it were almost to be desired that some such emergency should occur to awaken the linen and flax-spinning interests in Ireland, and through them the growers of flax, to the necessity of adopting such means for the extended cultivation of that important crop, and the improvement of its quality, as would place it out of the power of a foreign government to influence our supplies of the article. We have little fear, however, that the Belgians, who are shrewd people of business, will be so blind to their own interests as to impose a tax which would diminish their revenue, impoverish their farmers, and restrict a valuable branch of their commerce, without promising any equivalent advantage.—*Belfast Whig*.

LIQUID MANURE.

The use of liquid manure has often formed the subject of remarks and recommendation by those agriculturists who are conversant with the practice of foreigners on this point of rural economy; and attempts have been made by them to induce our British farmers to imitate their foreign brethren; but these attempts have hitherto proved in a great measure ineffectual, and the English system of dry or solid manure is still pertinaciously adhered to. There is, however, a pretty general opinion prevailing amongst the leading agriculturists that the subject is deserving of rather more consideration than has hitherto been bestowed upon it by the farmers of England; and that it is open to inquiry, whether the English or the continental mode of management of manures be superior.

For the information of those who may not be quite aware what is the foreign practice on this head, we may mention, that it is not only the custom in those parts of the continent which are most advanced in the science of agriculture, to collect and preserve in tanks and reservoirs every species of liquid which contains any enriching quality, but also to dissolve solid manure in water and other liquids, and to irrigate both arable and grass land with it. It is contended by foreigners, that the effects of this irrigation are far more beneficial than the application of the same quantity of manure in a solid form; and it must be owned there is ample testimony, that most productive crops are obtained under this system.

In the consideration of this practice, it is essential to separate it under its two natural heads:—1st, the use and preservation of manure which is already in a liquid shape; and 2ndly, the reduction of solid dung into that state. We shall, in the first place, offer a few remarks upon this latter mode of management.

The principal objection which will strike the mind of an English farmer, is the vast increase of carriage which must be occasioned by it. It has been the constant aim of English agriculture to diminish road work, and to condense manure into as small a compass as can be attained without deteriorating its strength; and we must say, we think the principle a sound one. The advantages of bones from the mere fact of their portableness, will at once

occur to every one as an instance in point. The foreign practice of converting solid manure into liquid, is in direct opposition to this principle. But we are met in this objection by the assertion, that foreigners procure most abundant crops by the practice, and it cannot be denied that this is true. In the first place, however, we ought to set the additional leading against the increase of produce; and we are not quite sure that with the high rate of labour in England, much augmentation of profit would then be shown. And supposing it were, there are other points which strike us in the case. Liquid manure cannot be so lasting as solid dung, and though the first crop will be greater from it, for the simple reason that it is in that fluid state which is requisite for vegetation, it would appear quite clear that the second crop will meet with less sustenance in the land. Aware of this, the foreigner applies more tillage ere he sows a second crop; and it is thus evident that he is adopting a system of high manuring, which cannot fail of producing abundant crops. Again, in many of those districts where this practice of liquid manure seems to confer such benefit, the climate is of a drier nature than in England, and there the application of a fluid to the land is eminently advantageous. With our humid climate we have too often more moisture than is desirable; and the solid manure is rarely injured, when once in the ground, by drought; nor kept from a dissolution quite as rapid perhaps as vegetation requires it.

Upon these grounds, we think that the English system of solid manures is far sounder in principle, as applicable to the climate under which we live; and we see no cause why our countrymen should attempt to imitate the foreign farmer. But in the economy and application of the manure which is already in a liquid state, it certainly strikes us that the British agriculturist is far behind his continental brethren.

No one who is aware of the value of liquid manure, can fail to notice with regret the waste of it which is to be seen in almost every farm-yard in England, the drainings from the fold, from the stables, and the sheds being allowed to flow away without the slightest attempt to collect and apply them to the land. It is obvious that a source of fertility is here unheeded and unknown. The more frugal, and in this instance more skilful foreigner, collects in tanks such valuable materials, and with the aid of water-carts, irrigates his farm with them. This practice we earnestly and strongly recommend to the English farmer. We are aware that many will meet us with the objection, that the cost is greater than the thing is worth; but to this we oppose a decided contradiction. From actual observation of the system we advocate, we are enabled to assert that the expence is trifling, whilst the advantage is so great that it needs but a fair trial to bring it into general use.

We would recommend that all the stables, sheds, &c. should be made (as indeed is generally the case) to drain into the fold yard; that all liquids of every kind coming from the house should also be conveyed to it; and that a tank should be constructed to receive the whole of the drainage from the fold, which will include the rain water falling upon and passing through it, but bringing, however, a strong admixture of manure. This tank, as often as it gets filled, should be emptied by means of a pump, and carried in a water cart upon the land. There is upon all farms, where it can possibly be attained, some grass-land adjoining the homestead, which it is essential for the sake of convenience, to keep in good health;

and it seems to us that the liquid manure cannot be better applied than for this purpose. We have heard it asserted upon authority upon which we place great reliance, that on a farm of 200 acres where the ordinary number of stock is kept, sufficient liquid may be obtained by this plan for manuring well ten acres of grass land yearly; and we need not point out that this is a great and desirable advantage. The labour of the operation is comparatively of slight moment, because it is performed far more rapidly and expeditiously than those who have not witnessed it perhaps imagine; and it is, moreover, done by the farmer's own horses and men without additional assistance.

The first expences of starting this system are, however, to be considered. We have already said that they are not of great amount; and we will now proceed to point them out.

There are required a tank, a pump, and a water-cart. The cost of a tank capable of containing 50 hogsheads, which we apprehend would be large enough for any farm, would be about eight guineas, the walls to be bricked and cemented, which is the most durable construction. We of course suppose in this calculation that in the excavation of the pit there is no rock or very hard substance, as this would increase the expence. A pump, supposing a new one to be put down, might be procured for about four or five pounds; and a water-cart for about eight or ten pounds. The whole expence would consequently be from twenty to twenty-five pounds;

and with this first outlay a farmer would be yearly able to manure from his own fold-yard a great additional number of acres, without a farthing more expenditure in labour, or increase of his bill with his tillage merchant.

For these reasons we urge the subject on the earnest consideration of our agricultural readers; and we especially solicit the attention of those who are in the position of landlords, because we think that the first effort to effect this improvement ought to be made by them. The construction of the tank, as it will form one of the permanent buildings of the homestead, ought clearly to be defrayed by them; and if the tenant finds the pump and cart, the expence will fall lighter on either party. But whether the first impulse come from the owners or occupiers of land, the sooner it be made the earlier will the profit be assuredly felt.

Although this may be copying from foreigners, we are not advocating a system which is altogether unknown even in our own neighbourhood. We are informed that it is not only fully, but successfully, adopted on the farm of E. B. Beaumont, Esq., of Finningley Park; and we would urge upon those who are slow to credit the advantages which we point out, to inquire for themselves what have been the results of its adoption; for we feel assured that the more the subject is investigated, the more the accuracy of our views will be apparent to them.—*Doncaster Chronicle*.

MOODY'S NEWLY-INVENTED PATENT ROOT-CRUSHER.

The subjoined drawing represents a machine for crushing Swedes, and all bulbous roots, invented by Mr. E. Moody, Maiden Bradley, Wilts, upon whose farm its beneficial effects, both as regards economy in food, and the nutrition afforded the sheep and cattle, &c., have, it is said, been fully proved.

The machine only requires the attention of a boy, and with the power of a small pony will crush sixty bushels in an hour, reducing the roots to a pulp, which, mixed with a proportion of chaff, is eagerly devoured both by sheep and cattle, and prevents waste. A machine on the same princi-

ple, worked by hand, requires the power of but one man, and will crush fifteen bushels an hour, and might be used for grinding apples.

The undermentioned gentlemen, with many others, have one of the machines in use, and recommend it to the attention of farmers.

T. H. H. Phipps, Esq., Leighton House; J. W. Peters, Esq., South Petherton; H. Miller, Esq., Frome; Mr. G. Parsons, West Lambrook; Mr. Joseph Harding, Rodmead; Messrs. Jefferys, Maiden Bradley; Mr. Thomas Burge, Baycliff; Mr. Lush, Kilmington; Mr. Chandler, Stockton; Mr. Attwater, Britford.

WESTER ROSS FARMERS' SOCIETY.

It will be seen, from the subjoined report of the meeting of the "Wester Ross Farmer's Society," that the proceedings must have been of a very interesting character. One of the most prominent matters, was the signing a petition to be presented to the Highland Agricultural Society, for the establishment of "experimental farms" throughout Scotland, and another to the Royal Agricultural Society of England for the like cause, we perceive, *throughout* England. The term *throughout*, seems to contemplate *several* experimental farms in each division of the kingdom. Now we should esteem it an obligation, if some one of the gentlemen who signed the petition, would favour us with a detailed statement of the amount of capital, the stock, implements, &c., requisite for "one" such establishment. As a model of such a statement we would refer to the "Report of Whitfield Example Farm," by John Morton, given in the appendix to the last edition of his book on soils, and which will also be found in the "Farmer's Magazine" for May last, page 415. On the subject of fallowing, the Chairman, Sir F. Mackenzie, gave it as his opinion that fallowing might be wholly dispensed with, if sufficient attention were paid to weeding the land; and that crops of beans, potatoes, tares, and clover, preparatory to wheat, were better than fallow. In this opinion we cannot concur with Sir F. Mackenzie; we believe that fallow may be dispensed with in a great many situations in which it is now used: in fact in many districts, even where the land is light, the occupiers seem to think it almost necessary to let the weeds and grass grow in abundance, that they may have a fallow. Somewhat in the same spirit with the farmer, who felt at a loss to know how he should find fodder for his young cattle in the ensuing winter, the season having been so fine as to prevent his having any inferior hay. But we know that we shall be borne out, by the best practical farmers, in stating, that there are some soils which need, periodically, additional cultivation and exposure to the atmosphere, not merely for the purpose of destroying weeds, but of rendering them more friable and increasing their fertility.

On Friday the 7th August, the Wester Ross Farmers' Society held its quarterly meeting at Dingwall, when a committee was appointed to select a salesman of their own for the London market, and after the routine business of the forenoon, a large party sat down to an excellent dinner, at the Royal Hotel, Sir Francis Mackenzie in the chair, H. I. Cameron, Esq., croupier. After the usual toasts were given and drunk, the Secretary read the petition to the Highland and Agricultural Society, for the establishment of experimental farms throughout Scotland, which was unanimously approved of and signed by all present; and it was also resolved to petition the English Agricultural Society on the same subject, convinced as they were of experimental farms being of paramount importance. Thereafter a long and interesting discussion took place, on the best preparation for sowing and obtaining a crop of wheat, which was begun by Mr. Monro, who quoted various parts of Sir John Sinclair's works on agriculture,

and recommended fallow, early and hardy varieties of seed, the use of blue vitriol as a preventive of smut, and guarding against the indiscriminate use of fresh dung as having a tendency to produce mildew. He also recommended the use of salt, at the rate of 6½ bushels per acre. Mr. Ross considered beans manured the best preparation for wheat in this country. Mr. Denman concurred with Mr. Ross as to the value of beans, but stated, of course grass seeds could not be sown after them, and that fallow was necessary on all soils occasionally, excepting those of a light, sandy nature. Mr. D. added, that the mode of preparing fallow in this country was very objectionable; he recommended dunging early, forming the ridges of 36 feet instead of 18, and drilling in the seed with the drill machine at the depth of four inches. For rust or mildew Mr. D. thought no remedy could be found, but that smut arose solely from want of care in the pickling of the seed. Major Mackenzie thought potatoes the best preparation for wheat, and concluded with a number of useful observations, drawn from long experience, and confirmatory of the remarks made by preceding speakers. The subject was now taken up by the chairman, who stated that he wholly objected to fallows as being only necessary when the attention of the farmer was not sufficiently turned to weeding his crops, and that he considered fallows for wheat by no means so valuable as beans, potatoes, tares, and clover; that in Essex they now invariably took barley and grass seeds after fallow, instead of wheat, as formerly; he felt convinced that the green crops would always pay more than the cost of cleaning the land, whilst the working of fallow was money wholly sunk. Sir F. then alluded to drilling of wheat, and stated that from his own experience there was a decided advantage in drilling; that on a discussion lately at one of the principal farmer's society meetings in Essex, it was finally agreed that broad cast sowing of wheat was out of the question, whilst the number in favour of drilling and dibbling were equal. Sir F. however having tried dibbling on his farm in a pretty extensive scale, thought it was unsuited for this climate, for reasons too long to detail. Sir F. stated that he was preparing a drill after the one invented by Mr. George, of Norfolk, a distinguished agriculturist there, which drills the seed at 14 and 4 inches, thus leaving room for weeding the corn at all stages of its growth, and thus having it perfectly clean for the following turnip crops; with regard to weeding he stated that Mr. George having left half a field unweeded, and cleaned thoroughly the other half, there was an increase of 2 qrs. per acre on the weeded alone, that on the dirty half. Cleaning and weeding Sir F. considers indispensable, for the land could give but a certain quantity of anything, and if half were weeds, only one half of the crop of corn would be produced. Sir F. quite agreed with Mr. D. as to the size of the ridges, and said that furrows should be wholly abolished, and that there was no necessity for furrows if the land were properly drained, and that if rain water was dreaded, it ought to be saw-furrowed with the spade. As to the best preparation crop for wheat, beans and potatoes he certainly considered the most suitable in this country. In the Lothians much was sown after turnips, fed off with sheep, which had not answered here, but that he had a first-rate crop this year after Swedes, taken up and stored in November. Early sowing he considered injurious, the best time was the first week in November, for though it might look stunted in winter it invariably turned out most productive under the sickle. Rolling is most important, as is proved by the best wheat ears being always by the side of a

foot-path which is well trampled on. Fresh dung he considers injurious, as it produces rank leaves, a small ear, and a tendency decidedly to mildew. He has been assured by Mr. Franks, one of the most successful wheat growers in Essex, that the most profitable way of applying dung was by laying it on the young clover in winter, by which means an immense weight of hay was produced and a very superior crop of wheat afterwards, from the dung being old and completely absorbed by the earth.

Sir F. recommended the use of the grubber as one of the best novel inventions of the day, doing the work of 2, if not 3 ploughs in cleaning the land from weeds, while at the same time, it did not too much pulverise the soil. He cautioned against the over draining of land and thereby depriving it of its tenacity, which was so favorable for the growth of a heavy crop of wheat. He concluded by adverting to the choice of seeds suited for this climate, saying, that so far as he could yet judge from the appearance of his experiments with various kinds of wheat on his farm this season—Golden Drop, Sugar Pearl, and Suffolk thickset: Tunstal thickset was the only one rusted, and therefore unfit for this climate, though otherwise a beautiful variety of wheat. Sir F. then thanked them for the attention paid to his lengthened remarks, and invited those present as well as any agriculturists anxious to see the results of his experiments, to visit and inspect his farm on Friday, the 21st current, when he should be himself present, and when he should be obliged if his visitors pointed out or suggested any remedies for errors which they saw he had committed in his cropping and improvements. —*Communicated. Inverness Herald.*

ON THE USE OF LINSEED.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—I imagine your correspondent "Lintseed," instead of being "convinced" must be only of *opinion*, that as the fattening properties of Linseed consists in the oil it contains, it may be prepared in some way, and rendered more advantageous in fattening cattle than by giving the cake, which is the refuse.

Some of your readers probably may have made sufficient trial in various ways (for the idea is not a new one), and may have discovered a method, and proved to a certainty, that it may be so prepared. As to cake, much depends upon its genuineness, and the state it was in at the time of using. Whether it is from pure linseed and lately crushed, or whether it may not contain an admixture of certain oleaginous seeds, which, though they contain a portion of oil, their husks contain very little nutriment, old turnip seed, rapeseed, and others, being occasionally used by the seed-crushers; also, when cake is old, especially foreign, and has become mouldy, it is brushed over with linseed oil, and appears fresh to the eye, but cake thus treated is readily detected by an experienced person. Experiments to ascertain the relative merits of the different methods, require to be made with much more accuracy than is usually bestowed on them, before a satisfactory conclusion can be drawn from them. Linseed as a food, in consequence of the oil it contains, is generally, at first, loathsome to cattle, and some are longer than others before they can overcome this effectually. Breeders of stock should give it their calves in small quantities at first, with

a small portion of salt, and when they have once acquired a taste or relish for it, it never leaves them, and in whatever way linseed is afterwards given, their relish for it causes them to consume it with avidity, and its effects are presently seen.

I have given linseed to cattle after being bruised, after boiling to a jelly, mixed with barley-meal, bean-meal, cut chaff, hay, &c.; cut meat mixed with a portion of the pure oil. It is beneficial given by any of these methods, but subject to great waste without considerable cure; perhaps steamed with other food may be the best among these methods, and least liable to waste. But as far as my experience has gone, that if linseed is bought at 50s., and good cake at 13l. per thousand, that the cake is to be preferred, as being cheaper, less liable to waste, and much less trouble in using, and better suited to the appetite of the animal, than by any preparation of the seed alone.

I am aware these observations do not contain exactly the information sought by your correspondent, and that the experience of some of your readers will cause them to differ in opinion with me. If so, I hope they will give "Linseed" and your other readers the benefit of their experience, as cake, though very efficient, is an expensive article in fattening stock.—Permit me to remain, Mr. Editor, your obedient servant,

A YEOMAN OF KENT.

SIR,—I observe in your last number an inquiry as to the best mode of preparing linseed for fattening cattle. If four bushel of bran and two bushel of short be well mixed with four bushel of linseed, and ground altogether (on a pair of black or cullen millstones), they will make a rich, nutritious feed, equal, if not superior to oilcake. The bran and shorts not only prevent the millstones from clogging, but absorb the oil that comes from the linseed.

Yours,

A RUTLAND GRAZIER.

SIR,—In your paper of the 31st ult., a correspondent requested to be informed "the best method of preparing linseed for the feeding of cattle and sheep." I beg to suggest the following, which is very simple, and can be tried without any expense or risk:—To about four bushels of pollard mix one bushel of seed, and send it to the mill to be ground. I may not have stated the exact proportions, but this the miller will soon discover, as the seed being of a gelatinous nature, would clog the stones, and thereby prevent them from working freely. If the above method is found to answer, I would recommend it to be kept in small quantities, for if laid in a large heap spontaneous fermentation might take place. Should you think the above worth publicity, you are at liberty to do so through the medium of your valuable Journal.

I am, Sir, your obedient servant, J. B.
Long Melford, Suffolk, Sept. 9.

NEW PATENTS.

John Sanders and William Williams, of Bedford, ironfounders, and Samuel Lawrence Taylor, of Old Warden, Bedford, machine maker, for improvements in ploughs.—Aug. 3.

Downes Edwards, of Surbiton Hill, Kingston, Surrey, farmer, for improvements in preserving potatoes and other vegetable substances.—Aug. 8.

Baron Chas. Wetterstedt, of Limehouse, for improvements in preserving vegetable, animal, and other substances, from ignition and decay.—Aug. 11.

Y 2

REPORT OF THE COMMITTEE OF THE HOUSE OF COMMONS ON BANKS OF ISSUE.

The Select Committee appointed to inquire into the Effects produced on the Circulation of the Country by the various Banking Establishments issuing Notes payable on demand; and to whom the Petitions presented this Session relative to Currency and Banking, and the reports of former committees on banking were referred:—Have considered the several matters referred to them, and have agreed to the following Report:—

Your committee, in prosecuting the inquiry entrusted to them by the House, have examined evidence, and called for various accounts, for the purpose of elucidating the management of the affairs of the Bank of England since the last renewal of its charter, and also of ascertaining the amount of the circulation of the other banks issuing notes payable on demand, throughout the United Kingdom, during the same period.

Accounts containing minute information, upon every point, which it appeared to your committee desirable to call for, relating to the Bank of England, have been furnished by the bank.

The private and joint-stock banks in England and Wales have sent, through the Stamp-office, returns of their issues, from week to week, for the last six years.

A similar account has been furnished by the various banks in Scotland, which information is the more valuable, from its never having hitherto been laid before Parliament.

The Bank of Ireland has sent in returns of its liabilities and assets for every week during the same period as has been required from the Bank of England.

The private and joint-stock banks in Ireland have furnished accounts of their issues similar to those of the private and joint-stock banks in England.

Your committee consider it to be only just and due, both to the Bank of England and to these various parties, to state that the greatest readiness has been shown by them in furnishing all the accounts which your committee have required.

With regard to the evidence which your committee have taken, they, in the first instance, examined several witnesses, who stated generally the evils which in the last few years had, in their opinion, been caused by the management of the circulation. They then called before them two of the directors of the Bank of England, who have given detailed information as to the management of the affairs of the Bank. It was their intention to have proceeded in the next place with the examination of such witnesses as might have afforded similar information respecting the management of other banks of issue. Towards the close, however, of the examination of the witnesses on the part of the Bank of England, it became evident that it would be impossible during the present session to conclude the evidence of the witnesses connected with the other banks of issue; and under these circumstances your committee thought it more advisable to postpone the examination of this class of witnesses, and to summon one or two persons who were known to have paid particular attention to the management of the Bank of England, and whose evidence upon this point it was, therefore, desirable to have before them.

Your committee trust that this statement will sufficiently account for their not reporting any opinion to the house on the main subject of their inquiry; and they feel that they shall best discharge their duty by merely submitting to the House the evidence which they have taken, although they are fully aware of the imperfect character of that evidence, arising from the circumstance of their having been prevented, by the approaching termination of the session, from examining witnesses whom they had proposed to call, on other important branches of their investigation.

They also submit, in the Appendix, the accounts to

which they had before referred; in which, as well as in the evidence, they feel confident that much valuable information will be found upon the subject of their inquiry; a renewal of which they would earnestly recommend to the early attention of the House in the next session of Parliament.

In the course of their inquiry into the management of the affairs of the Bank of England, the attention of your committee has necessarily been directed to the principle by which it was stated in the evidence taken before the Bank Charter Committee in 1832 that the Bank was in ordinary circumstances guided in the regulation of its issues. This principle has been re-stated to your committee, in Mr. Horsley Palmer's evidence, in the following questions and answers:—

1142. Chairman: As it was mainly your evidence given before the Bank Charter Committee in 1832 which contained the exposition of the principle by which in ordinary times the Bank is guided in the regulation of its issues, will you have the goodness to re-state that principle to the committee?—I will re-state it in as nearly the same words as I can. The principle, with reference to the period of a full currency, and consequently par of exchange, by which the Bank has been guided in the regulation of its issues, always excepting special circumstances, has been to retain an investment in securities, bearing interest, to the extent of two-thirds of their liabilities, the remaining one-third being held in bullion and coin; the reduction of the circulation, so far as may be dependent upon the Bank, being subsequently solely affected by the foreign exchanges, or by internal extra demand.

1143. Did you not also state it as desirable, in ordinary circumstances, that the securities should be retained at nearly the same amount?—Yes. The object of retaining a fixed amount of securities by the Bank at the period alluded to, and continuing it afterwards, so far as may be practicable, is to throw the action of the increase or decrease in the circulation upon the public, with reference to the state of the foreign exchanges, in the import or export of bullion.

1144. Are the answers which you have now given a fair exposition of the principles upon which the conduct of the bank has been regulated since the period of the renewal of its charter?—I should say certainly, always taking into consideration the extraordinary circumstances that have intervened.

Your committee would upon this point wish to call the attention of the House to the evidence of the two Bank directors who have been examined, Mr. Horsley Palmer and Mr. Norman, from which it appears that in several instances since 1832 the rule then laid down has not been adhered to; and doubts have been expressed as to the soundness of its principles, as applicable to the Bank of England, from its mixing up deposits and circulation. It appears, however, at the same time, from the following questions and answers in Mr. Norman's evidence, that the Bank directors conceive that this rule has received some sort of legislative sanction, in consequence of which they feel bound to adhere to it as nearly as circumstances will permit, and that on a particular occasion they were fettered by this impression:—

1890. Referring to the accounts of the bank, does it not appear that the drain, in the first quarter of 1839, fell almost entirely upon the deposits of the bank, and in no degree upon the circulation?—I believe that it fell almost wholly upon the deposits.

1891. The effect, then, which you anticipated in a former part of your evidence, from any reduction of circulation during a drain, did not take place during that quarter?—No, not to any considerable extent.

1892. Would it not have been expedient that the Bank should in that quarter have taken some measures for the reduction of the circulation, looking to the rapid drain which was going on?—The Bank considered itself at that time bound to adhere as nearly as it could to the principle of holding a fixed amount of securities, that principle having been to a certain extent recognised by the legislature and the public; but if I am asked now, with my present experience, whether it would not

have been wise in the Bank to have taken earlier measures, I must say that I think it would have been wise so to do.

Without entering into the question either of the soundness of the rule, or of the degree of sanction which it may be supposed to have received from the Legislature, your committee are clearly of opinion that such an impression on the part of the directors of the Bank of England ought not to prevent them from adopting any other principle of management which, after their further experience, and upon mature consideration, they may consider to be better adapted for the primary object of preserving, under all circumstances, the convertibility of their notes.

Aug. 7, 1840.

JOINT STOCK BANKS.

The committee of deputies of the joint-stock banks have issued a circular report of their proceedings since the 4th of June last, when the general meeting of deputies was held. This document communicates nothing of any special novelty beyond the fact of preparations for taking the field vigorously in the ensuing session of Parliament. It was before known that the examination of Mr. Stuckey and Mr. Gilbart on behalf of the banks was postponed till then, on account, as Mr. Charles Wood, the chairman of the Bank committee of the Commons' House, very fairly stated, of the length to which the examination of some of the witnesses had extended, and the expediency of bringing "towards a conclusion the evidence relating to the Bank of England," rather than to "commence upon evidence relating to country issues," in which from the approaching termination of the session little progress could of course be made. It might seem rather partial and injurious to the joint-stock banks that the evidence so far, from taking part in which their advocates were excluded, should be prematurely published because of course not in a complete form. But we are inclined to think the advantage of this in one respect will more than compensate the prejudice, if any, which might result to their disavowal by the publication of incomplete or *ex parte* evidence. For now the whole of the body will have the evidence before them in the most approved form, and with ample time to digest and dissect it. The late amendments in the law of joint-stock banking with respect to suing or prosecuting partners criminally are referred to with satisfaction. The contemplated course of future action is thus alluded to:—

"With a view to ascertain the parliamentary strength of the joint-stock banks, the committee of deputies will feel obliged if you will have the goodness to send them the names of any members of Parliament who may be directors or shareholders in your bank, and also of any other members whom you know to be friendly to the cause of joint-stock banking.

"The committee will also thank you to send them the names and addresses of any persons whom you can recommend as proper witnesses to be examined on behalf of the joint-stock banks, before the parliamentary committee at the commencement of the next session.

"The committee would also further impress upon you the necessity of explaining to those members of Parliament with whom you are acquainted the true principles on which the joint-stock banks are founded, and the present imperfect state of the law—of distributing throughout your district these publications that contain the best defence against the attacks of our opponents—and of co-operating powerfully and perseveringly in any parliamentary struggle in which we may be compelled to engage."

ON THE HOOSE IN CALVES.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—In looking over the Mark Lane Express for August 31, I find a letter addressed to you, signed by D. J. L., soliciting information as to the best remedies for *Hoose* in calves, (not *hoove*, as the *then* editor of the Veterinarian, Mr. Youatt being ill, has very inadvertently and erroneously styled as the subject upon which my communication treated) and in which he states my having recommended lime water alternated with a solution of salt, but that I have not stated the quantities. The quantities, I think, are given in a former paper of mine, and which has probably not caught D. J. L.'s eye; however, as this is a subject particularly interesting to every farmer and owner of stock, with your permission I will forward from time to time the respective papers, as published in that valuable periodical, the Veterinarian, if you will not consider them as occupying too much space in your valuable paper.

I do not hesitate to assert that these simple remedies are quite a specific for this affection, so much more peculiar to the cloven-footed tribe than any other species of animals, and attended with a great fatality and consequent loss of capital to the farmer not easily appreciated. I have found that half a pint of lime water administered every morning to a calf, and a dessert spoonful of salt every evening, dissolved in half a pint of water, generally restores the animal in the course of a fortnight or three weeks. Where Twinters are affected, the dose is a pint of lime water and a table spoonful of salt. In sheep and goats, the dose is a quarter of a pint of lime water and three tea spoonfuls of salt. In deer, the doses are the same as in calves. The animals should be turned out into good sound pasture land, and where the water is either a pure running stream or where it is contained in a marl-pit. I have generally found those situations most liable to this affection where the land is peaty, lying low, and where the water runs through a boggy or peaty strata.

In extreme cases of *hoose*, where there is immediate danger of suffocation, there is no time to be lost in performing the operation of tracheotomy, which is done by making a longitudinal incision, from three to four inches long, down the front of the windpipe, midway between the point of the chest and the upper portion of the windpipe, cutting right down to the latter and laying it bare, so as to excise a square portion of two of the rings out; when there are no proper tubes at command to insert into this opening, take a large circular piece of cork, cut out a circular hole in its centre, insert it between the lips of the wound so that it may lie upon the surface of the windpipe, and fasten it down by securing a fine piece of gauze around the neck; this will be the means of keeping foreign bodies from getting into the trachea, and afford you time to get your remedial measures into fair play.

Often, individuals are so placed as not to have even these conveniences at command; under such circumstances, the animal will not generally take any harm by leaving the wound open altogether. As D. J. L. has made a general appeal to the profession, I trust I shall not be out of place in having, for one, responded to his call.

I remain, dear sir,

Your's most respectfully,

THOS. MAYER, SEN., V.S.

Newcastle-under-Lime, Sept. 8th.

ON AGRICULTURAL SOCIETIES AND FARMERS' CLUBS.

Actuated solely by the desire of elevating the position of the farmer, and of promoting improvement in agriculture by the most effective means, if at any time we should offer any remarks which may *seem* to throw an obstacle in the way, we trust we shall stand acquitted, should our views be erroneous, of a wish to prejudice that cause, which we most sincerely desire to serve. We this day lay before our readers a long report of the proceedings at a meeting of the "Warminster and South Wilts Farmer's Club," by which a more rapid progress has been made in carrying out the good objects contemplated, than by any other local institution of the kind, the proceedings of which has fallen to our lot to record. Before we proceed, however, to notice more particularly any part of the proceedings of the day, we will hazard one or two remarks upon the objects and constitution of Farmer's Clubs. Agricultural Societies have been long established in this country, "Farmer's Clubs" are, with one or perhaps two exceptions, of but very recent date. The difference in name alone, naturally leads to the conclusion that the nature of the proceedings of these institutions are different, although the ultimate object may be the same. The objects to which the attention of Agricultural Societies generally have been directed are, by competition for prizes offered, the improvement of the breed of cattle of every description, of agricultural machinery, and of the operation of ploughing, and the encouragement of deserving agricultural labourers. To these in some cases have been added, improvement in the different kinds of grain, improved cultivation, draining land, &c. Such have been, and such we hold to be strictly the legitimate objects of "Agricultural Societies or Associations." The objects of a Farmer's Club may be described as twofold, namely, improvement of the *mind* of the farmer himself, and improvement in the *practice* of his occupation. We cannot better describe the objects of Farmer's Clubs, than by repeating here an extract from the prospectus of the Isle of Thanet Farmer's Club, quoted by our excellent friend, R. B. Harvey, of Harleston, in his valuable essay, "On the advantages of Farmer's Clubs," which appeared in the *Farmer's Magazine* for December, 1839:—

"The formation of Farmers' Clubs is a new and interesting feature in agricultural history. By means of these institutions much valuable information is diffused; different modes of cultivation are compared and their results ascertained; improvements are suggested and made public; and the interchange of thoughts, opinions, and observations, promotes good feeling and in various ways exercises a beneficial influence. Among the objects sought to be attained by Farmers' Clubs are the following:—to ascertain the nature and qualities of the soils and subsoils of the district; to inquire into the comparative value of different sorts of manure; to test by experiments alleged improvements in cultivation, in agricultural implements, or in the management of stock; to discover the most profitable varieties in corn, seeds, or roots, and the most advantageous rotation of crops; to collect information respecting the state and progress of agriculture, by corres-

pondence, by establishment of agricultural libraries, and by such other means as may be deemed expedient; in a word, to advance the interests of agriculture in every possible way—reducing theory to practice, and throwing the light of knowledge and science over the most useful and important of the arts of life."

Upon this, Mr. Harvey pertinently remarks:—

"The allusion to agricultural libraries in the above prospectus, brings me to a part of the subject which, although the last mentioned, is not amongst the least of the advantages derived from Farmers' Clubs. It has been impossible for persons engaged in agriculture to procure any books treating on that science but at a heavy outlay of money, purchasing them at their sole expence; as should they have the wish or opportunity of joining the Book Club in the nearest market town, they will not find in it works treating on farming; and yet, if agriculture is to emerge from the stationary position in which from a want of the application of science it has so long been placed, how can this be accomplished but through the medium of books, and more particularly of periodical works, which by placing before us the suggestions, the experiments, or the practical knowledge of other cultivators, enable us to benefit by such information, and to pursue our own improvements with much better prospects of success?"

A Farmers' Club may, in other words, be called a "Mutual Improvement Society," to which each member contributes his portion for the benefit of the whole, where information is not so much gained by what is *seen* as what is *said*; whilst at the meetings of Agricultural Societies, more is learnt by what is *seen* than by what is *said*. Now by a reference to the proceedings of the "Warminster and South Wilts Farmers' Club," it will be remarked that the objects to which attention is directed, are those of an Agricultural Society; and it appears to us that the name of "Agricultural Society" would be much more applicable to it than that of "Farmers' Club." We believe it is intended to unite the objects of a Farmers' Club by having meetings, discussing agricultural subjects, establishing a library of agricultural works, &c., but in our opinion the union of the two objects will much prejudice the "Club." In the first place, a club should not be too numerous, the "Warminster Farmers' Club" we believe already numbers above one hundred members. Whenever the number of members attending a club are large, there will be generally a select few ready speakers, who will be first in taking part in the discussion, and opportunity will not be afforded to those who are more diffident, of offering their opinions. Now we are by no means ambitious to make all the farmers orators, but an exercise of this kind rouses the mental faculties, sharpens the understanding, and moreover the real bearings of the question under discussion, and its merits will be more correctly elicited by having the opinions of many rather than of a few individuals. There is another point in reference to "Farmers' Clubs," upon which we may perhaps entertain a peculiar opinion, which is, that the members should consist almost, if not altogether, of *practical farmers*, men who if they do not absolutely depend upon their business for support, still follow the pursuit for the purpose of making a profit by so doing. Influential

landed proprietors should be members of, and do their utmost to support Agricultural Societies; should encourage and render assistance in the establishment of "Farmers' Clubs" by contributing to the formation of Agricultural Libraries, &c.; but we do not think that their presence at the meetings of the Clubs will in any wise tend to promote the objects for which they are established. We make these remarks with the most sincere desire to promote the establishment and good organization of institutions, which we believe to be peculiarly calculated to advantage the practical farmer. And we shall be anxious to learn how far these opinions meet the views of those who take an active interest in these institutions.

To return to the proceedings of the "Warminster and South Wilts Farmers' Club," they are of a very interesting character. The prizes for the encouragement of deserving agricultural servants were numerous considering that it was the first meeting, and the history of several of parties who received the reward of meritorious service, is such as to excite a lively sympathy, to afford an excellent example, and to redound highly to the credit of both master and servant. On this head the county of Wilts may safely challenge a comparison with any county in England. The instance alluded to by the Chairman in his excellent address, that of a man who "receiving wages varying from 8s. to 10s. per week, had in the course of four years and three quarters, contributed not less than 30*l.* 17*s.* to the support of his aged parents," deserves to be recorded.

A deserving tribute was paid to the exertions of Mr. Ravenhill, in aiding to establish the club, and which we remember to have noticed when the prospectus for its formation was first announced. Speaking of agriculture, Mr. Ravenhill observed:—

"The cause of agriculture was the cause of mankind, and it was a source of pleasure to know, that in proportion as they improved its system, so in proportion did they advance the interests of the labourer. A spirit had been kindled in its support, which had extended from one end of the country to the other. Agriculture was no longer looked upon as an art, it now ranked among the sciences; and as agriculture itself became elevated, so would those be who pursued it, both in intelligence and station. He believed the Royal Agricultural Society contemplated by its rules a better system of education for the rising generation in the agricultural interest, and offered rewards in certain cases. He was not aware whether anything of the kind had been thought of in Wilts; but as a stimulus to study, he should be happy to give a prize of 5*l.* next year, to be competed for amongst the sons of members of the society, (being farmers), who should pass the test of examination in the study of Sir J. Herschel's "Natural Philosophy"—a most useful little book."

We having frequently expressed our opinion on the importance of an improved system of elementary education for youths who intend to pursue farming as the business of their lives, and we earnestly hope that the attention of the Royal Agricultural Society will be directed to the subject. It affords us very great pleasure to find that a person, so well qualified to form an opinion on this subject as Mr. Ravenhill, coincides with us,

and we believe, at least so far as has come under our knowledge, we may state, that the prize just offered by Mr. Ravenhill to farmer's sons, for superior knowledge in any department of science, is the first announced at a meeting of an Agricultural Society. We hope to see it speedily followed by a prize for proficiency in the knowledge of agricultural chemistry.—*Mark Lane Express.*

NITRATE OF SODA AS MANURE.

TO THE EDITOR.

SIR,—I believe I am the first individual who used the nitrate of soda as a manure, and have always found it answer beyond expectation. I will not refer to former years, but will answer your correspondent's question as briefly as possible, and probably the experience of the last year will satisfy him. I use it as a top dressing, and applied 1 cwt. to the acre to my wheat, when the plant had suffered much from the wet or the wire-worm. It was surprising to see how soon the wheat recovered its healthy appearance and the wire-worm quite left it, and I should think I have more than an average crop. I have also used it without any manure, upon eight acres of turnips, and they are remarkably fine, better than those where I have used the yard-dung. The nitrate was used broad-cast, and sowed with the seed in a few days afterwards. I used it last year with turnips, and the fly forsook them immediately. The barley is very fine where I used the nitrate. My farm is stony land, with a substratum of chalk, but I believe it succeeds upon all soils. I have generally used it as soon as vegetation begins to feel the influence of the spring. I shall be very happy to give any further information, and remain, Sir, yours truly,

JOHN BURROWS.

Elmhurst, Great Missenden, Bucks, Aug. 28.

NOVEL MODE OF WINNING HAY, as practised by Mr. Jos. Gibson, upon a high-land farm at Dowsgrill, near Greta Bridge, Yorkshire.—Of course, in such situations, the crops are generally lighter than they are upon the lowland farms, where the system might not answer so well. There being no labourers living near to Dowsgrill, Mr. Gibson's practice is, to strew the grass in the usual way, and when it is sufficiently dry for turning, a flock of country or half-bred sheep, are put into the field, and driven slowly along by a shepherd and his dog, making regular turnings, until the whole of the field is traversed over; by this means, if the weather is favourable, he can have his hay ready for putting together on the third day after the cutting of the grass. Such is the case this year. This method may, at first, appear rather ludicrous, but Mr. G. has practised it with success for some seasons; I saw the operation a few days ago, and I can assure your Highland friends in particular, that they would be highly satisfied were they to try the effect. From the sagacity of the dog, which has been accustomed to his work, the business appeared to be effected with the least possible trouble.—*From a Correspondent.*

SHOEING HORSES is rendered needlessly difficult to the farrier, and suffering to the animal, by being performed when the horse is fresh and frisky, instead of being performed when the horse has been tired. A young horse, or any horse difficult to shoe, it is especially necessary, should be sent to the forge immediately after a day's work; not sent, as is too often done, some *leisure morning*.

DRAINAGE OF THE FENS.

INTERESTING EXPERIMENT OF HALL'S
PATENT HYDRAULIC BELT, OR WATER
ELEVATOR.

On Wednesday, Sept. 9, the first public trial of the Patent Hydraulic Belt for the purposes of Fen-Drainage was made at Salter's Lode, near Downham Market.

This extremely important and interesting experiment was witnessed by a great number of professional gentlemen and persons connected with the Fens, and the indisputably successful result excited the highest satisfaction. It was evident to those who looked on this simple, but extraordinary powerful agency, accomplishing effects which have hitherto been performed at a vast expence by an elaborate and by no means perfect machinery, that a new era, about to realize the most sanguine hopes of those by whom the full importance of the object was estimated, was dawning on the prospects of Fen-drainage. From the time when the power of steam was first adapted to the draining of land, but slight advantages have been taken of its introduction beyond the mere rescue of certain districts from the capricious dominion of the winds. Cast-iron scoop-wheels have been partially substituted for the old Dutch wheel, and various other improvements have from time to time been made; but it must be acknowledged, that in the adaptation of steam-power to drainage, very many of its most advantageous effects are left undeveloped, and the greatest amount of benefit, at the least possible expence, still left unsecured. It would be needless to describe the many evils which are inevitably attendant on the system of wind-engines for the purpose of artificial drainage. Setting aside every other, the one great objection must always remain insurmountable. Their powers, however great and effective when in action, are dependent on the changeful and uncertain winds. The farmer, in the midst of his confidence and hopes, with his crops ready for the sickle, may experience sudden and complete ruin, from an unexpected fall of heavy rains, deluging his lands; while his mills, his only hope, stand with their sails unmoved by a breath of wind, and the fruits of the labour and industry of the past year perish on the ground. When most depends on the mills, they are often totally useless. At times when there is most rain there is commonly the least wind. The steam-engine is certain—its giant power untiring. It puts forth its mighty strength whenever it is required, and continues, unceasing, exhaustless, independent of all the obstacles of nature, until its task be finished. The first cost and subsequent expence of the maintenance of one powerful steam-engine is less than the expence of building, repair and attendance on a great number of windmills. Districts which formerly employed five-and-twenty mills, are now effectually drained by one steam-engine. Deeping Fen, near Spalding, containing about 25,000 acres, where there were forty-four mills for lifting the water, is now drained by two engines of sixty and eighty-horse power. March West Fen, comprising about 4,000 acres, is drained by a single engine of forty-horse power. Littleport Fen, near Ely, of 28,000 acres, was formerly imperfectly drained by seventy-five wind engines. "And often has the fen farmer in despair watched their motionless arms, and earnestly hoped a

breeze might spring up to catch their sails, whilst his fair fields gradually disappeared below the rising waters, and the district assumed the appearance of an immense lake." Two steam-engines of thirty and eighty-horse power have now secured the farmer from the irruption of the waters, and rendered him independent of the winds.

With these stupendous results before us, it may be asked, why the adoption of steam-engines is not universal? The expence of the first cost of the erection is not the only answer, but it is the one most commonly and forcibly urged. The introduction of steam must be considered merely as the commencement of improvement. Its inexhaustible powers have hitherto been but rendered subservient to the old and imperfect system of wheel-draining. Great as has been the saving of expenditure, and magnificent as have been the results achieved, it is yet evident that much remains to be done before the great work of drainage can be perfected. The moving power has been brought into operation, but it is still left to adapt to this power a machine which is in all respects efficient, and which possesses the invaluable requisites of cheapness and simplicity. Such a discovery was alone wanting to render the incalculable powers of the steam-engine, as adapted to the drainage of lands, available to their full extent, and thus to realize the fondest anticipations of those persons who have been alive to the immense national advantages which would result from a complete system of drainage.

That such a discovery has been made, the experiment of the application of Hall's Patent Hydraulic Belt, or Water Elevator, on Wednesday last, leaves no doubt on the minds of those who witnessed it. We proceed, therefore, to give our readers as full an account of this most important and interesting trial as is in our power.

Salter's Lode, where the experiment was made, is two miles from Downham Market. An engine has been erected here, and, under the superintendence and at the expense of Thos. Dyson, Esq., the intelligent and able engineer to the Bedford Level Corporation, arrangements were made for adapting the Hydraulic Belt to the engine.

At twelve o'clock a considerable number of persons, between two and three hundred, from the fens, from the metropolis, and from distant parts of the kingdom, had assembled. Among those present we noticed the following gentlemen:—

Charles O'Gorman, Esq., late Her Majesty's Consul General for Mexico; Rev. Mr. Hewlett, of *Hilgay*; Dr. Patterson of *Downham Market*; Wm. Layton, Esq., of *Woodhouse, Ely*; W. Harlock, John Hall, Thomas Archer, W. Moxley, and J. Cropley, Esq., of *Ely*; Edward Hett, G. Wales, and Thomas Dyson, (civil engineer), Esqs., of *Downham Market*; J. Mylnes, Esq., of *Hilgay*; George Press, Esq., of *Dereham*; Frederic Robinson, Esq., of *Southery*; Joseph Bebb, Thomas Hall, and—Bender, Esqs., of *London*; William Thorold, Esq., (civil engineer), of *Norwich*; Messrs. Little, of *Littleport*; Fullerton and Reynolds of *Lynn*; Boyce and Pryor, of *Hilgay*; Brooker, Chapman, Dixon, Hubbard, Johnson, Kemp, Mumford, Palmer, Pocock, Smith, True, B. Ward,—Ward, jun., and Weston, of *Downham Market*; Martin, of *Wainfleet*; Thompson, of *Boston*; Green and Atkinson, of *Wakefield*; Hancock, of *London*; Porter, of *Corentry*; Pratt, of *March*; Compton and Kendle, of *Fordham*; Giblin, of *Swaffham, (Cambs.)*; &c., &c.

Letters were received from several distinguished

individuals, regretting their absence, occasioned by other pressing engagements at different public meetings held that day. The greatest interest in the proceedings was displayed by those present, and the engine was no sooner set in motion than the expressions of wonder and admiration at the extraordinary effects of so apparently simple a machine, were loud and general.

The belt is composed of a woollen material, passing over two cylinders of wood at a certain distance from each other. Any number of belts may be employed, according to the body of water to be raised. By the mere velocity of the belt, a sufficient attraction is produced to raise the water and throw it over the top cylinder. For the purpose of the experiment, the engine was made to employ about three horse power, and with this extent of force more than 800 gallons of water were raised per minute, at a lift of about twelve feet. The superiority of the belt over the ordinary mill was sufficiently attested by the comparison the spectators were enabled to make by the keeper of a wind-engine near setting it in motion. This mill was of twenty-five horse power, and at the time of the commencement of its operations had the advantage of the water running off, by the belt raising the water to its level; yet the greatest lift did not exceed two feet, nevertheless it raised no more water than the belt worked, as before mentioned by the engine, at three horse power. In the opinion of the engineer, the additional outlay of but £75 would serve to raise 2,500 gallons of water per minute, instead of 800 gallons.

The triumphant success which attended this experiment of the Hydraulic Belt, most gratifying as it must have been to the ingenious and enterprising inventor, proved scarcely less so to those among the numerous persons assembled to witness it who were capable of estimating the extent of utility to which it might be made serviceable, and of appreciating the advantageous improvements it is capable of effecting in the great work of fen drainage. That a degree of opposition may be offered to the introduction of this beautiful invention in the fens is what may be expected, from its militating against the class-interests at present connected with the old system; but this opposition will do little against the weight of the influence of the experience of practical benefit, or against the commendation of men of great scientific eminence. The Hydraulic Belt has received the sanction of the most celebrated engineers of the present day. The name of Mr. Dyson alone is sufficient to warrant its entire success; and the confidence which this gentleman expresses in the certainty attending its adoption, inspires us with the hope that the time for a great and most renovating revolution in the drainage of the fen is approaching.

At the close of the experiment a large party of gentlemen interested in the Fen Drainage, and the friends of Mr. Hall, dined together at the Crown Inn, at Downham Market, where an excellent dinner was provided, and the festivities of the evening appropriately concluded a day which we cannot but think pregnant with immense advantages to the nation at large, as well as to those immediately concerned.

The following additional particulars, from a highly intelligent correspondent, we have great pleasure in laying before our readers:—

The great level of the Fens, in consequence of the various rivers that intersect it, is divided into districts, each having its own method of draining.

The principal mode hitherto adopted is the wind-mill, which drives a water-wheel; the diameter of these wheels is governed by the head they have to throw against. It mostly happens that two mills are required, one not being sufficient to throw the water high enough; the heights of the head of water are various, occasioned by the difference in the level of the land, and also the point of discharge. The mode of draining by wind, is admitted on all hands to be the cheapest, but it is very uncertain; because it most frequently happens that, in times of flood, there is little or no wind. The proprietors in Downham Fen last season knew this to their sorrow to be a fact; for the mills were working a fortnight, and instead of the water diminishing, it gained upon the mills nearly two inches. In consequence of this uncertain mode of drainage, the land was never cultivated in the manner in which it should have been; for the deeper you can take off the water in the winter season the better—it being not only better for the crops, but requiring less labour in draining; for the deeper the drains are, the less water is required to be discharged from the land itself. This can be accounted for by the evaporation and soakage that takes place in that particular soil; it makes the land more firm, and also enables the agriculturist to improve the soil by claying, which within these last few years has become very general. The depth of the clay varies very much; in some places it is close to the surface, in others, six feet and upwards. The state of the Fens is very much improved since the opening of the Eau Brink Cut, by lowering the head of water in the rivers, thereby producing greater facility of discharge. The rage for improvement that has taken place in this country for several years past, has not extended in proportion in the fen country, where it is so much required, as in other parts; but latterly the agriculturists have bestowed themselves a little more, and they have been substituting steam power for wind, which has been found to answer perfectly. But in some districts, the fen gentlemen would not be driven from their old plan, but will, there is no doubt, in time, when they find their neighbours in other districts reaping golden harvests at the time their crops have been drowned all the winter. Some districts are situated much better for drainage than others; some only require the water to be lifted three or four feet, whilst others require it to be lifted ten to fourteen feet, thereby requiring more or less power. The head in Downham Fen is at the most twelve feet; a great height to throw, which makes it more expensive in a small fen, it only containing about 1600 acres, and a portion of it bad land. The Hydraulic Belt is more fitted for a district where the head is great. It has also another advantage; it can take the water out to any depth. The trial that was made on the 9th inst., was to shew what advantage was gained between the power and effect, and by the engineers present it was admitted to be manifest; for the engine was only working to about three-horse power, and her whole power is twelve horses. Some malicious individuals, who would be out of office if this engine were to be adopted, set off the wind engine, to shew how *she* could throw out the water. But it must be recollected, that the wind engine is a twenty-five horse power. It was working with no head against her, whilst the Belts were throwing the water ten feet directly upon the tail of the engine; therefore she was almost impelled by the water from the

Belt. It is intended to put on sufficient belts, so that in the wettest season the Fen may be drained. It is calculated that the Belt will discharge about 2,500 gallons per minute, at flood height, and then about eight-horse power will be employed, and four-horse power be left to spare. In order to throw 2,000 gallons per minute, flood height, would require a steam engine with a wheel from twelve to fifteen-horse power. The only doubt entertained with respect to the Belts, is the durability of them; this will be ascertained by working one season. It is said they will last two years; if so they will answer,—but this is to be tried. For single farms, this plan of drainage will be singularly applicable, from the saving in power, and in the construction of the buildings. It is a very difficult thing to persuade the Fen gentlemen to adopt any new contrivance, or to drive them from their old plans; nothing but time will convince them.—*Cambridge Advertiser*.

REPORT ON THE TURNIP CROP ON STRONG LAND;

INCLUDING THE QUALITY OF THE LAND,
THE QUANTITY AND QUALITY OF MA-
NURE APPLIED, AND THE MODE OF
CONSUMING THE TURNIPS.

BY MR. WILLIAM LINTON.

(From the Transactions of the Yorkshire Agricultural Society.)

The cultivation of turnips upon strong land is so difficult, and depends so much upon the seasons, that it is impossible for any one to adopt any mode from which he is not obliged in some seasons to deviate. I here give the general system I adopt, and that which answers my purpose the best.

The land which is the subject of this Report, is very strong and stony, with a good depth of soil, of a fair quality, with a clay bottom, and is under-drained down each furrow.

The land intended to be sown with turnips (which is wheat or oat stubble having been sown after seeds) is ploughed the first time in November, with a very strong plough drawn by four horses, to the depth of 8 and 9 inches. In the spring following, as early as the weather will permit, it is ploughed again; then harrowed down with a pair of iron harrows drawn by 3 horses abreast. After this is done the land is principally tilled and cleaned by an implement which I call a cultivator. It is drawn by 4 horses abreast; both machine and horses are managed by 1 boy, which can effectually break up from 6 to 8 acres per day, and is equal to a ploughing, and in many cases much better. The plough afterwards is seldom used except to keep the lands to their usual position and height. By this means, and the use of a heavy roller to break the clods, I get the land intended for Swedish turnips ready for sowing by the beginning of May, but allow it to lay to rest and gather moisture until the last week in that month. If sown sooner they are subject to mildew, never keep so well, and are not so good in quality.

The plan adopted in sowing is to make ridges so far apart that a cart can span two of them. They are made by a common plough, with a loose mould board fixed to the left side. By this simple

contrivance, we can make a ridge at once, without having to go twice in one place, which would be the case without it; the land being so strong and stony the common double mould board plough cannot be used. I then spread in each row, as equally as possible, about 14 loads of good fold-yard manure to the acre. Then divide the ridges with the plough, the same as in making them; thus covering up the manure, which is done very lightly. After which 3 pounds of seed to the acre is drilled, attaching a light roller to the drill, long enough to pass over two ridges; the one it levels and prepares for the drill, the other covers up the seed after the drill. In droughty weather the above processes are carried on as quickly as possible after each other, so that the moisture is not lost.

The fly being so very destructive upon strong land, I find it necessary to drill not less than three pounds of seed to the acre. Thick sowing encourages the plants when young to grow much more rapidly than if sown thin; and, by drilling with the seed a compost noticed hereafter, the fly has never yet disappointed me of obtaining a good crop. In hoeing I do not attempt singling the plants the first time over, but leave 2 or 3 together, 10 inches apart; afterwards singling them with the hoe and hand, using the scruffler when necessary, just as the weeds may spring up; and if the land becomes too hard through wet and then dry weather following, so that the scruffler cannot work, the plough is used first, drawn by one horse.

The land intended for white turnips is cleaned and cultivated exactly in the same way as that for Swedish, and sown about a month after: but only 12 loads of manure is spread upon the acre; and if sown level, not in ridges, the same quantity of manure is spread upon the land; is beat small with forks, and immediately ploughed in; then harrowed with a pair of light harrows with short teeth, or turned wrong end first, so that they may not drag the manure to the surface. The drill follows, sowing 3 rows at once, 18 inches asunder, 2½ pounds of seed per acre, and as much compost as the drill will lay on. I follow the same plan in hoeing the white turnips as I do the Swedish. The purple-topped Swedish turnips and the white Norfolk are the kinds I generally sow.

Description and Quality of the Manure.—Fold-yard manure is the kind I use which is carted out in February and March, and laid, about 3 feet thick, in a situation most convenient for where it is intended: 6 weeks after, it is turned over, and remains in that state until wanted. The turnips are consumed by my cattle, being given in the fold-yard and houses: the manure is of good quality, as it gets all the dung from the cattle well littered down. After the turnips intended for the cattle are used, I give them from 3 to 4 pounds of linseed-cake per day; which is a further improvement to the manure.

The compost referred to as being drilled along with the seed consists of two-thirds of the best manure (particularly that from the pigs when feeding, which is kept until very rotten), one-third ashes, and one-tenth pigeon-manure;* and, if too wet to pass through the drill, a sufficient quantity of quick lime is thrown amongst it to

* This compost contains the strongest of all animal manures, without doubt accelerates the growth of the plant, but can have no effect whatever in preventing the ravages of the fly.—W. MITES.

cause it to separate. Before the drills were made sufficiently wide I found it necessary to pass it through a wide riddle. A cart-load or two of this compost is drilled upon an acre with the seed, which greatly encourages the plants whilst young, before they have sufficient root to lay hold of anything else, and is a great support when the fly is upon them.

I have used 3 or 4 chaldrons of lime to the acre, in lieu of the manure, but have found most benefit arise from the manure in the succeeding crop of clover-seeds.

The mode of consuming the turnips.—It has been my object for several years to pull my Swedish turnips in November, cutting off the roots and tops, giving the latter to the cattle and ewes; then carting the bottoms together, laying them in a heap or heaps near the fold-yard, about three feet thick, covering them with loose straw about 4 inches thick, so as to admit of wet, and in part keep out the frost, as well as the sun and drying winds in the spring. In this way I regularly preserve my Swedish turnips, and can have them in as good condition in May as I could wish for—much more so than in any other way I ever tried or heard of. After the tops are all consumed I then begin to use my white turnips; after them the Swedish, which are given to my cows, fat beasts, and ewes when lambing. If I pull up a quantity of white turnips in November I consume the tops immediately, keeping the bottoms in the shade; but consider two months long enough to pull them before they are wanted. In February I pull off what remains upon my strong land, and preserve them the same as the Swedish, in a sward-field, for my sheep until later in the spring. By this they are prevented growing, and are much better food than those which are allowed to stand until April. I also get my sheep off the light land on which I eat the turnips much sooner, and am not thrown back in getting the land sown.

General Remarks.—I always consider it bad policy to grow turnips upon strong land with an idea of eating them upon it; or to pull and cart them off in wet weather: and consuming them upon good sward with cattle not only robs the fold-yard manure in quality, but also in quantity, and does no good to the sward the following summer. Since I began to give my cattle their turnips in the fold-yard and houses, my sward will graze one-third more. Where the sward is light land, dry, and of a tough nature, treading will be beneficial to it; but we are speaking of strong land.

Much has been said respecting the best way of preserving Swedish turnips; and it appears that the plan of planting or paving them upon sward is one much practised, but does not give satisfaction, which I am not surprised at. I object to it for the following reasons:—first, the tops are destroyed, which are valuable if cut off in November. I consider them worth double the expense of pulling, which costs from 7s. to 9s. per acre. Secondly, they are exposed to all the weather during winter, and when wanted are often covered up with snow, and have all to be cleansed as when growing in the field, as well as to be given to the cattle in a frozen state, which is bad management. Thirdly, the trouble and expense in paving them. By the plan adopted in this report the tops are turned to an account, the bottoms are preserved in as good condition as possible, and are always ready for use without further trouble or cost. If they are put into a house, or laid too thick for a length of time, they heat, and will become mouldy, dry, and soft.

They must be kept cool and moist. Care must be taken that they do not get much frozen, after they are cut off, before carting away out of the field, and that the bulb is not cut into, either at the top or bottom.

Manure is generally considered best when rotten; in this opinion I do not agree: if it be short enough so that the plough can cover it up with mould, it will answer as well for turnips upon strong land, if in ridges, as if it were ever so much reduced; and much better for the succeeding crop of corn. I have used bones, but did not find them to answer equally well in proportion with the cost on my strong land. The compost drilled, as described, is an excellent substitute, and can be procured at one-tenth of the cost; and, what is of the first consequence to a farmer, he has it within himself, saving both the cost and the cartage of bones, generally bought at a distance.

WILLIAM HINTON.

Sheriff: Hutton, near York.

The Cultivator.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—I observe in your last number, an enquiry, by a "Lancashire Subscriber," as to the best mode of marking sacks. I never found an effectual recipe; my neighbours and brother corn chandlers are always complaining at the continual loss of sacks, marked ever so well, my firm belief is, that mark them with whatever consistence you may, that the solution which stolen sacks are steeped in, to destroy the marks before they are sent and sold to the paper makers, will frustrate the best preparations for marking sacks.

ON THE USE OF SALT AS A MANURE, BY H. D.—The method that I have used salt for manure, is by spreading it in the farm yards, and in the dung-mixens, it is there well mixed, and goes out regularly with the dung on the ground. I have found great benefit in the crops by this simple and convenient mode of applying it. It is also a great benefit in the manure retaining its moisture, the same method I use *Sea Weed*.

A SUSSEX AGRICULTURIST.

REMARKABLE SCOTCH THISTLE.—There is at present growing in the garden of Miss Sharp, Crieff, a Scotch thistle, measuring eight feet six inches in height, and twenty-four feet in circumference. It grows under a tree, and it was lately observed to have grown at the rate of several inches a day.

AGRICULTURAL MEETINGS.

The march of improvement in every department of agriculture is no where more clearly demonstrated than in the proceedings at and general character of our agricultural meetings now become too numerous even to be hastily read without sacrificing a larger portion of time than ordinary avocations will permit. To attempt even an abridged account of them in a Journal, where business matters have a paramount claim, would be vain; in very many cases therefore, we must be content, as we trust our readers will, with a cursory glance at them, and occasional extracts of those parts of the proceedings which contain the most useful information. We cannot, however, refrain from giving at length a report of the proceedings of the "Northamptonshire Farming and Grazing Society," the exhibition of cattle at which meeting takes place on Earl Spencer's farm at Chapel Brampton, not only because this Society enjoys the special advantage of the support of Earl Spencer, who, as was well observed by the Chairman at the dinner, is now "generally regarded throughout the country as the *great patron of British agriculture*," but also because it is the 21st anniversary of the presidency over the Society of that veteran agriculturist, Mr. Hillyard. We trust he may long be spared to fill an office, the duties of which we are convinced he is most anxious to perform in the manner best calculated to promote the interests of the Society. The Society has obtained a signal advantage in the addition to its list of members, of a nobleman whose name commands the respect of the British farmer, in consequence of the benefits conferred on our national agriculture by his ancestor, and who we know is fully prepared to prove himself a worthy descendant of the Duke of Bedford. His Grace the Duke of Bedford was present at the meeting, and expressed himself proud of being admitted a member of the Society, and offered a premium, the disposal of which he placed in the hands of Earl Spencer. Mr. Benzy showed that he fully entered into the spirit of Earl Spencer's donation of a prize of fifty sovereigns for a short-horned bull, to be used in the county, by having supplied one which carried off the prize. We have now before us reports of several Agricultural meetings. We shall first advert to the meeting of the "Netherby Agricultural Society." Most of our readers are aware that this meeting was established by Sir James Graham for the tenantry on his own estates, and although many strangers attend the meeting, still the competition for prizes is confined to the tenantry and cottagers upon the estate. The proceedings at this meeting are always distinguished by that kindness of feeling, which it is so delightful to witness as existing between landlord and tenant, when based upon a sound principle,—not that servile attachment which is extracted by fear, from a knowledge of the power of the landlord over the tenant, and of his disposition to exercise that power, but that respect and attachment which will always be kindled in the bosom of the British tenant farmer, when he is treated as an independent man, as one who being prepared to employ his talents and his capital in the cultivation of the soil, confers as

great an obligation upon the owner of it in so doing, as does the landlord in contracting with him for the occupation of his land. Sir James Graham is himself a practical farmer, and, is therefore, better fitted to appreciate the real position of his tenantry. As business of any kind is always more satisfactorily arranged with men of business habits, so will the tenantry of a man practically acquainted with farming, except under peculiar circumstances, experience better treatment and greater consideration than at the hands of one who is perfectly unacquainted with the practical operations of husbandry. In his address at this anniversary meeting, Sir J. Graham generally communicates some useful practical information, the result of his own experience and observation. Last year his remarks upon draining would be found of value, not only to his own tenantry, but to all others engaged in that most important operation. His remarks made at the late meeting upon the cattle best adapted to that locality are well deserving of attention in other parts of the country:—

"I cannot, in passing, avoid expressing to the gentlemen present, the great pleasure I feel at witnessing the visible improvement in the Galloway stock exhibited in this year's show. I have often expressed my conviction that, except upon the best land and in the finest situations, Galloway stock will, in the long run, be found to be best suited to this estate and this climate. I was once very much attached to short-horns, and had a large number of them; but, on experiment, I am persuaded that, although in my own hands they might be profitable and useful, for the great body of tenantry and occupiers in this neighbourhood Galloway stock is preferable. I therefore put down my short-horns and bestowed much trouble in obtaining the best and purest Galloway blood, which I am happy to find is now generally diffused throughout this neighbourhood. I particularly rejoice in observing the progressive improvement in this breed on the estate, and I think I never saw so many good Galloways on any former occasion. I am persuaded they will be found to be a profitable stock. I fed four Galloway bullocks last year, which I sold before they reached four years old, for a sum considerably above a hundred pounds. One of them fetched 30*l*. I have also had tempting offers for Galloway cows within the last three or four months. I think the conviction is spreading that in a wet climate, and exposed and ungenial situations, they will prove the most profitable stock. Recollect, I do not wish to discourage the breed of short-horns on the best land; on the contrary I think that, under those circumstances, they may be made profitable, but I repeat that on higher land, speaking generally, Galloway stock will be found to be best suited to this climate and neighbourhood."

Mr. Teather when returning thanks on his health being drank, observed—

"When he first knew the Netherby estate the now fertile lands on the banks of the Esk and the Lyne were little better than a waste, with here and there huts composed of clay walls and covered with straw. He had seen the waste converted into excellent land, and, as if by magic, the mud huts were supplanted by good stone buildings, not only for the occupiers, but the cattle, and every thing requisite for the cultivation of the farms. Some of the buildings were, indeed, more like mansions than farm houses. He had also witnessed the greatest improvements from drainage. At the time when he first became acquainted with the estate there was scarcely an under-drain upon it, and the land was so saturated with water that it was impossible for the cultivator to get the seed into the ground at the proper season, and, consequently, the harvest was unnecessarily late. Since it had been

drained the seed was got in early in the spring, and the harvest was now, generally speaking, a month earlier than it used to be." (*Hear, hear.*)

Sir J. Graham in proposing the health of his agent, Mr. Yule, passed a well merited eulogium on that gentleman's conduct. Mr. Yule returned thanks, and in the course of his remarks said—

"It was of the first importance to obtain good seed for the incoming crop, and he therefore proposed that there should be a show of seed at Longtown, and that the seed should be exhibited in the bulk." (*Applause.*)

The proposition met with general assent, and it was understood that the necessary arrangements would be made for carrying it into effect.

Thus another step is taken to render this Society still more useful.

The next meeting which comes under our notice, is that of the "Hexham Agricultural Society," over which J. C. Jobling, Esq., of Newton Hall, presided; and we regret that our limits will not enable us to give a full report of the proceedings. This Society was founded by Mr. Grey, of Dilston, whose zeal for the cause of agriculture, is well known and as was well observed by the chairman—

"Whose great practical knowledge is equalled only by the urbanity and ability with which he is ever ready to impart that knowledge."

The chairman gave the following detailed statement of his experiments in draining, and sub-soiling:—

"He first commenced with seven acres of land, which would be dear to rent at 5s. the acre, and which was a strong yellow clay; it was fallow in 1836, and in 1837 produced 72 bolls of oats at 5s. 6d., which amounted to 19l. 16s.; not being satisfied the second year with the condition of the land, he put in 249 roods of draining, which cost, including stone, which was principally in the field, 10l. 12s. 10d., but in consequence of the low situation of the field he was obliged to make a large drain to take away the water, which with the service drains, cost 23l. 5s. 10d., making a total of 38l. 16s. 8d.; last year the seven acres produced 88 bolls of wheat under the same treatment, which at 14s. 6d. the boll, came to 63l. 16s., leaving, after deducting the 38l. 16s. 8d. outlay, charging everything, a balance in favour of last year's crop over that of 1837. In 1836 an eight acre field, he would observe, only produced 66 bolls of wheat, since which it had been drained at a cost of 34l. 1s., and last year it produced 88 bolls; it was also a very late field, and last year was the first that was ripe, and the crop was sold at 17s. 6d. the boll, producing 18l. 15s. over the former crop, or more than one half of the cost of draining, &c. The last field he would mention was one of clay, with moist soil, on which it occurred to him that he might have a crop of turnips, and in which he was very much opposed. The cost of ploughing and draining this field was 32l. 6d. 8d., and the additional expenditure necessary for a turnip crop, including seed, extra manure, tithe, &c., was 10l. 0s. 10d., making 42l. 7s. 6d., and the produce of the crop was sold at 6l. per acre, or 30l. leaving a balance of 12l. 7s. 6d. against the field. This year the field was in mashin, and its value would not leave the field in more debt than 3l. 13s. 4d.

The following items will give a clear idea of Mr. Jobling's success in sub-soiling and draining. They have reference to one field only which is of very strong clay with little or no soil.

6d. per boll	63	16	9

Difference in favour of 1839, after sub-soiling, &c. 44 0 0

The following observations of Mr. Grey are valuable, more especially as the use of nitrate of soda as manure is extending itself daily:—

"With respect to improving the soil, he had tried the nitrate of soda upon a piece of grass land, and he found that on the parts to which he had applied the nitrate of soda the grass was outgrowing that on the other soil at a rapid pace. In one hundred and twelve square yards, without the application of the nitrate, he had nine stone seven pounds weight of hay, whilst in the same space, with the application, he had fourteen stone four pounds, which gave about a ton and a half more to the acre than usual, and at an outlay of only twenty-two shillings. On the corn land he had been more successful with the maslin than he had been with the barley; he did not think, however, that the application would be so successful in wheat as it had proved in grass. He had also applied gypsum at the rate of twelve bushels to an acre, but it was not so effective as the nitrate of soda. He then tried gypsum and the nitrate of soda combined, but that was not so productive as the nitrate of soda alone, and that convinced him that they could not attend too closely to the suggestion thrown out by Mr. Monck, of paying particular attention to the application of scientific mixtures to the soil." (*Applause.*)

Another important agricultural meeting, that of the "East Suffolk Agricultural Association," was held at Wickham market on Thursday last. Earl Stradbroke is president of this Society, but was unfortunately prevented from attending by indisposition, and the chair was taken by Lord Huntingfield. The "Suffolk Chronicle" says:—

"The shew in the field, though containing many good specimens of beasts and sheep, was not, we think, so great in this department of stock as we have seen it. Its superiority consisted in the horse stock, of which there never was a larger or better display under any circumstances made in the County of Suffolk. This character may indeed be given, whether as respects animals of the draft or riding kind. We particularize the following, as being highly approved animals, and as exhibiting those qualifications which have made the breed of Suffolk horses renowned through the three kingdoms. Among the entire animals for riding purposes we noticed Knowsley, a 5 year old, belonging to Mr. Freeman, Heulham, between 15 and 16 hands high; Young Watton, belonging to Mr. Easter, Benhall, 3 years old, a fine strong colt, of very symmetrical shape, and handsome head; a 4 year old horse, belonging to Mr. Morgan, Bramford; and an iron-grey colt by Whisker, 2 years old, belonging to Captain Broke, Ufford. Among the Cart Stallions—a fine animal belonging to Mr. John Gobbett, Iken Hall, 3 years old, named Captain, a Suffolk sorrel mixed with white; a fine stallion called Briton, 3 years old, bred by Mr. Plant, Farnham; Blake, a stallion, 3 years old, bred by Captain Broke, Ufford; Briton, 3 years old, belonging to Mr. Rist, Foxhall; Boxer, 5

years old, belonging to Mr. Catlin, Chillesford (shewn last year); a fine animal belonging to Mr. T. Crisp, Gedgrave, 5 years old; Boxer, 5 years old, belonging to Mr. Worledge, Creeting; Briton, 7 years old, belonging to Mr. Keer, Reydon; Boxer, 5 years old, belonging to Mr. R. Easter, Benhall; Captain, 5 years old, belonging to Mr. T. Crisp, Gedgrave Hall. The mares and foals were also very good, as also the geldings. The entire horses, however, were the pride of the field. We noticed also a Suffolk cart filly, bred by Mr. Garrard, Laxfield, of very superior character, as also was a similar animal bred by Mr. T. N. Catlin. A cart foal bred by Mr. James Wells, Dennington, was also much admired. Mr. Kersey, Framsdon Hall, shewed several excellent Suffolk horses. Among the bullocks we noticed some very fine animals. A short-horn by Lord Huntingfield, 15 months old; a 2 year old short-horn, by Mr. T. Crisp, Gedgrave; a 3 year old bull, by Mr. Worledge, Creeting; two Suffolk bulls, 2 years old, belonging to Mr. Crisp, Chillesford; Lord Henniker also showed a good bull. The Suffolk cows shewn by Mr. James Reid, Laxfield, were much admired by the farmers on the ground. There were 25 Suffolk cows shewn, all of superior character, including seven competitors for Lord Henniker's cup in this description of animal. Mr. Blofield, of Monewden; Mr. Turner, Kettleburgh; and J. Moseley, Esq., also shewed good cows of the same kind. A very fine hog was also exhibited by Mr. Hanbury, Hacheston. Among the sheep were several very fine down tups, shewn by Mr. T. Crisp; some fine Leicester shearing ewes, exhibited by Mr. Nathan Crisp."

The chairman expressed in glowing terms the pride he felt at the high position in which the County of Suffolk stood, both as regards its cattle and farming, and wound up his observations by the following pithy remark:—

"But such was the general good character of the county, that it was considered superior, not only in the breed of cattle, but also in general farming. The Suffolk farmers were considered the best and neatest in England. Yes, this was the character universally assigned to them."

We do not know how some other counties in England may receive these remarks, challenges having lately been very rife, we should like to see a challenge between the County of Suffolk and some other well cultivated county.

Lord Henniker in returning thanks, as one of the members of the county, said:—

"He would just refer to that portion of agriculture which might be termed the chemical part, and lead them back to the observations made at the Cambridge meeting by Professor Buckland on this point. What he particularly wished to observe, and to which the observations of the Professor were directed among other matters treating on the same subject was, that there existed an office in London where soils were analyzed, and through which analysis the agriculturist could be made acquainted with the certain qualifications of the soil which he tilled." (*Hear, hear.*)

In reference to this remark of his lordship we are enabled to state, that there is a chemical laboratory attached to the Polytechnic Institution, being the back part of the premises occupied by the Royal Agricultural Society, in Cavendish-square, where any soil will be analyzed at a cost of thirty shillings for each analysis. So far the object desired by his lordship may readily be attained.

We were much gratified by the following commendation of Farmer's Club, pronounced by R. N. Shawe, Esq.:—

"These societies had also been instrumental in originating those useful institutions now springing up called Farmer's Clubs. (*Hear, hear.*) They were of great

benefit to the farmer, inasmuch as no man required to be brought more closely in connection with his fellow men, and yet the occupation of the farmer, in a manner isolating him from his friends, rendered communication difficult. Farmer's Clubs, however, remedied this evil, and were the means not only of bringing men together, but also of assisting materially the interests of that employments in which their members engaged." (*Hear, hear.*)

It is highly satisfactory to see that the attention of this association is not confined to the breeding of cattle only, encouragement to improve the cultivation of the soil is held out, as will be seen by the following awards:—

"To the tenant (a member of this association) who shall have spade-drained from the Annual Meeting, in September, 1839, to the 1st August, 1840, the greatest number of rods (not less than 4,000), to be adjudged at the discretion of the Committee, a premium of 4*l.* This was awarded to Mr. Robert Foulsham, Darsham, for having drained on his farm, containing 235 acres—47 acres, with 7,243 rods of five and a half yards each, and filling the same with whins, &c., in one year.

"To the member of this association who has used the subsoil plough to the greatest extent in proportion to his occupation of arable land, within the year ending 1st August, 1840, not less than ten acres to have been so ploughed—at the discretion of the Committee a premium of 4*l.* This premium was awarded to Mr. Lewis O. Cottingham, Reydon, by Southwold, for having subsoil ploughed 89*ac.* 1*in.* 17*ro.* on his farm of 412*ac.* 1*in.* 8*ro.* between Aug. 1, 1839, and Aug. 1, 1840."

—*Mark Lane Express.*

NITRATE OF SODA.

SIR,—In answer to O. D., Cheshire, I would, in the first place, say that nitrate of soda will not exhaust the soil, be it siliceous, a stiff loam, or any other soil. I do not say that the soil is of no consequence in the application of nitre, and that the benefit will be the same on all soils. No rule can possibly be laid down, owing to the diversity of earths. The farmer must find out by experience where the dressing will do most good, and whether the crop will be benefitted enough to pay for the outlay.

All nitre, whether nitrate of soda, potash, or lime, contains a great quantity of oxygen, which goes to the nourishment of the plant and increases its productiveness. Nitre cannot be serviceable only to one crop; a minor part may enter into and unite with the soil, but that is not the fertilizing part; the conclusion we are to arrive at, then, is that repeated applications will benefit succeeding crops. One more word respecting soils: a farmer ought, in the present advanced state of agriculture, to be able to analyze the different soils that he has to cultivate, and then he would be able to judge what sort of manure or what top-dressing would suit best—all we want is pabulum for the plant.

SENEX.

Ipswich, Sept. 10th.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—In the *Mark Lane Express* of the 21th ult., "An Irishman" wishes to be informed, what is in and in breeding? The question is a very simple one, and put with seeming sincerity.

I consider judicious in and in breeding, to be the first establishing a breed of animals with as few faults as possible; then from that time excluding all strange blood, and with a watchful eye, and on scientific principles, keeping for breeders such only, males and females, as have arrived nearest to perfection; caring not

a straw in what degree of relationship they may chance to be to each other, or as is so much better expressed by Sir John Sinclair, who says, "When a race of animals have possessed, in a great degree, through several generations, the properties which it is our object to obtain, their progeny are said to be well-bred, and their stock may be relied on; and it cannot be doubted that any breed may be improved in the same manner."

And should "Irishman" desire an illustration, I beg to refer him to that eminent sheep-breeder, Mr. V. Barford, of Foscoate, near Towcester, Northamptonshire, who has strictly in-and-in-bred, entirely from his own flock, sire and dam, from the nearest affinities, and without an interchange of male or female from any other flock for the last thirty years; and now his sheep are fine in wool, with aptitude to fatten; superior mutton and small in the bone, handsome in symmetry and hardy in constitution.

I am, Sir, yours, &c.,

A LOVER OF IMPROVEMENT.

TO THE EDITOR OF THE FARMER'S MAGAZINE.

SIR,—Whatever tends to improvement has always been acknowledged worthy of record, and as this principle has hitherto prevailed in general adoption in the arts, mechanics, and other branches of national economy, allow me to call your attention to the merits of two individuals whose occupations are of a more retired, but not a whit the less important nature; in short, they are of that useful class which modern phraseology denominates agriculturists, or in plain old English language, farmers.

I know their modesty will shrink from this statement, but I hold, Sir, that he who does well deserves well, and upon this principle I will not apologize for troubling you with a statement, if not important, at least interesting.

The first of these is a Mr. Thomas Pickford, who a few years back took a farm at Cheadle Heath, in the parish of and near the village of Cheadle. The farm was, when he entered upon it, in a most miserable plight; the land almost exhausted, the fences down, and in short anything but tempting. Although Mr. P. was a young man just married, and entering upon life, this dreary prospect nothing daunted him: on the contrary, he set about his work with an earnest determination, and improvement followed his steps. He was to be seen late and early hard at work, for he is one of those who say to their labourers come, and not go. His carts were to be observed daily wending their way to the farm laden with manure from the neighbouring town of Stockport, himself invariably one of the drivers, having been most active in the labour of loading; and the consequence appears on looking at his fields, the dreary appearance of brown, and sour looking vegetation has vanished, and given way to the smiling verdure of the most approved cultivation. When he first commenced operations his barn and hay lofts were not half filled with crops, and now they are crammed with produce, and around them stand as sentinels goodly stacks of grain and fodder, which present the picture of plenty (a prototype of the farmer's own contented face) to all who view them. Pomona presides over his orchard, and Ceres over his crops, whilst his dairy overflows with lacteous beverage and unctuous butter. His fences are barriers well maintained, and smiling peace with bounteous plenty meet the spectator on every hand. This, Sir, has all been done in a very few years, and the means are simple; he is a practical farmer, he is a worker, his wife is

a worker, and all his servants, male and female, are and must also be workers too. Luxury gives way to plenty, and dainty bits to nourishing food of a substantial nature. He sees that his work is done, and himself works as hard as any man he has; his wife is a worker as well; he is training up his children to industrious habits, and he pays his rent, his tithes, his rates and debts with cheerfulness; thanks God for his mercies, goes to bed early and rises early, and contented follows his employ briskly; never interferes with politics or religious squabbles, nor murmurs against his landlord, and he has met and will meet with his reward. May he continue to enjoy that prosperity and happiness he so richly merits!

Now, Sir, for my next instance of what may be done by industry and perseverance. My hero is Mr. Francis Taylor, whose first occupation was the humble driver of a waggon for the Northern Mill. Frank was as frank as his name, he followed his team and whistled away care, although carefully bearing in mind one object, which was to raise himself in the world, and he has been successful. His next employment was that of watchman over the print works and bleach crofts of Thos. Marsland, Esq., M.P.; his economy soon enabled the watchman to show the fruits of his watchfulness by taking a small farm under Mr. Marsland, and an additional one some time after from a Mr. Campbell, at Cheadle, two miles from the other, and he still holds them both, the condition of which is beautiful. His industry is proverbial: he constantly walks from one to the other several times a day, or is working at one or the other of them. He has them both personally to manage, and, Sir, he does manage them. There is a sort of friendly contest between him and his friend Pickford, which produces the best crops, and presents the best appearance on their land; still they envy not each other's prosperity; consult each other and advise on what is best, and are ready to help each other in time of need.

Such tenants as these are a credit to any landlord, and I trust they will ever experience that assistance from their's which they so well deserve. Their motto seems to be "waste not want not," and they act as though that school-boy copy, "idleness is the root of all evil," were constantly in mind.

I hope you will pardon the length of this letter. I would plead in excuse that you have a correspondent in a neighbouring township, who often explains his cultivation in your useful journal, and he is a good farmer—a gentleman farmer worth his thousands a year. Such men as I write of cannot be expected to try the various plans which he adopts, for lack of means; they have rent to pay, he has none; they cannot run to the Bank to cover their land for a crop—their only bank is the land they cultivate, and the bank of industry; and permit me to say they are as worthy the annals of fame as any gentleman farming his own land, albeit the improvements he has made may have cost him thousands; for, he may not have his rent raised, or be forced to quit on a slight disagreement with the landlord—a consummation I hope my two friends, the farmers I have spoken of, may never have to complain of. They would be a credit to any estate in England.

I am, Sir, yours obediently,

A FRIEND TO IMPROVEMENT.

P.S.—I have another or two instances of good management to record, which, if this meets with your approval, shall be duly forwarded.

ON RECLAIMING BOG.

SIR,—Your correspondent, "A Lancashire Agriculturist," recommends a "Farmer north of the Tweed" to visit Chat Moss and inspect the reclaimed farms of Mr. Baines, M.P., and others there. I have visited them and join in the recommendation; for, most certainly, they are strong illustrations of what may be done with the wildest and most sterile bogs. Chat Moss was such; and, indeed, a portion of it remains so still. It may be acceptable to "A Farmer north of the Tweed" to have a general outline of the method pursued in draining this moss, but prior to describing it, it would be well to state that Chat Moss is a deep bog, from 10 to 30 feet deep. There is a wide difference, both in the chemical and mechanical structure of deep "red bog" (as we term such as Chat Moss here,) and shallow "black bog;" and the method pursued, and expense of draining these two descriptions of bog, vary very much.

The first operation in draining the farm held by Mr. Baines, and that held by Messrs. Evans, was to cut open drains: this was done gradually (a foot to 18 inches deep at a time) it being found when the whole depth of the drain was made at one operation the pressure of the water caused it to collapse, and, consequently they had to be remade. The usual size of the open drains is 4 feet 6 inches deep, 4 feet 6 inches wide at top, and 18 inches wide at bottom, they are made parallel to each other; I do not recollect at what distance, but I think about 20 perches.

Cross drains are made at intervals. When these drains have drawn off so much water as to cause the moss to consolidate in some degree (in which consolidation the surface sinks considerably) they are again gone over and made of the required dimensions. The covered drains are then made, and like the open drains, are done gradually. The following is the course pursued:—A narrow trench, just sufficient for a man to work in, is cut to the depth of 2 feet 6 inches; a shoulder is then left on each side, as in fig. 1, below which a narrow spit of turf is taken out (see drawing).

There are three operations, at intervals, in opening this drain, as in the open ones. First a deep spit (the top sod) is taken off, and laid carefully on the bank, as *a*. The whole of the field, or a number of fields is, or are, gone over thus; after which a second or third spit is taken off down to the shoulder, and laid upon the opposite bank, as *b*: the third operation is cutting the narrow spit, *c*, which is to serve for the drain, throwing the stuff out on the side *b*. When

all these operations are gone through, the top sod (*a*), put aside for the purpose, is carefully laid with the heathy side downwards upon the shoulders *d d*, as shown in fig. 2, and the other bog stuff *b*, fig. 1, thrown over it, as *b*, fig. 2.

These drains are made a perch asunder, at which distance there requires half a mile to each acre.* The acreable cost for the open drains is about 10s. and for the covered drains 35s., making a total per acre of 45s.

It was supposed these drains were sufficiently near to each other to do the business of draining effectually, but Mr. Baines has found it necessary to increase the number of covered drains; and he now is, or lately was, making the covered drains more numerous.

Experience has also shown that the drains were not sufficiently deep, for from the subsidence of the bog, from drainage and croppage, the drains now are not so deep as they were originally made; and it is the opinion, I understand, of Mr. Baines, and others, that the drains would have been better had they been made somewhat, deeper—not better as drains, but less liable to be injured by the treading of cattle.

The subject of bog reclamation in Ireland is attracting much attention, but as far as I know, I am not aware of its having yet paid any one, for the expense is very heavy. I have heard that some experiments have been lately made to drain bog by machinery, by Mr. Rigg, an English engineer, with considerable success, and great reduction in the expense. Perhaps some of your agricultural readers may know something of these experiments, and will favour the public by giving some information on the subject; or Mr. Rigg himself may do so if this meets his eye. I do not know the locality of the experiments.

The possibility of converting bog into a rich and fertile soil is proved beyond doubt, but the expense has been hitherto too great to induce proprietors to undertake its cultivation. Perhaps some of your correspondents may be able to give some hints on the subject, which I, for one, should be glad to learn.

I fear the expense of using timber as soling for tiles, together with the expense of tiles, must be too great to pay; except localities where land rents very high (as town parks). I should be happy to learn from your correspondent "An Irishman" what the expense is—length of drains in an acre—nature of bog—locality, with any other particulars it may be his convenience to give.

I am, Sir, your very obedient servant,
Dublin, Aug. 30, 1810. W. M.

* There are tools made on purpose for several of these operations.

DICTIONARY OF TERMS

USED IN AGRICULTURE AND ITS KINDRED SCIENCES.

ABRADING. This is a term applied by some agricultural writers to the crumbling down of earth from the effects of frost. This process is seen most on fall ploughed lands, and is an efficient agent in ameliorating and rendering fit for cultivation heavy or clay soils.

ABRASION. The wearing away, by running water, of earths, rocks, &c., the banks, or the bottom of streams, and the result of which is the deposit of alluvium.

ABSORPTION. The process by which plants and animals are nourished is called absorption. In most plants this office is performed by the roots, and it is through the vessels called spongioles, with which the roots are terminated, that absorption takes place. In aquatic plants, the water which affords the nourishment is absorbed with facility from every part of their surface. By causing the roots to imbibe coloured liquid, the general course of the sap may be traced with considerable accuracy.

ACIDS. Bodies that have usually a sour taste, and corrosive qualities. Some acids appear only in a fluid state, gaseous as carbonic acid, or liquid as sulphuric acid; others are crystallized, as the boric, benzoic, &c. Of the acids, the only one that has much influence on vegetation is the carbonic.

ACCLIMATING. Plants are endowed with a power of gradually accommodating themselves to the temperature or climate in which they are placed, unless the change is at once so great as to suspend their vital functions altogether. This process is called acclimating. Plants will bear removal better from a warm climate to one of lower temperature, than from a cold to a warm one. As instances in plants, we may mention the potato, the bean, the melon; and among fruits, the peach and apricot. The cucumber affords an instance of the effect of acclimation. It is grown in the open air at Cairo and at Petersburg, at Carracas and at Quebec.

AERATION. An important change effected on the sap of plants by the action of light. It consists in the decomposition of carbonic acid gas, which is either brought to the leaves of plants by the sap, or absorbed directly from the atmosphere. The substance of all plants is mostly carbon, and as carbon in its common state, however minutely divided, is never taken up by the sap of plants, this most essential ingredient is obtained in the form of the carbonic gas, from which the oxygen is separated by the leaves under the action of light, leaving the carbon ready for assimilation or conversion into vegetable fibre. That this process is performed by the green substance of the leaves or stem is evident from the fact that if a leaf is bruised or its vitality destroyed its substance is no longer capable of decomposing carbonic gas in the light, or absorbing oxygen in the dark. The necessity of this aeration of sap for the purpose of ripening fruit or maturing vegetation may be seen in some fruit trees, the plum for instance, in which an excessive quantity of fruit causes a premature fall of the leaves, after which, owing to this loss of the organs of aeration, the fruit never ripens, but remains immature and worthless. The necessity of the leaves for aeration, or perfecting the juices of plants, shows the

absurdity of plucking or injuring the leaves of any plant before it is ripe, topping corn, &c., under the idea of hastening maturity or increasing the product. Attempts to improve on nature must be failures.

AFTER-GRASS. The grass grown on meadows after they are mown. The usual practice among farmers is to feed this off by cattle or sheep, and in some cases so closely as to nearly destroy the roots of the grass. Unless the turf is close, and the meadow rich, it is better not to feed at all, or very lightly. For cropping after-grass, sheep are better than cattle, since, though their bite may be closer, they do not injure the roots with their feet, like the former. If mown a second time for rowen, it is called—

AFTER-MATH. On rich meadows, or where can be had in abundance for top-dressing, a second mowing may be justifiable, and the grass so cut, if well cured, is much relished, and eaten with avidity by ewes, calves, and other animals that are apt to become poor under ordinary management. The practice of the second mowing, however, like after feeding, is not to be recommended on the whole; experience proving that the injury grass roots always receive from mowing is increased by the second cutting. Necessity alone can render after feeding or mowing justifiable or proper.

AGRICULTURE. In the most extended use of this term, it is made to embrace all the operations made use of to obtain food for man, whether from the field, the orchard, or the garden. In its proper and limited sense it means the cultivation of the soil, which is the great source of wealth. The first want of man was food; the place to obtain it was the earth; hence the origin of agriculture; and in proportion to his wants and the ease or the difficulty with which they can be supplied is his progress in agriculture. Where the wants of man are supplied by the spontaneous productions of the earth, as in parts of Africa, or in the South Sea Islands; or where the inhabitants expect no food from the earth, as among the Esquimaux or Somofedes, there agriculture is unknown. It is only where exertion is necessary to procure food from the earth, that wants abound, that wealth is increased, and that agriculture becomes a science, and assumes its proper place as the basis and precursor of civilization, society, and order. All history proves that such is the fact. The creation of wealth belongs to agriculture. Food must be had, and the value of every other article depends directly or remotely on the amount of food it will procure. The skill of the mechanic may improve, the enterprise of the merchant may exchange, but the origin belongs to the earth, and the cost and the profit is alike determined by the result of agriculture.

Science has within a few years done much in aid of agriculture; not that many positive discoveries have in the first place been made by the sciences, of which the agriculturist has availed himself; but the cause of certain results before known to the farmer, have been revealed by chemical or other researches, and thus the means of more certainty and in many more cases of producing the same results has been obtained. On this is based the improved system of agriculture. Where the earths are not in due proportion, it is impossible to make or keep the soil in a productive state. The nature of the earths is now inquired into, and their balance maintained by a rotation of crops, or the application of such matters as

shall prevent exhaustion, or restore fertility to such as have been improperly treated. The capabilities of the earth in affording food, when properly tilled, are but imperfectly understood. Now and then instances occur in which either by skill or accident these powers are developed to the surprise of all; but what is done in one case may be done in others; and when agriculture is what it should be, when the tillage of the soil, and the application of proper manures shall be better understood, the results that now astonish will become common, and while the labour shall be diminished, the product will be vastly increased.

AIR. In a state of purity, air consists of nitrogen and oxygen, in the proportion of 76 of the former and 23 of the latter; but as it exists in the atmosphere, it contains about one part in 500 of carbonic gas, and also aqueous vapor in the form of an elastic fluid, the proportion varying from the merest trifle, to 11 grains in a cubic foot. Air acts a most important part in the processes of germination, and subsequent vegetation, not only furnishing the oxygen required to decompose the carbonic gas consumed by the plants, but most of the gas itself. The water held in the air is also easily parted with, and hence the great advantage of aeration or frequently stirring the earth, to bring its particles in contact with the atmosphere. A square foot of earth in a solid form exposes but a small surface to the action of the air, and hence absorbs from the atmosphere but little; pulverize this mass, and the surface exposed to the action of the air is increased a million fold, and its powers of absorption from the atmosphere in the same proportion. This shows the absurdity of those who refuse in hot or dry weather to stir the earth around plants under the apprehension that it will render them more dry. Multiplying the absorbing surface by stirring the earth is the only way of obtaining the moisture which in greater or less quantities always exists in the atmosphere.

ALBUMEN. A colourless insipid fluid, coagulating at a heat of 120°, existing in the leaves, juices, and fruits of most plants, but most abundant in animal products. The white of eggs is nothing but pure albumen, and the blood contains large quantities of the substance. Its principal use in domestic economy, is in clarifying or cleansing fluids; such as sugars, &c., for which purpose it is unrivalled. Milk contains albumen, and hence is sometimes used for cleaning syrup, but it is inferior to the whites of eggs. These carefully incorporated with a fluid when cold, and then submitted to a coagulating heat, will lift all impurities to the surface, where they can be easily taken off by skimming. Albumen is more abundant in the bark of the red or slippery elm, than in any other vegetable product, hence its value for medicinal purposes. Albumen is composed of carbon 52, oxygen 23, hydrogen 7, and nitrogen 15.

ALBURNUM. Wood of trees is usually composed of three distinct parts; the pith or central part, having a loose spongy texture; the heartwood, the most durable and valuable part of the tree; and the sap wood or alburnum. This last is usually whiter than the heartwood, is more porous, and through it the circulation of the sap is principally performed. It is the soonest attacked by the borer or powder post, and in exposed situations is always first to decay.

ALCOHOL. The purely spirituous part of all liquors. It is the product of vinous fermentation,

and can be derived from all substances capable of such fermentation. It is the intoxicating principle of liquors, and few nations have been found so rude as not to have found some means of producing it. Alcohol is produced principally by the distillation of wine, molasses and grain. The product of the first is brandy, the second rum, and the third whisky or gin. Alcohol is of much use in the arts, but it has, by its general use, produced a most unhappy effect on the happiness and morals of multitudes. Perhaps greater quantities of distilled spirits are used by the nations that border on the Baltic than in any other part of the world, and here they are principally produced from the distillation of potatoes. Pure alcohol consists of hydrogen 13.70; carbon 51.98; and oxygen 34.32.

ALGAE. One of the families of plants into which Linnaeus divided the vegetable kingdom. They are defined to be plants of which the roots, leaves and stem, are all one. The remains of algae are abundant in a fossil state in the shale of many parts of New York, and their decomposition may have contributed to the fertility of the strata in which they exist.

ALKALI. A substance usually extracted from plants, and distinguished by the following properties: It has an acrid and corrosive taste and power; it changes vegetable blue to a green, red to a purple, yellow to a red brown, and purple reduced by an acid to its original colour. It is most used in the arts for neutralizing acids. It is best known in the shape of potash and soda. These unite with oils and animal fat, and form soap. Lime is possessed of alkaline properties, which give it its principal value in many cases. Alkaline substances have been divided into volatile and fixed: the volatile being known as ammonia, the fixed as potash or soda. Modern chemists have divided them into 3 classes: 1, those with a metallic base combined with oxygen; potash, soda and lithia; 2, that which contains no oxygen, as ammonia; and 3, those containing oxygen, hydrogen and carbon, as aconita, circuta, morphia, &c.
